FOREWORD

The Book of A.S.T.M. Standards, of which this is the 1944 edition, is normally a triennial[1] publication, with Supplements issued in the intervening years. It contains the formally adopted A.S.T.M. Standards and the A.S.T.M. Tentative Standards as well. The present edition, in view of the War Emergency, also includes Emergency Standards and Emergency Alternate Provisions in A.S.T.M. Standards issued under an emergency procedure in the interest of expediting procurement or conservation of materials.

The Book is issued in three parts:

Part I, Metals.—Ferrous and non-ferrous metals (except methods of chemical analysis), general testing methods. The methods of chemical analysis of metals appear in a separate publication bearing that title.

Part II, Nonmetallic Materials—Constructional.—Cementitious materials, concrete and aggregates, masonry building units, pipe and tile, thermal insulating materials, refractories, glass, wood and wood preservatives, paints, varnishes and lacquers, naval stores, road materials, soils, waterproofing and roofing materials, fire tests, general testing methods, thermometers.

Part III, Nonmetallic Materials—General.—Coal and coke, petroleum products, paper, electrical insulating materials, plastics, rubber, textiles, soaps and detergents, naval stores, water, general testing methods, thermometers.

In these three parts are included the 1235 A.S.T.M. Standards and Tentative Standards in effect at the time of publication, exclusive of the 22 A.S.T.M. Methods of Chemical Analysis of Metals which appear in a separate publication bearing that title.

The annual Supplements issued to each part in the succeeding years will contain the newly adopted or revised Standards and new or revised Tentative Standards. These Supplements should be consulted for changes in status and for current revisions of Standards. The combined Index to Standards and Tentative Standards, issued annually, will also be helpful in this connection and in locating any desired standard.

Standards appear in the front of each part, and comprise those specifications and methods of test that have been formally adopted by the Society, requiring a letter ballot approval by the entire membership.

Tentative Standards, appearing in the back of each part, are published as tentative by the Society on the recommendation of the committee concerned, as representing the latest thoughts and practices, prior to adoption as standard.

Emergency Standards and *Emergency Alternate Provisions* are intended for use during the National Emergency where they may be considered as suitable for the specific application or use desired or as a permissible alternate for existing specifications.

The Emergency Standards and Emergency Alternate Provisions applying to the standards in this part of the Book of Standards appear in a separate section on pink colored stock in the middle of the book. For convenience, the Emergency Alternate Provisions may be cut out and attached to the standards to which they apply.

In accordance with Society regulations, standards that have been published for a period of six years or more without revision have been reviewed by the responsible standing committees prior to the appearance of the Book and have been reapproved in their present form.

The appearance of this Book is a tribute to the sincere efforts of the standing committees responsible for the development and review of the standards, and of the many individuals serving on the standing committees. (See list of committees appearing on page 1611.) The Society's time-tested standardization procedure provides for adequate representation on technical committees of producers and consumers and those having a general interest in the material or subject in question. Opportunity is provided during the period of promulgation for full consideration by all interested parties through publication as tentative before adoption as standard. As developments and advances take place, requirements are suitably revised.

GUIDE TO THE USE OF THE BOOK OF STANDARDS

THE standards in this Book are assembled in a sequence determined by the specific materials or products to which they apply. The Table of Contents in each part is presented in duplicate—one a list of standards in the order in which they appear, the other a list of the standards in numeric sequence of their serial designations. In addition, a separate listing (printed on green colored stock) is given of the tentative standards, just preceding that portion of the Book (see page opposite 1202). The Tentative Revisions of Standards appear in a separate section beginning on page 1601.

Emergency Standards and Emergency Alternate Provisions applying to the standards in this book appear in the pink colored insert section beginning on page 1172.

A subject index of the standards and tentative standards in this part appears at the back of this volume (see page 1613). This index should be the most convenient means of locating any standard appearing in the volume, especially if only the general subject matter covered is known.

A separate combined Index, covering all standards and tentative standards in Parts I, II, and III of the Book of A.S.T.M. Standards, in the annual Supplements thereto, and in the book of A.S.T.M. Methods of Chemical Analysis of Metals, is also issued annually, which should be of convenience to all users of the Book of Standards. The combined Index will be revised annually to incorporate the latest references to the standards, whether they appear in the Book of Standards or in the 1945 or 1946 Supplements. The combined Index will be particularly helpful after one of the Supplements has been issued.

Comments or suggestions intended to improve the utility of the Book of Standards will be welcome.

CONTENTS

BOOK OF A.S.T.M. STANDARDS, PART II

Nonmetallic Materials—Constructional

(For standards covering other nonmetallic materials, see Part III)

In the serial designations prefixed to the following titles, the initial letter, indicative of the general classification, and the first number are permanent. The number following the dash indicates the year of original issue as tentative or of adoption as standard or, in the case of revision, the year of last revision. Thus, standards adopted or revised during the year 1944 have as their final number, 44. Tentative standards are identified by the letter T.

Emergency Standards appear in a separate section beginning on p. 1172, and are printed on colored stock. They are identified by the letters ES in their serial designation. A letter following the number indicates revisions made subsequent to the original date of issue, for example, a for the first revision, b for the second, etc.

Emergency Alternate Provisions also appear in a separate section beginning on p. 1172 and are identified by the letters EA followed by the permanent designation of the standard to which they apply.

In the following listing, the standards are grouped according to materials to which they apply. Listings of Tentative Standards appear in italics.

For Contents in Numeric Sequence, see p. xxvi.

For a list of Emergency Standards and Emergency Alternate Provisions, see p. 1172.

The Tentative Standards are listed separately in the green insert opposite p. 1202.

Tentative Revisions of Standards are listed on p. 1601.

A complete subject index appears on p. 1613.

CEMENTITIOUS MATERIALS

Cement

Specifications for:		PAGE
C 150 – 44.	Portland Cement	1
EA – C 150.	*(Portland Cement) Discontinued.*	
C 175 – 44 T.	*Air-Entraining Portland Cement for Concrete Pavements (Tentative)*	1203
C 10 – 37.	Natural Cement	5
C 91 – 40.	Masonry Cement	7
C 91 – 44 T.	*Masonry Cement (Tentative)*[1]	1206
Methods of:		
C 114 – 44.	Chemical Analysis of Portland Cement	14
C 114 – 44 T.	*Chemical Analysis of Portland Cement (Tentative)*[2]	1214

[1] This is in effect a tentative revision of, and, when adopted, is to replace Standard Specifications C 91 – 40.
[2] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Methods C 114 – 44.

For Contents in Numeric Sequence, see p. xxvi.

Methods of:		PAGE
C 77.	(*Sampling and Physical Testing of Portland Cement*) *Discontinued, Replaced by Methods C 183, C 184, C 187, C 188, C 189, C 190, and C 191.*	
C 183 – 44.	Sampling Hydraulic Cement	42
C 151 – 43.	Autoclave Expansion of Portland Cement, Test for	44
C 115 – 42.	Fineness of Portland Cement by the Turbidimeter, Test for	47
C 184 – 44.	Fineness of Hydraulic Cement by the No. 200 Sieve, Test for	55
C 187 – 44.	Normal Consistency of Hydraulic Cement, Test for	58
C 189 – 44.	Soundness of Hydraulic Cement over Boiling Water (Pat Test), Test for	61
C 188 – 44.	Specific Gravity of Hydraulic Cement, Test for	64
C 191 – 44.	Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles, Tests for	66
C 190 – 44.	Tensile Strength of Hydraulic-Cement Mortars, Test for	70
C 109 – 44.	Compressive Strength of Hydraulic-Cement Mortars, Test for	76
C 185 – 44 T.	*Air Content of Portland-Cement Mortar, Test for (Tentative)*	1227
C 186 – 44 T.	*Heat of Hydration of Portland Cement, Test for (Tentative)*	1231
C 85 – 42.	Cement Content of Hardened Portland-Cement Concrete, Test for	464

Lime

Specifications for:		
C 5 – 26.	Quicklime for Structural Purposes	83
C 6 – 44.	Normal Finishing Hydrated Lime	85
C 141 – 42.	Hydraulic Hydrated Lime for Structural Purposes	87
C 45 – 25.	Quicklime and Hydrated Lime for Cooking of Rags in Paper Manufacture	92
C 46 – 27.	Quicklime for Sulfite Pulp Manufacture	94
C 47 – 27.	Hydrated Lime for Varnish Manufacture	96
C 48 – 24.	Quicklime and Hydrated Lime for Use in the Textile Industry	98
C 49 – 42.	Quicklime and Hydrated Lime for Silica Brick Manufacture	100
C 53 – 39.	Quicklime and Hydrated Lime for Water Treatment	101
C 35 – 39.	Sand for Use in Plaster	103
Methods of:		
C 50 – 27.	Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products	105
C 25 – 44.	Chemical Analysis of Limestone, Quicklime, and Hydrated Lime	109
C 110 – 38 T.	*Physical Testing of Quicklime and Hydrated Lime (Tentative)*	1238
†C 19 – 41.	Fire Tests of Building Construction and Materials	234
Definitions of:		
C 51 – 44.	Lime, Terms Relating to	121
C 51 – 44 T.	*Lime, Terms Relating to (Tentative)*[3]	1243

Gypsum

Specifications for:		
†C 22 – 41.	Gypsum	122
†C 28 – 40.	Gypsum Plasters	124
†C 59 – 40.	Gypsum Molding Plaster	127
†C 60 – 40.	Gypsum Pottery Plaster	129
†C 61 – 40.	Keene's Cement	131
††C 72 – 40.	Gypsum, Calcined, for Dental Plasters	133
C 35 – 39.	Sand for Use in Plaster	103

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.
[3] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Definitions C 51 – 44.

For Contents in Numeric Sequence, see p. xxvi.

		PAGE
Specifications for:		
†C 36 – 42.	Gypsum Wall Board	135
†C 37 – 42.	Gypsum Lath	137
†C 79 – 42.	Gypsum Sheathing Board	139
†C 52 – 41.	Gypsum Partition Tile or Block	141
Methods of:		
††C 26 – 42.	Testing Gypsum and Gypsum Products	144
†C 19 – 41.	Fire Tests of Building Construction and Materials	234
Definitions of:		
C 11 – 41.	Gypsum, Terms Relating to	158
C 11 – 41 T.	*Gypsum, Terms Relating to (Tentative)*[4]	1244

MASONRY BUILDING UNITS, STONE, AND SLATE

Brick

Specifications for:		
†C 55 – 37.	Building Brick, Concrete	160
C 62 – 44.	Building Brick (Made from Clay or Shale)	162
†C 73 – 39.	Building Brick, Sand-Lime	167
C 126 – 44 T.	*Masonry Units, Glazed (Tentative)*	1245
C 7 – 42.	Paving Brick	169
C 32 – 42.	Sewer Brick (Made from Clay or Shale)	176
Methods of:		
†C 67 – 44.	Sampling and Testing Brick	178

Structural Tile and Filter Block

Specifications for:		
†C 34 – 41.	Clay Load-Bearing Wall Tile, Structural	187
†C 56 – 41.	Clay Non-Load-Bearing Tile, Structural	190
†C 57 – 39.	Clay Floor Tile, Structural	193
C 126 – 44 T.	*Masonry Units, Glazed (Tentative)*	1245
C 52 – 41.	Gypsum Partition Tile or Block	141
C 159 – 41 T.	*Filter Block, Vitrified Clay, for Trickling Filters (Tentative)*	1250
Methods of:		
†C 112 – 36.	Sampling and Testing Structural Clay Tile	196
Definitions of:		
C 43 – 36.	Structural Clay Tile, Terms Relating to	200

Concrete Masonry Units

Specifications for:		
†C 90 – 44.	Concrete Masonry Units, Hollow Load-Bearing	202
†C 129 – 39.	Concrete Masonry Units, Hollow Non-Load-Bearing	204
†C 145 – 40.	Concrete Masonry Units, Solid Load-Bearing	206
†C 139 – 39.	Concrete Masonry Units for Construction of Catch Basins and Manholes	208
†C 55 – 37.	Concrete Building Brick	160
Methods of:		
†C 140 – 39.	Sampling and Testing Concrete Masonry Units	210

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.
[4] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Definitions C 11 – 41.

For Contents in Numeric Sequence, see p. xxvi.

Building Stone and Slate

		PAGE
Methods of:		
C 97 – 36.	Natural Building Stone, Absorption and Apparent Specific Gravity of, Tests for	213
C 99 – 36.	Natural Building Stone, Flexure Testing of (Determination of Modulus of Rupture)	215
C 100 – 36.	Natural Building Stone, Modulus of Elasticity of, Test for	217
C 102 – 36.	Natural Building Stone, Shear Testing of	221
C 170 – 41 T.	*Natural Building Stone, Compressive Strength of, Test for (Tentative)*	1253
C 120 – 31.	Slate, Flexure Testing of (Modulus of Rupture, Modulus of Elasticity)	226
C 121 – 31.	Slate, Water Absorption of, Test for	229
D 273 – 40.	Slate, Electrical, Tests for Conducting Paths in (see Part III, p. 492).	
Definition of:		
C 119 – 27.	Slate, Term	231

MORTAR FOR UNIT MASONRY

Specifications for:		
C 144 – 44.	Aggregate for Masonry Mortar	232
C 161 – 44 T.	*Mortar for Reinforced Brick Masonry (Tentative)*	1256

FIRE TESTS

Specifications for:		
C 132.	*(Fire-Retardant Properties of Wood for Scaffolding and Shoring) Discontinued.*	
D 626 – 41 T.	*Fire-Retardant Properties of Treated Textile Fabrics (Tentative) (see Part III).*	
Methods of:		
†C 19 – 41.	Fire Tests of Building Construction and Materials	234
†C 152 – 41.	Fire Tests of Door Assemblies	241
C 160 – 41 T.	*Fire-Retardant Properties of Wood, Test for (Tentative)*	1259
D 568 – 43.	Flammability of Plastics 0.050 in. and Under in Thickness, Test for (see Part III, p. 524).	
D 635 – 44.	Flammability of Plastics Over 0.050 in. in Thickness, Test for (see Part III, p. 527).	

THERMAL INSULATING MATERIALS

Specifications for:		
C 193 – 44 T.	*85 per cent Magnesia Thermal Insulating Cement (Tentative)*[5]	1264
C 194 – 44 T.	*Asbestos Thermal Insulating Cement (Tentative)*[6]	1266
C 195 – 44 T.	*Mineral Wool Thermal Insulating Cement (Tentative)*[7]	1268
C 196 – 44 T.	*Expanded or Exfoliated Vermiculite Thermal Insulating Cement (Tentative)*[8]	1271
C 197 – 44 T.	*Diatomaceous Silica Thermal Insulating Cement (Tentative)*[9]	1274
ES – 14.	*Blanket Thermal Insulation for Building Purposes (Emergency Specifications)*	1173
ES – 15.	*Blanket Thermal Insulation for Industrial Purposes (Emergency Specifications)*	1175

† Approved as **American Standard** by the American Standards Association.
[5] These specifications were formerly published as Emergency Specifications ES – 8.
[6] These specifications were formerly published as Emergency Specifications ES – 9.
[7] These specifications were formerly published as Emergency Specifications ES – 10.
[8] These specifications were formerly published as Emergency Specifications ES – 11.
[9] These specifications represent a consolidation of the former Emergency Specifications ES – 12 and ES – 13.

For Contents in Numeric Sequence, see p. xxvi.

Specifications for:		
ES – 16.	*Blanket Thermal Insulation for Refrigeration Purposes (Emergency Specifications)*	1177
ES – 17.	*Pipe Covering, Preformed, Thermal Insulation (Emergency Specifications)*	1179
ES – 18.	*Block, Preformed, Thermal Insulation (Emergency Specifications).*	1182
ES – 19.	*Board, Structural Insulating (Thermal Insulation) (Emergency Specifications)*	1185
Methods of:		
C 163 – 44.	Sampling and Mixing Thermal Insulating Cement	246
C 164 – 44.	Bulk Density of Thermal Insulating Cement, Test for	248
C 166 – 41 T.	*Covering Capacity and Volume Change Upon Drying of Thermal Insulating Cement, Tests for (Tentative)*	1276
C 165 – 41 T.	*Compressive Strength and Flexural Strength of Preformed Block Type Thermal Insulating Materials, Tests for (Tentative)*	1279
C 167 – 44.	Thickness and Density of Blanket Type Thermal Insulating Materials, Tests for	250
C 177 – 42 T.	*Thermal Conductivity of Materials by Means of the Guarded Hot Plate, Test for (Tentative)*	1282
Definitions of:		
C 168 – 44.	Thermal Insulating Materials, Terms Relating to	252
	REFRACTORIES, FIRE BRICK	
Specifications for:		
C 64 – 41.	Refractories for Heavy Duty Stationary Boiler Service	253
C 153 – 41.	Refractories for Moderate Duty Stationary Boiler Service	257
C 106 – 41.	Refractories for Incinerators	259
C 63 – 41.	Refractories for Malleable Iron Furnaces with Removable Bungs and for Annealing Ovens	262
C 176 – 44.	Fireclay Plastic Refractories for Boiler and Incinerator Services	265
C 178 – 44 T.	*Air-Setting Refractory Mortars (Wet Type) for Boiler and Incinerator Services (Tentative)*	1291
‡C 105 – 41.	Ground Fire Clay as a Mortar for Laying-Up Fireclay Brick	267
C 49 – 42.	Quicklime and Hydrated Lime for Silica Brick Manufacture	100
Classifications of:		
C 27 – 41.	Fireclay Refractories	269
C 155 – 41 T.	*Insulating Back-Up Block and Insulating Fire Brick (Tentative)*	1294
Methods of:		
C 18 – 41.	Chemical Analysis of Refractory Materials	271
‡C 24 – 42.	Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials, Test for	294
‡C 38 – 42.	Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick	297
‡C 107 – 42.	Panel Test for Resistance to Thermal and Structural Spalling of High Heat Duty Fireclay Brick	304
‡C 122 – 42.	Panel Test for Resistance to Thermal and Structural Spalling of Super Duty Fireclay Brick	306
C 180 – 43 T.	*Panel Test for Resistance to Thermal and Structural Spalling of Fireclay Plastic Refractories (Tentative)*	1295
C 113 – 36.	Permanent Linear Change After Reheating of Refractory Brick, Test for	308
C 179 – 43 T.	*Drying and Firing Shrinkage, Combined, of Fireclay Plastic Refractories, Test for (Tentative)*	1297

‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

For Contents in Numeric Sequence, see p. xxvi.

†C 145 – 40. Masonry Units, Concrete, Solid Load-Bearing ... 206

† Approved as **American Standard** by the American Standards Association.

[10] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Definitions C 58 – 28.

For Contents in Numeric Sequence, see p. xxvi.

		PAGE
Specifications for:		
†C 139 – 39.	Masonry Units, Concrete, for Construction of Catch Basins and Manholes	208
†C 4 – 24.	Drain Tile	371
C 14 – 41.	Sewer Pipe, Concrete	386
C 75 – 41.	Sewer Pipe, Reinforced Concrete	394
C 76 – 41.	Culvert Pipe, Reinforced Concrete	404
C 118 – 39.	Irrigation Pipe, Concrete	415
Methods of:		
C 42 – 44.	Specimens from Hardened Concrete, Securing, Preparing, and Testing for Compressive and Flexural Strengths	460
†C 140 – 39.	Concrete Masonry Units, Sampling and Testing of	210
C 172 – 44.	Sampling of Fresh Concrete	463
C 173 – 42 T.	*Air Content (Volumetric) of Freshly Mixed Concrete, Test for (Tentative)*	1340
C 85 – 42.	Cement Content of Hardened Portland-Cement Concrete, Test for	464
C 31 – 44.	Making and Curing Concrete Compression and Flexure Test Specimens in the Field	466
C 192 – 44 T.	*Making and Curing Concrete Compression and Flexure Test Specimens in the Laboratory (Tentative)*	1344
C 39 – 44.	Compressive Strength of Molded Concrete Cylinders, Test for	470
C 116 – 44.	Compressive Strength of Concrete Using Portions of Beams Broken in Flexure (Modified Cube Method), Test for	472
C 124 – 39.	Flow of Portland-Cement Concrete by Use of the Flow Table, Test for	474
C 143 – 39.	Consistency of Portland-Cement Concrete, Slump Test for	476
C 174 – 44.	Measuring Length of Drilled Concrete Cores	478
C 78 – 44.	Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading), Test for	480
C 157 – 43.	Volume Change of Cement Mortar and Concrete, Test for	483
C 138 – 44.	Weight per Cubic Foot, Yield, and Air Content (Gravimetric) of Concrete, Test for	487
†C 19 – 41.	Fire Tests of Building Construction and Materials	234
Definitions of:		
C 125 – 44.	Concrete and Concrete Aggregates, Terms Relating to	490
	Curing Concrete	
Specifications for:		
C 111 – 36.	Sodium Silicate for Curing Concrete	491
C 171 – 42 T.	*Waterproof Paper for Curing Concrete (Tentative)*	1349
D 98 – 34.	Calcium Chloride	511
D 632 – 43.	Sodium Chloride	512
Methods of:		
C 156 – 44 T.	*Water Retention Efficiency of Methods for Curing Concrete, Test for (Tentative)*	1351
‡D 345 – 34.	Chemical Analysis of Calcium Chloride	522
	ROAD AND PAVING MATERIALS	
	(See also **Soils**)	
	Nonbituminous Road Materials	
Specifications for:		
D 448 – 42 T.	*Coarse Aggregate for Highway Construction, Standard Sizes (Tentative)*	1355

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

For Contents in Numeric Sequence, see p. xxvi.

Specifications for:		PAGE
C 33 – 44.	Concrete Aggregates	423
D 556 – 40 T.	*Materials for Stabilized Base Course (Tentative)*	1357
D 557 – 40 T.	*Materials for Stabilized Surface Course (Tentative)*	1359
D 692 – 42 T.	*Crushed Stone, Crushed Slag, and Gravel for Bituminous Concrete Base and Surface Courses of Pavements (Tentative)*	1361
D 693 – 44.	Crushed Stone and Crushed Slag for Bituminous Macadam Base and Surface Courses of Pavements	492
D 694 – 44.	Crushed Stone, Crushed Slag, and Gravel for Water-Bound Macadam Base and Surface Courses of Pavements	495
D 59 – 39.	Granite Block for Pavements	497
D 131 – 39.	Granite Block, Recut, for Pavements	499
D 132 – 39.	Granite Block for Durax Pavements	501
D 52 – 20.	Wooden Paving Blocks for Exposed Pavements	708
C 7 – 42.	Paving Brick	169
†D 57 – 20.	Cement Grout Filler for Brick and Stone Block Pavements, Materials for	503
D 58 – 37.	Sand-Cement Bed for Brick and Block Pavements, Materials for	505
D 242 – 39.	Mineral Filler for Sheet Asphalt and Bituminous Concrete Pavements	507
D 162 – 29.	Sand for Sheet Asphalt and Bituminous Concrete Pavements	508
‡D 544 – 41.	Expansion Joint Fillers, Preformed, for Concrete (Nonextruding and Resilient Types)	509
D 98 – 34.	Calcium Chloride	511
D 632 – 43.	Sodium Chloride	512
C 111 – 36.	Sodium Silicate for Curing Concrete	491
C 94 – 44.	Concrete, Ready-Mixed	453
C 175 – 44 T.	*Air-Entraining Portland Cement for Concrete Pavements (Tentative)*	1203
C 171 – 42 T.	*Waterproof Paper for Curing Concrete (Tentative)*	1349
†E 11 – 39.	Sieves for Testing Purposes	1146
Methods of:		
D 75 – 42 T.	*Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (Tentative)*	1364
C 172 – 44.	Sampling Fresh Concrete	463
C 42 – 44.	Specimens from Hardened Concrete, Securing, Preparing, and Testing for Compressive and Flexural Strengths	460
D 2 – 33.	Abrasion of Rock by Use of the Deval Machine, Test for	513
†D 3 – 18.	Toughness of Rock, Test for	514
D 289 – 42 T.	*Abrasion of Gravel by Use of the Deval Machine, Test for (Tentative)*	1369
†C 131 – 44.	Abrasion of Coarse Aggregate by Use of the Los Angeles Machine, Test for	431
C 142 – 39.	Clay Lumps in Aggregates, Test for	434
C 123 – 44.	Coal and Lignite in Sand, Test for	436
†D 546 – 41.	Sieve Analysis of Mineral Filler, Test for	516
†C 117 – 37.	Amount of Material Finer than No. 200 Sieve in Aggregates, Test for	439
†C 136 – 39.	Sieve Analysis of Fine and Coarse Aggregates, Test for	441
C 88 – 44 T.	*Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate, Test for (Tentative)*	1332
†C 127 – 42.	Specific Gravity and Absorption of Coarse Aggregate, Test for	443
†C 128 – 42.	Specific Gravity and Absorption of Fine Aggregate, Test for	445
C 29 – 42.	Unit Weight of Aggregate, Test for	449
†C 30 – 37.	Voids in Aggregate for Concrete, Test for	451
C 173 – 42 T.	*Air Content (Volumetric) of Freshly Mixed Concrete, Test for (Tentative)*	1340

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

For Contents in Numeric Sequence, see p. xxvi.

Methods of:		PAGE
C 174 – 44.	Concrete Cores, Drilled, Measuring Length of	478
C 78 – 44.	Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading), Test for	480
C 124 – 39.	Flow of Portland-Cement Concrete by Use of the Flow Table, Test for	474
C 143 – 39.	Slump Test for Consistency of Portland-Cement Concrete	476
C 85 – 42.	Cement Content of Hardened Portland-Cement Concrete, Test for	464
C 31 – 44.	Making and Curing Concrete Compression and Flexure Test Specimens in the Field	466
C 39 – 44.	Compressive Strength of Molded Concrete Cylinders, Test for	470
C 116 – 44.	Compressive Strength of Concrete Using Portions of Beams Broken in Flexure (Modified Cube Method), Test for	472
C 157 – 43.	Volume Change of Cement Mortar and Concrete, Test for	483
C 138 – 44.	Method of Test for Weight Per Cubic Foot, Yield, and Air Content (Gravimetric) of Concrete	487
‡D 545 – 41.	Preformed Expansion Joint Fillers for Concrete (Nonextruding and Resilient Types), Testing of	518
‡D 345 – 34.	Chemical Analysis of Calcium Chloride	522
C 156 – 44 T.	*Water Retention Efficiency of Methods for Curing Concrete, Test for (Tentative)*	1351
Definitions of:		
D 8 – 33.	Materials for Roads and Pavements, Terms Relating to	611
C 58 – 28.	Sand, Term	452
C 125 – 44.	Concrete and Concrete Aggregates, Terms Relating to	490
C 58 – 28 T.	*Aggregate, Term (Tentative)*[10]	1339
E 12 – 27.	Specific Gravity, Terms Relating to	1167
E 13 – 42.	Screen (Sieve), Term	1169

Bituminous Road Materials

Specifications for:		
D 631 – 43.	Emulsified Asphalt, Slow-Setting (for Fine Aggregate Mixes)	526
D 397 – 39.	Emulsified Asphalt, Medium-Setting (for Coarse Aggregate Plant Mixes)	528
D 398 – 39.	Emulsified Asphalt, Medium-Setting (for Retread and Coarse Aggregate Mixes)	530
D 399 – 39.	Emulsified Asphalt, Medium-Setting (Heavy Premix—Summer Grade)	532
D 401 – 40.	Emulsified Asphalt, Quick-Setting (for Penetration and Surface Treatment)	534
D 597 – 40 T.	*Cut-Back Asphalt (Rapid Curing Type) (Tentative)*	1372
D 598 – 40 T.	*Cut-Back Asphalt (Medium Curing Type) (Tentative)*	1374
D 490 – 43 T.	*Tar (Tentative)*	1376
D 241 – 43.	Asphalt Filler for Brick Pavements	536
D 112 – 30.	Coal-Tar Pitch for Stone Block Filler	538
D 517 – 40.	Asphalt Plank	539
Methods of:		
D 140 – 41 T.	*Sampling Bituminous Materials (Tentative)*	1379
†D 4 – 42.	Bitumen, Determination of	543
†D 165 – 42.	Bitumen Soluble in Carbon Tetrachloride, Test for Proportion of	546
†D 20 – 30.	Distillation of Tar Products Suitable for Road Treatment, Test for	548
D 402 – 36.	Distillation of Cut-Back Asphaltic Products, Test for	552
†D 113 – 44.	Ductility of Bituminous Materials, Test for	556
D 244 – 42.	Emulsified Asphalts, Testing of	559

‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

† Approved as **American Standard** by the American Standards Association.

For Contents in Numeric Sequence, see p. xxvi.

		PAGE
Methods of:		
†D 139 – 27.	Float Test for Bituminous Materials	570
D 6 – 39 T.	*Loss on Heating of Oil and Asphaltic Compounds, Test for (Tentative)*	1383
D 762 – 44 T.	*Hot Extraction of Asphaltic Materials and Recovery of Bitumen by the Modified Abson Procedure, Test for (Tentative)*	1386
†D 5 – 25.	Penetration of Bituminous Materials, Test for	573
†D 243 – 36.	Residue of Specified Penetration, Test for	575
†D 36 – 26.	Softening Point of Bituminous Materials (Ring-and-Ball Method), Test for	578
E 28 – 42 T.	*Softening Point (Ball and Shouldered Ring Apparatus), Test for (Tentative)*	1580
D 61 – 38.	Softening Point of Tar Products (Cube-in-Water Method), Test for	581
D 71 – 27.	Specific Gravity of Asphalts and Tar Pitches Sufficiently Solid to Be Handled in Fragments, Test for	584
D 70 – 27.	Specific Gravity of Road Oils, Road Tars, Asphalt Cements, and Soft Tar Pitches, Test for	586
†D 88 – 44.	Viscosity by Means of the Saybolt Viscosimeter, Test for	588
†D 666 – 44.	Viscosity, Conversion of Kinematic to Saybolt Furol	593
†D 567 – 41.	Calculating Viscosity Index (see Part III, p. 273).	
†D 206 – 36.	Volume Correction Table, Abridged, for Petroleum Oils	594
D 633 – 44.	Volume Correction Table for Tar and Coal-Tar Pitch	666
†D 95 – 40.	Water in Petroleum Products and Other Bituminous Materials, Test for	599
Recommended Practice for:		
D 290 – 39.	Bituminous Paving Plant Inspection	603
Definitions of:		
D 8 – 33.	Materials for Roads and Pavements, Terms Relating to	611
E 12 – 27.	Specific Gravity, Terms Relating to	1167

SOILS

Methods of:		
D 420 – 42 T.	*Surveying and Sampling Soils for Highway Subgrades (Tentative)*	1390
D 421 – 39.	Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants	614
‡D 422 – 39.	Mechanical Analysis of Soils	616
D 423 – 39.	Liquid Limit of Soils, Test for	626
D 424 – 39.	Plastic Limit and Plasticity Index of Soils, Test for	629
D 425 – 39.	Centrifuge Moisture Equivalent of Soils, Test for	631
D 426 – 39.	Field Moisture Equivalent of Soils, Test for	634
D 427 – 39.	Shrinkage Factors of Soils, Test for	636
D 698 – 42 T.	*Moisture-Density Relations of Soils, Test for (Tentative)*	1399
D 558 – 44.	Soil-Cement Mixtures, Moisture-Density Relations of, Test for	640
D 559 – 44.	Soil-Cement Mixtures, Compacted, Wetting-and-Drying Test	643
D 560 – 44.	Soil-Cement Mixtures, Compacted, Freezing-and-Thawing Test	647
D 806 – 44 T.	*Soil-Cement Mixtures, Cement Content of, Test for (Tentative)*	1402
Definitions of:		
D 653 – 42 T.	*Soil Mechanics, Terms and Symbols Relating to (Tentative)*	1406

WATERPROOFING AND ROOFING MATERIALS

Asphalt, Pitch, and Primers

Specifications for:		
D 312 – 44.	Asphalt for Use in Constructing Built-Up Roof Coverings	651
D 449 – 42 T.	*Asphalt for Dampproofing and Waterproofing (Tentative)*	1413

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

For Contents in Numeric Sequence, see p. xxvi.

Specifications for: PAGE

D 450 – 41. Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing. 654
D 654 – 42 T. *Coal-Tar Pitch for Steep Built-Up Roofs (Tentative)*. 1416
D 41 – 41. Primer for Use with Asphalt in Dampproofing and Waterproofing. 657
D 43 – 41. Creosote for Priming Coat with Coal-Tar Pitch in Dampproofing and Waterproofing. 659

Methods of:

D 140 – 41 T. *Sampling Bituminous Materials (Tentative)*. 1379
D 255 – 28. Distillation, Steam, of Bituminous Protective Coatings, Test for. 661
D 244 – 42. Emulsified Asphalts, Testing of. 559
D 466 – 42. Films Deposited from Bituminous Emulsions, Testing of. 664
†D 206 – 36. Volume Correction Table, Abridged, for Petroleum Oils. 594
D 633 – 44. Volume Correction Table for Tar and Coal-Tar Pitch. 666

Bituminous Grouts, Mastics, and Saturated Materials

Specifications for:

D 491 – 41. Asphalt Mastic for Use in Waterproofing (Asphalt Cement, Mineral Filler, Mineral Aggregate). 670
D 170 – 41. Bituminous Grout for Use in Waterproofing Above Ground Level. 672
D 171 – 41. Bituminous Grout for Use in Waterproofing Below Ground Level. 674
D 250 – 44 T. *Asphalt-Saturated Asbestos Felts for Use in Waterproofing and in Constructing Built-Up Roofs (Tentative)*. 1418
D 655 – 44 T. *Asphalt-Saturated and Coated Asbestos Felts for Use in Constructing Built-Up Roofs (Tentative)*. 1420
D 226 – 44. Asphalt-Saturated Roofing Felt for Use in Waterproofing and in Constructing Built-Up Roofs. 676
D 227 – 44. Coal-Tar Saturated Roofing Felt for Use in Waterproofing and in Constructing Built-Up Roofs. 679
D 173 – 44. Fabrics, Woven Cotton, Saturated with Bituminous Substances for Use in Waterproofing. 682
D 371 – 44. Wide Selvage Asphalt Roofing Surfaced with Coarse Mineral Granules. 685
**D 249 – 44 T.* *Asphalt Roofing Surfaced with Coarse Mineral Granules (Tentative)*. 1423
**D 224 – 44 T.* *Asphalt Roofing Surfaced with Powdered Talc or Mica (Tentative)*. 1427
D 225 – 44 T. *Asphalt Shingles Surfaced with Coarse Mineral Granules (Tentative)*. 1430
D 699 – 44. Asphalt Siding Surfaced with Coarse Mineral Granules. 688

Methods of:

**D 147 – 41.* Bituminous Mastics, Grouts, and Like Mixtures, Testing of. 691
D 313 – 41. Coarse Particles in Mixtures of Asphalt and Mineral Matter, Test for. 696
D 451 – 40. Sieve Analysis of Granular Mineral Surfacing for Asphalt Roofing and Shingles, Test for. 698
D 452 – 40. Sieve Analysis of Nongranular Mineral Surfacing for Asphalt Roofing and Shingles, Test for. 701
D 146 – 44 T. *Fabrics, Felted and Woven, Saturated with Bituminous Substances for Use in Waterproofing and Roofing, Testing of (Tentative)*. 1433
D 228 – 44 T. *Asphalt Roll Roofing, Cap Sheets, and Shingles, Testing of (Tentative)*. 1440

† Approved as **American Standard** by the American Standards Association.
* Emergency Alternate Provisions applying to this standard have been issued and appear in the pink section of this book, see p. 1172.

For Contents in Numeric Sequence, see p. xxvi.

		PAGE
Methods of:		
D 727 – 43 T.	*Roofing and Flooring Felt, Test for Kerosine Number by Vacuum Method (Tentative)*	1447
D 762 – 44 T.	*Hot Extraction of Asphaltic Materials and Recovery of Bitumen by the Modified Abson Procedure, Test for (Tentative)*	1386
Recommended Practice for:		
D 529 – 39 T.	*Accelerated Weathering Test of Bituminous Materials (Tentative)*	1449

WOOD AND WOOD PRESERVATIVES

Wood

Specifications for:		
†D 25 – 37.	Timber Piles, Round	704
D 52 – 20.	Paving Blocks, Wooden, for Exposed Pavements	708
†D 245 – 37.	Structural Wood Joist and Plank, Beams and Stringers, and Posts and Timbers	711
D 358 – 44 T.	*Wood to be Used as Panels in Weathering Tests of Paints and Varnishes (Tentative)*	1555
Methods of:		
†D 143 – 27.	Small Clear Specimens of Timber, Testing of	730
†D 198 – 27.	Static Tests of Timbers in Structural Sizes	761
D 805 – 44 T.	*Veneer, Plywood, and Other Wood and Wood-Base Materials, Testing of (Tentative)*	1453
Definitions of:		
D 9 – 30.	Timber, Terms Relating to	777

Wood Preservatives

Specifications for:		
D 390 – 36.	Creosote	783
D 391 – 36.	Creosote - Coal Tar Solution	785
D 432 – 39.	Zinc Chloride	787
Methods of:		
D 38 – 33.	Sampling and Testing Creosote	788
D 168 – 30.	Coke Residue of Creosote, Test for	791
†D 139 – 27.	Float Test for Bituminous Materials	570
D 246 – 42.	Distillation of Creosote, Test for	793
D 367 – 33.	Insoluble Matter in Creosote, Tests for	799
D 368 – 33.	Specific Gravity of Creosote, Test for	801
D 369 – 33.	Specific Gravity, 38/15.5 C., of Creosote Fractions, Test for	803
D 370 – 33.	Water in Creosote, Test for	805
D 453 – 41.	Tar Acids in Creosote and Creosote - Coal Tar Solutions, Test for	808
D 347 – 33.	Volume and Specific Gravity Correction Tables for Creosote and Coal Tar	811
D 199 – 27.	Chemi al Analysis of Zinc Chloride	814
Definitions of:		
D 324 – 41.	Timber Preservatives, Terms Relating to	817

PAINT, VARNISH, LACQUER, AND RELATED PRODUCTS

White Pigments

Specifications for:		
†D 79 – 44.	Zinc Oxide	818
D 80 – 41.	Zinc Oxide, Leaded	820

† Approved as **American Standard** by the American Standards Association.

For Contents in Numeric Sequence, see p. xxvi.

Specifications for:		PAGE
†D 81 – 43.	White Lead, Basic Carbonate	822
D 82 – 44.	White Lead, Basic Sulfate	824
†D 476 – 41.	Titanium Dioxide Pigments	826
‡D 477 – 41.	Zinc Sulfide Pigments	828
D 602 – 42.	Barium Sulfate Pigments	830
D 603 – 42.	Aluminum Silicate Pigment	831
D 604 – 42.	Diatomaceous Silica Pigment	832
D 605 – 42.	Magnesium Silicate Pigment	833
D 606 – 42.	Lead Titanate	834
*D 607 – 42.	Mica Pigment	835

Black Pigments

Specifications for:		
†D 209 – 41.	Lampblack	836
†D 210 – 41.	Bone Black	838
†D 405 – 41.	Blue Lead; Basic Sulfate	840
D 561 – 41.	Carbon Black	842
D 769 – 44 T.	*Black Synthetic Iron Oxide (Tentative)*	1472

Mineral Iron Oxide Pigments

Specifications for:		
D 84 – 43 T.	*Iron Oxide Pigments, Red and Brown (Tentative)*	1474
D 85 – 41.	Ocher	843
D 763 – 44 T.	*Raw Umber (Tentative)*	1476
D 764 – 44 T.	*Burnt Umber (Tentative)*	1477
D 765 – 44 T.	*Raw Sienna (Tentative)*	1478
D 766 – 44 T.	*Burnt Sienna (Tentative)*	1479
D 767 – 44 T.	*Venetian Red (Tentative)*	1480

Blue Pigments

Specifications for:		
†D 261 – 41.	Prussian Blue	845
D 262 – 41.	Ultramarine Blue	847

Green Pigments

Specifications for:		
D 212 – 41.	Chrome Green, Pure	849
†D 213 – 41.	Chrome Green, Reduced	851
†D 263 – 41.	Chrome Oxide Green	853

Yellow and Orange Pigments

Specifications for:		
†D 211 – 43.	Chrome Yellow and Chrome Orange	855
†D 478 – 41.	Zinc Yellow, C. P. (Zinc Chromate)	857
D 768 – 44 T.	*Yellow Iron Oxide, Hydrated (Tentative)*	1482

Red Pigments

Specifications for:		
†D 83 – 41.	Red Lead	859
†D 264 – 41.	Para Red, Reduced	861
†D 475 – 41.	Para Red Toner, C. P.	863
D 656 – 43.	Toluidine Toner, C. P.	865

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.
* Emergency Alternate Provisions applying to this standard have been issued and appear in the pink section of this book, see p. 1172.

For Contents in Numeric Sequence, see p. xxvi.

Metallic Pigments

Specifications for:		PAGE
D 266 – 41.	Aluminum Powder for Paints (Aluminum Bronze Powder)	867
D 474 – 41.	Aluminum Pigment Paste for Paint	869
D 267 – 41.	Gold Bronze Powder	871
D 520 – 41.	Zinc Dust (Metallic Zinc Powder)	873

Miscellaneous

Specifications for:		
D 277 – 31.	Toxic Ingredients in Anti-Fouling Paints (Dry Cuprous Oxide, Dry Mercuric Oxide)	874
†E 11 – 39.	Sieves for Testing Purposes	1146
Methods of:		
†D 278 – 31.	Alkalinity or Acidity of Pigments, Test for	876
†D 279 – 31.	Bleeding of Pigments, Tests for	877
†D 185 – 37.	Coarse Particles in Pigments, Pastes, and Paints, Tests for	879
D 406 – 39.	Hiding Power, Relative Dry, of White Pigments in a Linseed Oil Vehicle, Test for	882
†D 280 – 33.	Hygroscopic Moisture (and Other Matter Volatile Under the Test Conditions) in Pigments, Test for	886
†D 281 – 31.	Oil Absorption of Pigments, Test for	888
†D 153 – 39.	Specific Gravity of Pigments, Test for	889
†D 332 – 36.	Tinting Strength of White Pigments, Test for	896
†D 387 – 36.	Tinting Strength and Mass Color of Color Pigments, Test for	900
D 480 – 44.	Aluminum Powder and Paste, Sampling and Testing of	904
†D 305 – 31.	Dry Lampblack and Dry Bone Black, Test for Acetone Extract	909
D 283 – 39.	Cuprous Oxide, Dry, Chemical Analysis of	910
‡‡C 26 – 42.	Gypsum and Gypsum Products, Testing of	144
†D 284 – 33.	Mercuric Oxide, Dry, Chemical Analysis of	914
†D 49 – 44.	Red Lead, Dry, Chemical Analysis of	917
†D 34 – 39.	White Pigments, Chemical Analysis of	921
†D 126 – 36.	Yellow and Orange Pigments Containing Chromium Compounds, Blue Pigments, and Chrome Green, Chemical Analysis of	934
†D 50 – 36.	Yellow, Orange, Red, and Brown Pigments Containing Iron and Manganese, Chemical Analysis of	944
D 521 – 40.	Zinc Dust (Metallic Zinc Powder), Chemical Analysis of	949
D 444 – 39.	Zinc Yellow Pigment (Zinc Chromate Yellow) Chemical Analysis of	952
D 715 – 43 T.	*Barium Sulfate Pigments, Analysis of (Tentative)*	1484
D 716 – 43 T.	*Mica Pigment, Analysis of (Tentative)*	1488
D 717 – 43 T.	*Magnesium Silicate Pigment, Analysis of (Tentative)*	1491
D 718 – 43 T.	*Aluminum Silicate Pigment, Analysis of (Tentative)*	1494
D 719 – 43 T.	*Diatomaceous Silica Pigment, Analysis of (Tentative)*	1498

Drying Oils and Thinners

Specifications for:		
D 12 – 41.	Tung Oil, Raw	957
D 124 – 41.	Soybean Oil, Raw	959
D 125 – 41.	Perilla Oil, Raw or Refined	960
†D 234 – 28.	Linseed Oil, Raw	961
†D 260 – 33.	Linseed Oil, Boiled	962
D 601 – 41 T.	*Oiticica Oil (Permanently Liquid) (Tentative)*	1500
†D 13 – 34.	Turpentine, Spirits of	963
D 235 – 39.	Petroleum Spirits (Mineral Spirits)	965

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.

For Contents in Numeric Sequence, see p. xxvi.

Definitions of:

D 804 – 44 T. *Tall Oil, Terms Relating to (Tentative)* ... 1532

Lacquer and Lacquer Materials

Specifications for:

D 329 – 33. Acetone ... 1026
D 319 – 40. Amyl Alcohol (Synthetic) ... 1027

† Approved as **American Standard** by the American Standards Association.

[11] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Methods D 29 – 40.

For Contents in Numeric Sequence, see p. xxvi.

Specifications for:

PAGE

D 318 – 39. Amyl Acetate (Synthetic) (85 to 88 per cent Grade)..... 1028
D 554 – 39. Amyl Acetate Made from Fusel Oil (85 to 88 per cent Grade).. 1029
D 361 – 36. Benzene (Benzol), Industrial 90 per cent..... 1030
D 304 – 40. Butanol (Normal Butyl Alcohol)..... 1031
D 303 – 40. Butyl Acetate, Normal (88 to 92 per cent Grade)..... 1032
D 320 – 40. Butyl Propionate (90 to 93 per cent Grade)..... 1033
D 608 – 43. Dibutylphthalate..... 1034
D 302 – 33. Ethyl Acetate (85 to 88 per cent Grade)..... 1035
D 321 – 40. Ethyl Lactate (Synthetic)..... 1036
D 331 – 35. Ethylene Glycol Monoethyl Ether..... 1037
D 343 – 35. Ethylene Glycol Monoethyl Ether, Acetate Ester of (95 to 96 per cent Grade)..... 1038
D 330 – 35. Ethylene Glycol Monobutyl Ether..... 1039
D 657 – 44. Isopropyl Acetate..... 1040
D 770 – 44 T. *Isopropyl Alcohol (Tentative)*..... 1533
D 740 – 43 T. *Methyl Ethyl Ketone (Tentative)*..... 1534
D 362 – 36. Toluene (Toluol), Industrial Pure..... 1041
D 363 – 36. Tricresyl Phosphate..... 1042
D 364 – 36. Xylene (Xylol) or Solvent Naphtha, Industrial..... 1043
D 301 – 33. Nitrocellulose, Soluble..... 1044

Methods of:

D 268 – 44. Lacquer Solvents and Diluents, Sampling and Testing of..... 1053
D 268 – 44 T. *Water in Lacquer Solvents and Diluents, Test for (Tentative)*[12].. 1535
D 522 – 41. Elongation of Attached Lacquer Coatings with the Conical Mandrel Test Apparatus, Test for..... 1063
D 333 – 40. Nitrocellulose Clear Lacquers and Lacquer Enamels, Testing of. 1068
D 365 – 39. Nitrocellulose Base Solutions, Soluble, Testing of..... 1071
D 479 – 40. Reactivity of Paint Liquids, Test for..... 1013
D 609 – 41 T. *Steel Panels for Exposure Tests of Enamels for Exterior Service, Preparation of (Tentative)*..... 1558
D 658 – 44. Abrasion Resistance of Organic Coatings with the Air Blast Abrasion Tester, Test for..... 1105

Definitions of:

D 16 – 44 T. *Paint, Varnish, Lacquer, and Related Products, Terms Relating to (Tentative)*..... 1551

Traffic Paint

Methods of:

D 711 – 43 T. *Dry to No-Pick-Up Time of Traffic Paint, Test for (Tentative)*.. 1538
D 712 – 43 T. *Light Sensitivity of Traffic Paint, Test for (Tentative)*..... 1540
D 713 – 43 T. *Road Service Tests on Traffic Paint, Conducting of (Tentative)*.. 1542

Paint Tests, General

Methods of:

D 215 – 41. Chemical Analysis of White Linseed Oil Paints..... 1075
D 344 – 39. Hiding Power, Relative Dry, of Paints, Test for..... 1092
D 562 – 44. Consistency of Exterior House Paints and Enamel-Type Paints, Test for..... 1095
D 307 – 44. Spectral Characteristics and Color of Objects and Materials, Test for..... 1097
D 523 – 44 T. *Specular Gloss of Paint Finishes, Test for (Tentative)*..... 1544
D 658 – 44. Abrasion Resistance of Organic Coatings with the Air Blast Abrasion Tester, Test for..... 1105
D 771 – 44 T. *Daylight 45 Degree, 0 Degree Apparent Reflectance of Paint Finishes, Test for (Tentative)*..... 1549

[12] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Methods D 268 – 44.

For Contents in Numeric Sequence, see p. xxvi.

Methods of: PAGE

D 38 – 33. Creosote, Sampling and Testing of 788
D 246 – 42. Creosote, Distillation of, Test for 793
D 367 – 33. Creosote, Tests for Insoluble Matter 799
D 368 – 33. Creosote, Specific Gravity of, Test for 801
D 370 – 33. Creosote, Water in, Test for 805
E 28 – 42 T. *Softening Point (Ball and Shouldered Ring Apparatus), Test for (Tentative)* 1580

Definitions of:

D 16 – 44 T. *Paint, Varnish, Lacquer, and Related Products, Terms Relating to (Tentative)* 1551
E 13 – 42. Screen (Sieve), Term 1169
E 12 – 27. Specific Gravity, Terms Relating to 1167

Paint Weathering Tests

Specifications for:

D 358 – 44 T. *Wood to be Used as Panels in Weathering Tests of Paints and Varnishes (Tentative)* 1555

Methods of:

D 609 – 41 T. *Steel Panels for Exposure Tests of Enamels for Exterior Service, Preparation of (Tentative)* 1558
D 610 – 43. Rusting, Evaluating Degree of Resistance to, Obtained with Paint on Iron or Steel Surfaces 1109
D 659 – 44. Chalking, Evaluating Degree of Resistance to, of Exterior Paints of the Linseed-Oil Type 1116
D 660 – 44. Checking, Evaluating Degree of Resistance to, of Exterior Paints of the Linseed-Oil Type 1118
D 661 – 44. Cracking, Evaluating Degree of Resistance to, of Exterior Paints of the Linseed-Oil Type 1121
D 662 – 44. Erosion, Evaluating Degree of Resistance to, of Exterior Paints of the Linseed-Oil Type 1124
D 714 – 43 T. *Blistering, Evaluating Degree of Resistance to, of Organic Coatings on Metal when Subjected to Immersion or Other Tests Involving Exposure to Moisture or Liquids (Tentative)* 1559
D 772 – 44 T. *Flaking (Scaling), Evaluating Degree of Resistance to, of Exterior Paints of the Linseed-Oil Type (Tentative)* 1563
ES – 3. *(Conducting Salt Spray Tests on Organic Protective Coatings) Discontinued.*
B 117 – 44 T. *Salt Spray (Fog) Test (Tentative) (see Part I, p. 1843).*
ES – 35. *Changes in Protective Properties of Organic Coatings on Steel Surfaces When Subjected to Immersion (Emergency Method).* 1189

Recommended Practice for:

E 42 – 42 T. *Carbon Arc Accelerated Weathering Unit, Characteristics of (Tentative)* 1593

Definitions of:

E 41 – 42 T. *Conditioning and Weathering, Terms with Procedures Relating to (Tentative)* 1595

Putty

Specifications for:

D 317 – 33. Putty, Pure Linseed Oil, for Glazing 1127

PLASTICS

Specifications and methods of test for plastics are published in Part III of the Book of A.S.T.M. Standards.

For Contents in Numeric Sequence, see p. xxvi.

THERMOMETERS

Specifications for: PAGE

*E 1 – 44. A.S.T.M. Thermometers 1129
*E 1 – 44 T. A.S.T.M. Thermometers (Tentative)[13] 1567

GENERAL TESTING METHODS

Specifications for:

†E 11 – 39. Sieves for Testing Purposes (Wire Cloth Sieves, Round-Hole and Square-Hole Screens or Sieves) 1146

Methods of:

E 20 – 33 T. *Particle Size Distribution of Subsieve Size Particulate Substances, Test for (Tentative)* 1575
E 28 – 42 T. *Softening Point (Ball and Shouldered Ring Apparatus), Test for (Tentative)* 1580
E 4 – 36. Verification of Testing Machines 1153

Recommended Practices for:

E 29 – 40 T. *Designation of Numerical Requirements in Standards (Tentative)* 1585
E 42 – 42 T. *Carbon Arc Accelerated Weathering Unit, Characteristics of (Tentative)* 1593

Definitions of:

E 6 – 36. Methods of Testing, Terms Relating to 1162
E 12 – 27. Specific Gravity, Terms Relating to 1167
E 13 – 42. Screen (Sieve), Term 1169
E 24 – 42. Rheological Properties of Matter, Terms Relating to 1170
E 41 – 42 T. *Conditioning and Weathering, Terms with Procedures Relating to (Tentative)* 1595

EMERGENCY STANDARDS

Table of Contents of Emergency Standards 1172

EMERGENCY ALTERNATE PROVISIONS

Table of Contents of Emergency Alternate Provisions 1172

List of A.S.T.M. Standing Committees 1611
Index 1613

INSERT PLATE

Plate I. Colors of Treated Sands with Suggested Ranges of Application 438

* Emergency Alternate Provisions applying to this standard have been issued and appear in the pink section of this book, see p. 1172.

† Approved as **American Standard** by the American Standards Association.

[13] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Specifications E 1 – 44.

For Contents in Numeric Sequence, see p. xxvi.

CONTENTS IN NUMERIC SEQUENCE

A.S.T.M. Standards and Tentative Standards Relating to Nonmetallic Materials—Constructional

A complete list in numeric sequence of all A.S.T.M. standards and tentative standards, including titles and page references, appears in the Index to Standards and Tentative Standards furnished annually to A.S.T.M. members and to purchasers of the Book of Standards. This list will be particularly helpful after the appearance of the 1945 and 1946 Supplements since it will contain references to the new and revised standards appearing in the 1945 and 1946 Supplements as well as to those current standards appearing in this book.

STANDARDS AND TENTATIVE STANDARDS

			PAGE
†C	4 – 24.	Spec. for Drain Tile	371
C	5 – 26.	Spec. for Quicklime for Structural Purposes	83
C	6 – 44.	Spec. for Normal Finishing Hydrated Lime	85
C	7 – 42.	Spec. for Paving Brick	169
C	10 – 37.	Spec. for Natural Cement	5
C	11 – 41.	Def. of Terms Relating to Gypsum	158
C	11 – 41 T.	Def. of Terms Relating to Gypsum (Tentative)[1]	1244
C	12 – 19.	Rec. Practice for Laying Sewer Pipe	421
C	13 – 44 T.	Spec. for Standard Strength Clay Sewer Pipe (Tentative)	1316
C	14 – 41.	Spec. for Concrete Sewer Pipe	386
C	16 – 41.	Method of Testing Fireclay Refractories Under Load at High Temperatures	310
C	18 – 41.	Methods of Chemical Analysis of Refractory Materials	271
†C	19 – 41.	Methods of Fire Tests of Building Construction and Materials	234
C	20 – 41.	Methods of Test for Apparent Porosity, Water Absorption, Apparent Specific Gravity, and Bulk Density of Burned Refractory Products	325
†C	22 – 41.	Spec. for Gypsum	122
‡C	24 – 42.	Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials	294
C	25 – 44.	Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime	109
††C	26 – 42.	Methods of Testing Gypsum and Gypsum Products	144
C	27 – 41.	Classification of Fireclay Refractories	269
†C	28 – 40.	Spec. for Gypsum Plasters	124
C	29 – 42.	Method of Test for Unit Weight of Aggregate	449
†C	30 – 37.	Method of Test for Voids in Aggregate for Concrete	451
C	31 – 44.	Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field	466
C	32 – 42.	Spec. for Sewer Brick (Made from Clay or Shale)	176
C	33 – 44.	Spec. for Concrete Aggregates	423
†C	34 – 41.	Spec. for Structural Clay Load-Bearing Wall Tile	187
C	35 – 39.	Spec. for Sand for Use in Plaster	103
†C	36 – 42.	Spec. for Gypsum Wall Board	135
†C	37 – 42.	Spec. for Gypsum Lath	137

† Approved as **American Standard** by the American Standards Association.
‡ A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book, see p. 1601.
[1] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Definitions C 11 – 41.

			PAGE
‡C	38 – 42.	Method of Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick	297
C	39 – 44.	Method of Test for Compressive Strength of Molded Concrete Cylinders	470
C	40 – 33.	Method of Test for Organic Impurities in Sands for Concrete	438
C	42 – 44.	Methods of Securing, Preparing, and Testing Specimens from Hardened Concrete for Compressive and Flexural Strengths	460
C	43 – 36.	Def. of Terms Relating to Structural Clay Tile	200
C	45 – 25.	Spec. for Quicklime and Hydrated Lime for Cooking of Rags in Paper Manufacture	92

C 138 – 44.	Method of Test for Weight per Cubic Foot, Yield, and Air Content (Gravimetric) of Concrete	487
†C 139 – 39.	Spec. for Concrete Masonry Units for Construction of Catch Basins and Manholes	208
†C 140 – 39.	Methods of Sampling andTesting Concrete Masonry Units	210
C 141 – 42.	Spec. for Hydraulic Hydrated Lime for Structural Purposes	87
C 142 – 39.	Method of Test for Clay Lumps in Aggregates	434
C 143 – 39.	Method of Slump Test for Consistency of Portland-Cement Concrete	476
C 144 – 44.	Spec. for Aggregate for Masonry Mortar	232
†C 145 – 40.	Spec. for Solid Load-Bearing Concrete Masonry Units	206
C 146 – 43.	Methods of Chemical Analysis of Glass Sand	332
C 147 – 43.	Method of Hydrostatic Pressure Test on Glass Containers	358
C 148 – 43.	Method of Polariscopic Examination of Glass Containers	362
C 149 – 43.	Method of Thermal Shock Test on Glass Containers	365
C 150 – 44.	Spec. for Portland Cement	1
C 151 – 43.	Method of Test for Autoclave Expansion of Portland Cement	44
†C 152 – 41.	Methods of Fire Tests of Door Assemblies	241
C 153 – 41.	Spec. for Refractories for Moderate Duty Stationary Boiler Service	257
C 154 – 41.	Method of Test for Warpage of Refractory Brick and Tile	324
C 155 – 41 T.	Classification of Insulating Back-Up Block and Insulating Fire Brick (Tentative)	1294
C 156 – 44 T.	Method of Test for Water Retention Efficiency of Methods for Curing Concrete (Tentative)	1351
C 157 – 43.	Method of Test for Volume Change of Cement Mortar and Concrete	483
C 158 – 43.	Method of Flexure Testing of Glass (Determination of Modulus of Rupture)	368
C 159 – 41 T.	Spec. for Vitrified Clay Filter Block for Trickling Filters (Tentative)	1250
C 160 – 41 T.	Method of Test for Fire-Retardant Properties of Wood (Tentative)	1259
C 161 – 44 T.	Spec. for Mortar for Reinforced Brick Masonry (Tentative)	1256
C 162 – 41 T.	Def. of the Term Glass (Tentative)	1315
C 163 – 44.	Methods of Sampling and Mixing Thermal Insulating Cement	246
C 164 – 44.	Method of Test for Bulk Density of Thermal Insulating Cement	248
C 165 – 41 T.	Methods of Test for Compressive Strength and Flexural Strength of Preformed Block Type Thermal Insulating Materials (Tentative)	1279
C 166 – 41 T.	Methods of Test for Covering Capacity and Volume Change Upon Drying of Thermal Insulating Cement (Tentative)	1276
C 167 – 44.	Methods of Test for Thickness and Density of Blanket Type Thermal Insulating Materials	250
C 168 – 44.	Def. of Terms Relating to Thermal Insulating Materials	252
C 169 – 43.	Methods of Chemical Analysis of Soda-Lime Glass	338
C 170 – 41 T.	Method of Test for Compressive Strength of Natural Building Stone (Tentative)	1253
C 171 – 42 T.	Spec. for Waterproof Paper for Curing Concrete (Tentative)	1349
C 172 – 44.	Method of Sampling Fresh Concrete	463
C 173 – 42 T.	Method of Test for Air Content (Volumetric) of Freshly Mixed Concrete (Tentative)	1340
C 174 – 44.	Method of Measuring Length of Drilled Concrete Cores	478
C 175 – 44 T.	Spec. for Air-Entraining Portland Cement for Concrete Pavements (Tentative)	1203
C 176 – 44.	Spec. for Fireclay Plastic Refractories for Boiler and Incinerator Services	265
C 177 – 42 T.	Method of Test for Thermal Conductivity of Materials by Means of the Guarded Hot Plate (Tentative)	1282
C 178 – 44 T.	Spec. for Air-Setting Refractory Mortars (Wet Type) for Boiler and Incinerator Services (Tentative)	1291
C 179 – 43 T.	Method of Test for Combined Drying and Firing Shrinkage of Fireclay Plastic Refractories (Tentative)	1297

† Approved as **American Standard** by the American Standards Association.

C 180 – 43 T.	Method of Panel Test for Resistance to Thermal and Structural Spalling of Fireclay Plastic Refractories (Tentative)	1295
C 181 – 43 T.	Method of Test for Workability Index of Fireclay Plastic Refractories (Tentative)	1299
C 182 – 43 T.	Method of Test for Thermal Conductivity of Insulating Fire Brick (Tentative)	1301
C 183 – 44.	Methods of Sampling Hydraulic Cement	42
C 184 – 44.	Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve	55
C 185 – 44 T.	Method of Test for Air Content of Portland-Cement Mortar (Tentative)	1227
C 186 – 44 T.	Method of Test for Heat of Hydration of Portland Cement (Tentative)	1231
C 187 – 44.	Method of Test for Normal Consistency of Hydraulic Cement	58
C 188 – 44.	Method of Test for Specific Gravity of Hydraulic Cement	64
C 189 – 44.	Method of Test for Soundness of Hydraulic Cement Over Boiling Water (Pat Test)	61
C 190 – 44.	Method of Test for Tensile Strength of Hydraulic-Cement Mortars	70
C 191 – 44.	Methods of Test for Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles	66
C 192 – 44 T.	Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Laboratory (Tentative)	1344
C 193 – 44 T.	Spec. for 85 per cent Magnesia Thermal Insulating Cement (Tentative)	1264
C 194 – 44 T.	Spec. for Asbestos Thermal Insulating Cement (Tentative)	1266
C 195 – 44 T.	Spec. for Mineral Wool Thermal Insulating Cement (Tentative)	1268
C 196 – 44 T.	Spec. for Expanded or Exfoliated Vermiculite Thermal Insulating Cement (Tentative)	1271
C 197 – 44 T.	Spec. for Diatomaceous Silica Thermal Insulating Cement (Tentative)	1274
C 198.	*Not yet assigned.*	
C 199.	*Not yet assigned.*	
C 200 – 44 T.	Spec. for Extra Strength Clay Pipe (Tentative)	1324
D 2 – 33.	Method of Test for Abrasion of Rock by Use of the Deval Machine	513
†D 3 – 18.	Method of Test for Toughness of Rock	514
†D 4 – 42.	Method of Test for Determination of Bitumen	543
†D 5 – 25.	Method of Test for Penetration of Bituminous Materials	573
D 6 – 39 T.	Method of Test for Loss on Heating of Oil and Asphaltic Compounds (Tentative)	1383
D 8 – 33.	Def. of Terms Relating to Materials for Roads and Pavements	611
D 9 – 30.	Def. of Terms Relating to Timber	777
D 12 – 41.	Spec. for Raw Tung Oil	957
†D 13 – 34.	Spec. for Spirits of Turpentine	963
D 16 – 44 T.	Def. of Terms Relating to Paint, Varnish, Lacquer, and Related Products (Tentative)	1551
†D 20 – 30.	Method of Test for Distillation of Tar Products Suitable for Road Treatment	548
†D 25 – 37.	Spec. for Round Timber Piles	704
D 29 – 40.	Methods of Sampling and Analysis of Shellac	993
D 29 – 41 T.	Method of Test for Color of Orange Shellac (Tentative)[6]	1508
†D 34 – 39.	Methods of Chemical Analysis of White Pigments	921
†D 36 – 26.	Method of Test for Softening Point of Bituminous Materials (Ring-and-Ball Method)	578
D 38 – 33.	Methods of Sampling and Testing Creosote	788
D 41 – 41.	Spec. for Primer for Use with Asphalt in Dampproofing and Waterproofing	657
D 43 – 41.	Spec. for Creosote for Priming Coat with Coal-Tar Pitch in Dampproofing and Waterproofing	659
†D 49 – 44.	Methods of Chemical Analysis of Dry Red Lead	917

† Approved as **American Standard** by the American Standards Association.

[6] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Methods D 29 – 40.

EMERGENCY STANDARDS

A List in Numeric Sequence of the Emergency Standards applying to nonmetallic materials—constructional, appears in the pink section on page 1172.

EMERGENCY ALTERNATE PROVISIONS

A List in Numeric Sequence of the Emergency Alternate Provisions applying to nonmetallic materials—constructional, appears in the pink section on page 1172.

* Emergency Alternate Provisions applying to this standard have been issued and appear in the pink section of this book, see p. 1172.
† Approved as **American Standard** by the American Standards Association.
[a] This is in effect a tentative revision of, and, when adopted, is to be added to Standard Specifications E 1 – 44.

Standard Specifications for

PORTLAND CEMENT[1]

A.S.T.M. Designation: C 150 – 44

ADOPTED, 1941; REVISED, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 150; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover five types of portland cement, as follows:

Type I.—For use in general concrete construction when the special properties specified for types II, III, IV, and V are not required.

Type II.—For use in general concrete construction exposed to moderate sulfate action, or where moderate heat of hydration is required.

Type III.—For use when high early strength is required.

Type IV.—For use when a low heat of hydration is required (Note).

Type V.—For use when high sulfate resistance is required (Note).

NOTE.—Attention is called to the fact that cements conforming to the requirements for type IV and type V are not usually carried in stock. In advance of specifying their use, purchasers or their representatives should determine whether these types of cement are, or can be made available.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Prior to adoption as standard, these specifications were published as tentative from 1940 to 1941, being revised in 1941.

These specifications replace the former Standard Specifications for Portland Cement (C 9 – 38), and High-Early-Strength Portland Cement (C 74 – 39), which were accordingly discontinued in September, 1941.

Basis of Purchase

2. The purchaser should specify the type or types desired. When no type is specified, the requirements of type I shall govern.

Definition

3. For the purpose of these specifications, portland cement is the product obtained by pulverizing clinker consisting essentially of hydraulic calcium silicates, to which no additions have been made subsequent to calcination other than water and/or untreated calcium sulfate, except that additions not to exceed 1.0 per cent of other materials may be interground with the clinker at the option of the manufacturer, provided such materials in the amounts indicated have been shown to be not harmful by tests carried out or reviewed by Committee C-1 on Cement[3] (Note).

NOTE.—Tests to determine whether a proposed addition is not harmful will be carried out or reviewed by Committee C-1 on Cement, for

[3] The committee has declared as not harmful the inclusion of the material known commercially as TDA (composed of triethanolamine and highly purified soluble calcium salts of modified lignin sulfonic acids), manufactured by the Dewey and Almy Chemical Co., when added in an amount not exceeding 0.043 per cent by weight of the cement, except that in type III cement a maximum of 0.08 per cent by weight may be used.

those making requests. In the year following that in which an addition has been declared not harmful by the Committee, the name of the addition and the amount permitted shall appear as an addendum to Section 3 in a revision of the specifications.

Chemical Requirements

4. Portland cement of each of the five types shown in Section 1 shall conform to the respective chemical requirements prescribed in Table I.

TABLE I.—CHEMICAL REQUIREMENTS.

	Type I	Type II	Type III	Type IV[a]	Type V[a]
Silicon dioxide (SiO_2), min., per cent	...	21.0	...	...	24.0
Aluminum oxide (Al_2O_3), max., per cent	...	6.0	...	...	4.0
Ferric oxide (Fe_2O_3), max., per cent	...	6.0	...	6.5	4.0
Magnesium oxide (MgO), max., per cent	5.0	5.0	5.0	5.0	4.0
Sulfur trioxide (SO_3), max., per cent	2.0	2.0	2.5	2.0	2.0
Loss on ignition, max., per cent	3.0	3.0	3.0	2.3	3.0
Insoluble residue, max., per cent	0.75	0.75	0.75	0.75	0.75
Ratio of Al_2O_3 to Fe_2O_3	...	0.7 to 2.0	...	...	0.7 to 2.0
Tricalcium silicate ($3CaO \cdot SiO_2$),[b] max., per cent	...	50	...	35	...
Dicalcium silicate ($2CaO \cdot SiO_2$),[b] min., per cent	...	...	...	40	...
Tricalcium aluminate ($3CaO \cdot Al_2O_3$),[b] max., per cent	...	8	15	7	5

[a] See Note, Section 1.

[b] The expressing of chemical limitations by means of calculated assumed compounds does not necessarily mean that the oxides are actually or entirely present as such compounds.

The percentages of tricalcium silicate, dicalcium silicate, and tricalcium aluminate shall be calculated from the chemical analysis as follows:

Tricalcium silicate =
(4.07 × per cent CaO) − (7.60 × per cent SiO_2)
− (6.72 × per cent Al_2O_3) − (1.43 × per cent Fe_2O_3) − (2.85 × per cent SO_3)

Dicalcium silicate =
(2.87 × per cent SiO_2) − (0.754 × per cent $3CaO \cdot SiO_2$)

Tricalcium aluminate =
(2.65 × per cent Al_2O_3) − (1.69 × per cent Fe_2O_3)

Oxide determinations calculated to the nearest 0.1 per cent shall be used in the calculations. Compound percentages shall be calculated to the nearest 0.1 per cent and reported to the nearest 1 per cent.

Physical Requirements

5. Portland cement of each of the five types shown in Section 1 shall conform to the respective physical requirements prescribed in Table II.

Packaging and Marking

6. When cement is delivered in packages, the name and brand of the manufacturer and the type under these specifications shall be plainly indicated thereon, except that in the case of type I the type need not be indicated. Similar information shall be provided in the shipping advices accompanying the shipment of packaged or bulk cement. A bag shall contain 94 lb. net. A barrel shall consist of 376 lb. net. All packages shall be in good condition at the time of inspection.

Storage

7. The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the cement from dampness and minimize warehouse set.

Inspection

8. Every facility shall be provided the purchaser for careful sampling and inspection, either at the mill or at the site of the work, as may be specified by the purchaser. The following periods from time of sampling shall be allowed for completion of testing:

1-day test	6 days
3-day test	8 days
7-day test	12 days
28-day test	33 days

Rejection

9. (*a*) The cement may be rejected if it fails to meet any of the requirements of these specifications.

(*b*) Cement remaining in bulk storage

at the mill, prior to shipment, for a period greater than 6 months after completion of the tests may be retested and may be rejected if it fails to conform to any of the requirements of these specifications.

(*c*) Packages varying more than 5 per cent from the specified weight may be rejected; and if the average weight of packages in any shipment, as shown by weighing 50 packages taken at random, is less than that specified, the entire shipment may be rejected.

TABLE II.—PHYSICAL REQUIREMENTS.

	Type I	Type II	Type III	Type IV[a]	Type V[a]
Fineness, specific surface, sq. cm. per g.:					
Average value, min.	1600	1700	...	1800	1800
Minimum value, any one sample	1500	1600	...	1700	1700
Soundness:					
Autoclave expansion, max., per cent	0.50	0.50	0.50	0.50	0.50
Time of setting (alternate methods):[b]					
Gillmore test:					
Initial set, min., not less than	60	60	60	60	60
Final set, hr., not more than	10	10	10	10	10
Vicat test:					
Initial set, min., not less than	45	45	45	45	45
Final set, hr., not more than	10	10	10	10	10
Compressive strength, psi.:[c] The compressive strength of mortar cubes, composed of 1 part cement and 2.75 parts graded standard sand, by weight, prepared and tested in accordance with Method C 109, shall be equal to or higher than the values specified for the ages indicated below:					
1 day in moist air	...	...	1250	...	...
1 day in moist air, 2 days in water	900	750	2500	...	...
1 day in moist air, 6 days in water	1800	1500	...	800	1000
1 day in moist air, 27 days in water	3000	3000	[c]	2000	2200
Tensile strength, psi.:[c] The tensile strength of mortar briquets composed of 1 part cement and 3 parts standard sand, by weight, prepared and tested in accordance with Method C 190, shall be equal to or higher than the values specified for the ages indicated below:					
1 day in moist air	...	...	275	...	...
1 day in moist air, 2 days in water	150	125	375	...	...
1 day in moist air, 6 days in water	275	250	...	175	175
1 day in moist air, 27 days in water	350	325	[c]	300	300

[a] See Note, Section 1.

[b] The purchaser should specify the type of setting time test required. In case he does not so specify, the requirement of the Gillmore test only shall govern.

[c] The purchaser should specify the type of strength test required. In case he does not so specify, the requirements of the tensile strength test only shall govern. The strength at any age shall be higher than the strength at the next preceding age. Unless otherwise specified, the compressive and tensile strength tests for types I and II cement will be made only at 3 and 7 days. If, at the option of the purchaser, a 28-day test is required on type III cement, the strength at 28 days shall be higher than at 3 days.

Methods of Testing

10. The cement shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Standard Methods of Sampling Hydraulic Cement (A.S.T.M. Designation: C 183).[4]

(*b*) *Chemical Analysis.*—Standard Methods of Chemical Analysis of Portland Cement (A.S.T.M. Designation: C 114 - 44)[4] and Tentative Methods of Chemical Analysis of Portland Cement (A.S.T.M. Designation: C 114 - 44 T).[4]

(*c*) *Fineness.*—Standard Method of Test for Fineness of Portland Cement by the Turbidimeter (A.S.T.M. Designation: C 115).[4]

(*d*) *Autoclave Expansion.*—Standard

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Method of Test for Autoclave Expansion of Portland Cement (A.S.T.M. Designation: C 151).[4]

(*e*) *Time of Setting.*—Standard Methods of Test for Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles (A.S.T.M. Designation: C 191).[4]

(*f*) *Compressive Strength.*—Standard Method of Test for Compressive Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 109).[4]

(*g*) *Tensile Strength.*—Standard Method of Test for Tensile Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 190).[4]

Standard Specifications for
NATURAL CEMENT[1]

A.S.T.M. Designation: C 10 – 37

ADOPTED, 1904; REVISED, 1908, 1909, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 10; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover natural cement.

Definition

2. Natural cement is the product obtained by finely pulverizing calcined argillaceous limestone, to which not to exceed 5 per cent of nondeleterious materials may be added subsequent to calcination. The temperature of calcination shall be no higher than is necessary to drive off carbonic acid gas.

Fineness

3. The residue on a standard No. 200 (74-micron) sieve shall not exceed 15 per cent by weight.

Soundness

4. A pat of neat cement, about 3 in. in diameter, and 0.5 in. in thickness at the center and tapering to a thin edge, shall be kept in moist air for a period of 48 hr. The pat shall then be placed in an atmosphere of steam at a temperature between 98 and 100 C. on a suitable support 1 in. above boiling water for 5 hr. and shall show no signs of distortion, cracking, checking, or disintegration upon removal from the steam chest.

Time of Setting

5. The cement shall not develop initial set in less than 10 min. when the Vicat needle is used or in less than 20 min. when the Gillmore needle is used. Final set shall be attained within 10 hr.

Tensile Strength

6. (*a*) The average tensile strength of not less than three standard mortar briquets (see Section 11) composed of one part of cement and two parts of standard sand, by weight, shall be equal to or higher than the following:

AGE AT TEST, DAYS	STORAGE OF SPECIMENS	TENSILE STRENGTH, PSI.
7	1 day in moist air, 6 days in water....	75
28	1 day in moist air, 27 days in water...	150

(*b*) The average tensile strength of standard mortar at 28 days shall be higher than the strength at 7 days.

Packages and Marking

7. The cement shall be delivered in packages as specified with the brand and

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Editorially revised in 1939.

name of the manufacturer plainly marked thereon, unless shipped in bulk. When shipped in bulk, this information shall be contained in the shipping advices accompanying the shipment. A barrel shall contain 282 lb. net. All packages shall be in good condition at the time of inspection.

Storage

8. The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building which will protect the cement from dampness.

Inspection

9. Every facility shall be provided the purchaser for careful sampling and inspection either at the mill or at the site of the work, as may be specified by the purchaser. At least 12 days from the time of sampling shall be allowed for completion of the 7-day test and at least 33 days shall be allowed for completion of the 28-day test.

Rejection

10. (*a*) The cement may be rejected if it fails to conform to any of the requirements of these specifications.

(*b*) Cement remaining in storage prior to shipment for a period greater than 6 months after completion of the tests shall be retested and shall be rejected if it fails to conform to any of the requirements of these specifications.

(*c*) Cement shall not be rejected on account of failure to conform to the fineness requirement if upon retest after drying at 100 C. for 1 hr. it meets this requirement.

(*d*) Cement failing to meet the test for soundness in steam may be accepted if it passes a retest using a new sample at any time within 28 days thereafter. The provisional acceptance of the cement at the mill shall not deprive the purchaser of the right of rejection on a retest of soundness and time of setting at the time of delivery of cement to the purchaser.

Methods of Testing[3]

11. The cement shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials, except as otherwise prescribed in these specifications:

(*a*) *Sampling.*—Standard Methods of Sampling Hydraulic Cement (A.S.T.M. Designation: C 183).[4]

(*b*) *Fineness.*—Standard Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve (A.S.T.M. Designation: C 184).[4]

(*c*) *Soundness.*—Standard Method of Test for Soundness of Hydraulic Cement Over Boiling Water (Pat Test) (A.S.T.M. Designation: C 189),[4] except that immediately after being made the pat shall be stored in moist air for 48 hr. and then placed in an atmosphere of steam at a temperature between 98 and 100 C. on a suitable support 1 in. above boiling water for 5 hr.

(*d*) *Time of Setting.*—Standard Methods of Test for Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles (A.S.T.M. Designation: C 191).[4]

(*e*) *Tensile Strength.*—Standard Method of Test for Tensile Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 190),[4] except that the proportions of the standard mortar shall be one part of cement to two parts of standard sand, by weight.

---

[3] This section was editorially revised in 1944.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

MASONRY CEMENT[1]

A.S.T.M. Designation: C 91 – 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 91; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover cement to be used in conjunction with sand in the making of mortar for laying units of masonry construction.

Time of Setting

2. Neat cement paste mixed to normal consistency shall not develop initial set in less than 60 min. as determined by the Gillmore needle. Final set shall be attained within 24 hr.

Soundness

3. A pat of neat cement shall remain firm and hard, and show no signs of distortion, cracking, checking, or disintegration in the steam test for soundness.

Compressive Strength

4. The average compressive strength of not less than three 2-in. cubes, made, stored, and tested in accordance with Sections 19 to 25, shall be not less than 350 psi. at the age of 7 days. The average strength at 28 days shall be not less than 600 psi.

Water Retention

5. Cement mortar after suction for 60 sec. shall have a flow greater than 65 per cent of that immediately after mixing, when tested in accordance with the procedure described in Section 26.

Staining

6. This requirement shall apply only when the invitation for bids specifically states that the cement shall be nonstaining to limestone. Nonstaining cement shall contain not more than 0.03 per cent of water-soluble "alkali" when tested in accordance with Section 27.

NOTE.—The amount and nature of the staining material in limestones seem to vary with the stone. The alkali in any cement may, therefore, induce markedly different staining on different stone, even though the stone may have come apparently from the same source. The amount of alkali permitted by the specifications should not cause stain unless stone high in staining material has been used, or unless insufficient means have been used to prevent infiltration of water into the masonry.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Prior to adoption as standard, these specifications were published as tentative from 1932 to 1940, being revised in 1938 and 1940. Editorially revised in 1944.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

Packaging and Marking

7. The cement shall be delivered in suitable bags or barrels with the brand and name of the manufacturer and the net weight plainly marked thereon. All packages shall be in good condition at the time of inspection. Packages varying more than 5 per cent from the weight marked thereon may be rejected, and if the average weight of packages in any shipment as shown by weighing 50 packages taken at random is less than the weight marked thereon, the entire lot represented may be rejected.

Storage

8. The cement shall be stored in a suitable weathertight building that will protect it from dampness, and in such a manner as to permit safe and easy access for proper inspection and identification of each lot.

Inspection

9. Every facility shall be provided the purchaser for the necessary inspection and sampling.

Rejection

10. The cement shall be rejected if it fails to meet any of the requirements of these specifications. Cement remaining in storage prior to shipment for a period greater than 6 months after test shall be retested, and shall be rejected if it fails to meet any of the requirements of these specifications.

SAMPLING AND METHODS OF TESTING

Size and Number of Samples

11. Each sample of cement selected for purpose of tests shall weigh at least 5 lb. and shall represent not more than 300 bbl. If only one sample is taken, it shall weigh at least 10 lb.

Shipment of Samples

12. Samples shall be shipped and stored in airtight, moistureproof containers.

Temperature

13. The temperature of the room and dry materials shall be maintained at not less than 20 C. (68 F.) and not more than 27.5 C. (81.5 F.). The temperature of the mixing water, moist closet, and water in the briquet storage tank shall not vary from 21 C. (70 F.) by more than 1.7 C (3 F.).

Preparation of Samples

14. The sample of cement shall be given a preliminary sieving by being passed through a No. 20 (840-micron) sieve[3] in order to thoroughly mix the sample, break up lumps, and remove foreign materials.

Mixing

15. (*a*) *Pastes.*—A 500-g. portion of the cement shall be placed in the form of a crater on a plane, nonabsorbent plate. About one half of the necessary mixing water shall be poured into the crater, the cement mixed into the water with the finger tips until all the water is taken up by the cement, the remainder of the water added, and the paste then mixed with the fingers until all the water is absorbed. The mixing operation shall then be completed by continuously and vigorously squeezing and kneading the paste with the hands for at least 3 min. During the operation of mixing, the hands shall be protected by rubber gloves.

(*b*) *Mortars.*—The mortars shall be mixed in a nonabsorbent bowl of about 1-gal. capacity. A measured quantity

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

of water shall be poured into the bowl which has previously been wiped with a damp cloth. A 500-g. portion of the cement shall then be added and stirred into the water with the fingers of one hand until all the cement is wetted. Approximately 800 g. of sand shall then be added and the stirring continued for 30 sec. The remainder of 1500 g. of sand shall then be added and the mortar mixed for 75 sec. by vigorous and continued stirring, squeezing, and kneading with one hand. The mortar shall then be allowed to stand for 60 sec. and then mixed for another 60 sec. During the operation of mixing, the hands shall be protected by rubber gloves.

Normal Consistency[4]

16. Normal consistency shall be determined by the Vicat apparatus in accordance with the Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187),[5] except that the mixing of the paste shall be performed in accordance with Section 15 (*a*) of these specifications.

Time of Setting Test[4]

17. The time of setting shall be determined by the Gillmore needle method in accordance with the Standard Methods of Test for Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles (A.S.T.M. Designation: C 191),[5] except that the mixing of the paste shall be performed in accordance with Section 15 (*a*) of these specifications.

Soundness Test[4]

18. Pats of neat cement, made and tested in accordance with the Standard Method of Test for Soundness of Hydraulic Cement over Boiling Water (Pat Test) (A.S.T.M. Designation: C 189),[5] except that the pastes shall be prepared in accordance with Section 15 (*a*) of these specifications, shall remain firm and hard and show no signs of distortion, checking, cracking, or disintegration.

Compressive Strength Test

19. *Molds* (*a*).—The compression test specimens shall be 2-in. cubes. Molds for the specimens shall be tight fitting. The parts of the molds, when assembled, shall be positively held together. The molds shall be made of hard metal not attacked by the cement mortar. For new molds, the Rockwell hardness number of the metal shall be not less than B55 (the Brinell hardness number not less than 95). There shall be sufficient material in the sides of the molds to prevent spreading or warping.

(*b*) The interior faces of the molds shall be true plane surfaces with a permissible variation of 0.001 in. for new molds and 0.002 in. for molds in use.

(*c*) The distances between opposite faces of the molds shall be 2 ± 0.005 in. for new molds, or 2 ± 0.01 in. for molds in use. The height of the molds, measured separately for each cube compartment, shall be 2 in. with a permissible variation of plus 0.01 in. and minus 0.005 in. for new molds, or plus 0.01 in. and minus 0.015 in. for molds in use.

(*d*) The angle between adjacent interior faces and between interior faces and top and bottom planes of the mold shall be 90 ± 0.5 deg.

(*e*) Molds shall be oiled with a mineral oil before using.

20. *Standard Sand.*[6]—The sand used for making test specimens shall be natural silica sand from Ottawa, Ill., graded to pass a No. 20 (840-micron) sieve and retained on a No. 30 (590-micron)

[4] This section was editorially revised in 1944.

[5] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[6] This section was added editorially in 1944.

sieve.[3] This sand shall be considered standard when not more than 15 g. are retained on the No. 20 sieve, and not more than 5 g. pass the No. 30 sieve after 5 min. of continuous sieving of a 100-g. sample in the manner specified for sieving cement in the Standard Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve (A.S.T.M. Designation: C 184).[5]

21. (*a*) *Proportions for Standard Mortar.*[4]—The mortar shall consist of 1 part of cement to 3 parts of standard sand by weight.

(*b*) *Preparation of Standard Mortar.*—The mortar shall be mixed with a measured quantity of water in accordance with the procedure described in Section 15 (*b*). The top of the flow table (Paragraph (*c*)) shall be carefully wiped dry and the flow mold placed at the center and filled with mortar. In filling the mold, the mortar shall not be rammed, but gently smoothed off level with the top of the mold by aid of a trowel and the mold then removed. Immediately, the table shall be dropped through a height of $\frac{1}{2}$ in., 25 times in 15 sec. The flow is the resulting increase in diameter of the mortar mass, expressed as a percentage of the original diameter. The mortar shall be of standard consistency when the flow is 65 to 80 per cent. Trial mortars shall be made with varying percentages of water until the standard consistency is obtained. Each trial shall be made with fresh mortar. The quantity of water shall be expressed as a percentage of the weight of the combined dry materials.

(*c*) *Flow Table.*—The flow table apparatus consists of a rigid frame with a flat circular top, so mounted on a vertical shaft that it can be raised and dropped through a fixed height of $\frac{1}{2} \pm \frac{1}{32}$ in. by means of a rotated cam. The top shall be of noncorrodible metal 10 in. in diameter and with the attached shaft shall weigh 9 lb. $\pm$ 1 oz. The frame shall be attached rigidly to a concrete pedestal, which in turn shall be attached rigidly to the floor. The concrete pedestal shall be at least 8 in. in diameter and 25 in. in height and shall weigh at least 100 lb. The mold shall be of a noncorrodible material, 4 in. in inside diameter at the base, $2\frac{3}{4}$ in. at the top, and 2 in. in height.

22. *Molding of Test Cubes.*—Immediately after mixing the standard mortar in accordance with the procedure described in Sections 15 and 21, the mortar shall be placed in the cube molds which shall rest on plane, nonabsorbent plates. The molds shall be filled heaping full without compacting. Then the mortar shall be gently worked into the molds with the thumbs, using only sufficient effort to insure uniform filling of the molds. Additional mortar shall be heaped above the molds and smoothed off with a trowel. The molds and plates shall then be turned over upon plane, nonabsorbent plates oiled with mineral oil, the first plates removed, and the operation of heaping, thumbing, and smoothing off repeated. No ramming or tamping shall be used, nor any troweling in excess of that required to smooth off the specimens.

23. *Storage of Test Cubes.*—All test specimens, immediately after molding, shall be kept in the molds on plane plates in a damp closet, maintained at a relative humidity of 90 per cent or more, for from 48 to 52 hr. in such a manner that the upper surfaces shall be exposed to the moist air. The cubes shall then be removed from the molds and placed in the damp closet for 5 days in such a manner as to allow free circulation of air around at least five faces of the specimens. At the age of 7 days the cubes for the 28-day tests shall be immersed in clean running

water in storage tanks of noncorrodible materials.

24. *Testing of Cubes* (*a*).—The testing machine for determination of the compressive strength may be of either the hydraulic or the screw-type with sufficient opening between the upper bearing surface and the lower bearing surface of the machine to permit the use of verifying apparatus. The load applied to the test specimen shall be indicated with an accuracy of plus or minus 1.0 per cent.

(*b*) The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to turn in any direction. The diagonal or diameter of the bearing surface shall be only slightly greater than the diagonal of the face of the 2-in. cube, in order to facilitate accurate centering of the specimen. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower plate of the machine. The bearing block surface intended for contact with the specimen should have a hardness not less than Rockwell number C60 (Brinell number 620). These surfaces shall not depart from plane surfaces by more than 0.0005 in. when the blocks are new, and shall be maintained within a permissible variation of 0.001 in.

(*c*) Testing of the cube specimens shall be carried out immediately upon their removal from the moist closet for 7-day specimens, and from storage water for all other specimens. If more than one specimen at a time is removed from the storage water for testing, these cubes shall be placed in a pan of water of sufficient depth to completely immerse each cube until its removal for testing. The load shall be applied to the faces of the cubes that were in contact with the true plane surfaces of the mold. These faces shall be checked by application of an accurate straightedge. If appreciable curvature is present, the face or faces shall be ground to a plane surface before loading, or the specimens shall be discarded.

(*d*) Loose sand grains or incrustations shall be removed from the contact faces, and the cubes shall then be carefully placed in the testing machine below the center of the upper bearing block. No cushioning or bedding materials shall be used. The loading up to 25 per cent of the expected maximum load may be applied at any convenient rate, after which the specimens shall be loaded continuously to failure at a rate or rates which shall at no time be less than 1000 nor more than 6000 psi. per min.

25. *Calculations.*—The total maximum load indicated by the testing machine shall be recorded, and the compressive strength calculated in pounds per square inch from the cross-sectional area of the cube tested. Cubes that are manifestly faulty or that give strengths differing by more than 10 per cent from the average value of all test specimens made from the same sample and tested at the same period shall not be considered in determining the compressive strength.

Water Retention Test

26. (*a*) *Apparatus.*—For the water retention test, an apparatus essentially the same as that shown in Fig. 1 shall be used. This apparatus consists of a water aspirator controlled by a mercury column relief and connected by way of a three-way stopcock to a funnel upon which rests a perforated dish. A mercury manometer, connected as shown in

Fig. 1, indicates the vacuum. A rubber gasket shall be sealed to the top of the funnel and shall be kept wet during a test to insure a seal between the funnel and dish. The perforated dish shall be made of nonabsorbent material. Hardened filter paper equivalent to Carl

diately after making the flow test, the mortar on the flow table shall be remixed for 30 sec. with that remaining in the mixing bowl. Immediately after remixing, the mortar shall be uniformly distributed without compacting over the sheet of dampened filter paper in

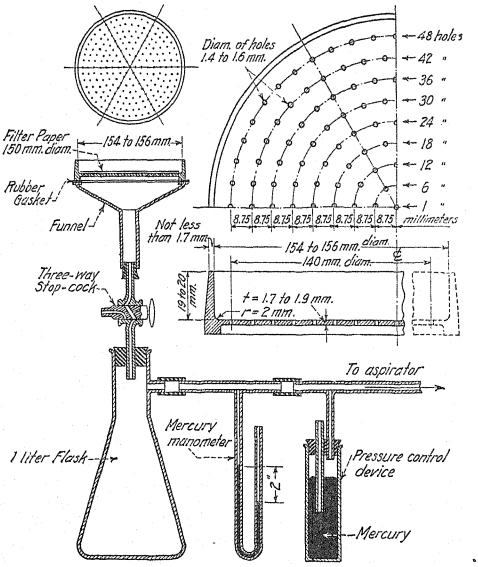

FIG. 1.—Apparatus Assembly for the Water Retention Test.

Schleicher and Schull filter paper No. 575 shall be used. It shall be of such diameter that it will lie flat and completely cover the bottom of the dish.

(*b*) *Method.*—The mortar shall be mixed to a flow of from 100 to 115 per cent in accordance with the procedure described in Section 21. Immediately after making the flow test, the mortar on the flow table shall be remixed for 30 sec. with that remaining in the mixing bowl. Immediately after remixing, the mortar shall be uniformly distributed without compacting over the sheet of dampened filter paper in the perforated dish and the surface leveled off flush with the rim of the dish by drawing a straightedge across the dish with a slightly sawing motion. The dish shall then be seated on the wetted gasket, and with the mercury column set at 2 in., the stopcock shall be turned to apply the vacuum to the

funnel. After suction for 60 sec., the stopcock shall be quickly turned to expose the funnel to atmospheric pressure. The contents of the dish shall then be immediately removed by means of a putty knife or square-end spatula and placed in the mold on the flow table. As each portion of mortar is placed in the mold it shall be well puddled with glove-covered fingers. When the mold is filled, the mortar shall be smoothed off level with the top of the mold, using the edge of a trowel, and the flow determined as previously. The entire operation shall be carried out without interruption and as quickly as possible and shall not require more than 7 min. for completion, starting from the completion of the mixing of the mortar for the first flow determination. Both flow determinations shall be made in accordance with the procedure described in Section 21 (*b*), special care being taken to fill the mold uniformly when obtaining the flow after suction.

Staining Test (Determination of Water-Soluble Alkali)

27. Water-soluble alkali shall be determined in accordance with Section 20 of the Standard Methods of Chemical Analysis of Portland Cement (A.S.T.M. Designation: C 114).[5]

Standard Methods of

CHEMICAL ANALYSIS OF PORTLAND CEMENT[1]

A.S.T.M. Designation: C 114 - 44

ADOPTED 1939; REVISED 1940, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 114; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods outline procedures for the chemical analysis of portland cement. The procedures appear in the following order:

	Section
Silicon Dioxide	8
Aluminum Oxide and Ferric Oxide	9
Ferric Oxide	10 and 11
Aluminum Oxide	12
Calcium Oxide	13
Magnesium Oxide	14 and 15
Sulfur Trioxide	16
Loss on Ignition	17
Sodium Oxide and Potassium Oxide	18 and 19
Water-Soluble Alkali	20
Phosphorus Pentoxide	21 and 22
Manganic Oxide	23 and 24
Insoluble Residue	25
Chloroform-Soluble Organic Substances	26 and 27
Free Calcium Oxide	28 and 29
Silicon Dioxide, Alternate Method	30
Calcium Oxide, Alternate Method	31 and 32
Magnesium Oxide:	
Alternate Method A	33
Alternate Method B	34 and 35
Alternate Method C	36 and 37
Phosphorus Pentoxide, Alternate Method	38 and 39
Manganic Oxide, Alternate Method	40 and 41
Free Calcium Oxide, Alternate Method	42 and 43
Recommended Order for Reporting Analysis	44

Sampling

2. Samples of the cement shall be taken and prepared as prescribed in the Standard Methods of Sampling Hydraulic Cement (A.S.T.M. Designation: C 183).[3]

Apparatus

3. (*a*) *Balances.*[4]—The analytical balances used in the chemical determinations shall conform to the following requirements:

Capacity not less than 100 g. in each pan,

The two arms of the beam equal within (*1*) two parts in 100,000 for balances in use or (*2*) one part in 100,000 for new balances (Note 1),

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] These methods of chemical analysis were editorially rearranged and issued under the designation C 114 in 1939. They formerly constituted a portion of the Standard Methods of Sampling and Testing Portland Cement (A.S.T.M. Designation: C 77) and were published as standard in Methods C 77 from 1930 to 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book

[4] Information on Analytical Balances and Weights, to supplement the requirements for balances and weights prescribed in these methods, has been prepared and is published as information, not a part of these methods; see the compilation of "A.S.T.M. Standards on Cement," issued as a separate publication.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book

Capable of reproducing results within 0.0002 g., and

Sensibility reciprocal[5] not more than 0.0005 g. per division of the graduated scale for any load up to 100 g. (Note 2). In case of direct-reading balances this requirement does not apply.

Any rapid weighing device that may be provided, such as a chain, damped motion, or heavy riders, shall not introduce errors greater than 0.0001 g. at any reading and with any allowable load on the scale pans.

NOTE 1.—The lengths and ratios of the arms may change with use, and with age even if not used.

NOTE 2.—If an auxiliary metal or glass pan is used, its weight is a part of the load.

(*b*) *Weights.*[4]—The weights used in the chemical determinations shall conform to the requirements of the National Bureau of Standards specifications for class "S" weights as prescribed in Bureau of Standards *Circular No. 3*, "Design and Test of Standards of Mass." The weights (including the riders) shall be checked when questioned, or at least once a year, with weights that have been certified by the National Bureau of Standards within five years. They shall be adjusted within the tolerances given in the above mentioned specifications for class "S" weights, according to their apparent mass as determined by comparison with brass standards in air.

Purity of Water and Reagents

4. (*a*) *Water.*—References to water shall be understood to mean distilled water.

(*b*) *Reagents.*—Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[6] Where such specifications are not available, the best grade available should be used. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

Concentration of Reagents

5. (*a*) *Concentrated Acids and Ammonium Hydroxide.*—When acids and ammonium hydroxide are specified by name or chemical formula only, it shall be understood that concentrated reagents of the following specific gravities or concentrations are intended:

Hydrochloric acid, HCl	sp. gr. 1.18
Hydrofluoric acid, HF	48 per cent
Nitric acid, HNO_3	sp. gr. 1.42
Sulfuric acid, H_2SO_4	sp. gr. 1.84
Ammonium hydroxide, NH_4OH	sp. gr. 0.90

The desired specific gravities or concentrations of all other concentrated acids shall be stated whenever they are specified.

(*b*) *Diluted Acids and Ammonium Hydroxide.*—Concentrations of diluted acids and ammonium hydroxide, except when standardized, shall be specified as a ratio stating the number of volumes of the concentrated reagent to be diluted with a given number of volumes of water, as in the following example: HCl (1:99) means 1 volume of concentrated HCl (sp. gr. 1.18) diluted with 99 volumes of water.

---

[5] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

[6] "A.C.S. Analytical Reagents," American Chemical Society, Washington, D. C., March, 1941. For later additions and revisions, see "Recommended Specifications for Analytical Reagent Chemicals" by the Committee on Analytical Reagents of the American Chemical Society, *Industrial and Engineering Chemistry*, Analytical Edition, Vol. 16, No. 5, May, 1944, p. 281. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards" by Joseph Rosin, D. Van Nostrand Co., Inc., New York, N. Y., (1937).

(*c*) *Standard Solutions.*—Concentrations of standard solutions shall be expressed as normalities or as equivalents in grams per milliliter of the component to be determined, for example: 0.1 *N* $Na_2S_2O_3$, or $K_2Cr_2O_7$ (1 ml. = 0.004 g. Fe_2O_3).

(*d*) *Nonstandardized Solutions.*—Concentrations of nonstandardized solutions prepared by dissolving a given weight of the solid reagent in a solvent shall be specified in grams of the reagent per liter of solution, and it shall be understood that water is the solvent unless otherwise specified, for example: NaOH (10 g. per l.) means 10 g. of NaOH dissolved in water and diluted with water to 1 liter. In the case of certain reagents the concentration may be specified as a percentage by weight, for example: ethanol (50 per cent) means a solution containing 50 g. of ethanol per 100 g. of solution. Other nonstandardized solutions may be specified by name only, and the concentration of such solutions will be governed by the instructions for their preparation.

Glassware[7]

6. (*a*) All glass apparatus and vessels used in analytical work should be carefully selected to meet the particular requirements for each operation. Standard volumetric flasks, burettes, and pipettes should be of precision grade.

(*b*) New and improved types of glass apparatus are available, including colored glass for the protection of solutions affected by light, alkali-resistant glass for use where superior resistance to alkalies is important, and a high-silica glass having exceptional resistance to thermal shock. Standard-taper, interchangeable, ground-glass joints are useful in analytical work.

Number of Chemical Determinations

7. (*a*) The number of chemical tests shall be as prescribed in Section 6 of the Standard Methods of Sampling Hydraulic Cement (A.S.T.M. Designation: C 183).[3]

(*b*) The chemical determinations shall be made in accordance with the procedures described in the following Sections 8 to 43.

NOTE.—These methods of chemical analysis are not all considered as possessing the highest obtainable accuracy, but are methods to be followed in making acceptance tests on cements covered by specifications requiring that tests be made in accordance with the analytical procedures contained in this standard.

SILICON DIOXIDE

Procedure

8. (*a*) Transfer 0.5 g. of the sample to an evaporating dish, preferably of platinum for the sake of celerity in evaporation, moisten with 10 ml. of cold water to prevent lumping, add 5 to 10 ml. of HCl, and digest with the aid of gentle heat and agitation until solution is complete. Solution may be aided by light pressure with the flattened end of a glass rod. Evaporate the solution to dryness on a steam bath. Without heating the residue any further, treat it with 5 to 10 ml. of HCl and then an equal amount of water, or pour at once upon the residue 10 to 20 ml. of HCl (1:1). Then cover the dish and digest for 10 min. on the bath or a hot plate. Dilute the solution with an equal volume of hot water, immediately filter, and wash the separated

[7] For further information the following references may be consulted:

SiO_2 thoroughly with hot water (Note), and reserve the residue.

NOTE.—The washing of the SiO_2 precipitates can be made more effective by using hot HCl (1:99) and then completing the washing with hot water.

(*b*) Again evaporate the filtrate to dryness, baking the residue in an oven for 1 hr. at 105 to 110 C. Then take up the residue with 10 to 15 ml. of HCl (1:1) and heat on the bath or hot plate. Dilute the solution with an equal volume of hot water and catch and wash the small amount of SiO_2 it contains on another filter paper. Reserve the filtrate and washings for the determination of $Al_2O_3 + Fe_2O_3$ (Section 9).

(*c*) Transfer the papers containing the residues (Paragraphs (*a*) and (*b*)) to a weighed platinum crucible. Dry and ignite the papers, first at a low heat until the carbon of the filter paper is completely consumed without inflaming, and finally at 1100 to 1200 C. until the weight remains constant.

(*d*) Treat the SiO_2 thus obtained, which will contain small amounts of impurities, in the crucible with a few drops of water, about 10 ml. of HF, and one drop of H_2SO_4, and evaporate cautiously to dryness. Finally, heat the small residue at 1050 to 1100 C. for a minute or two, cool, and weigh. The difference between this weight and the weight previously obtained represents the amount of SiO_2. Consider the weighed residue remaining after the volatilization of the SiO_2 as combined aluminum and ferric oxides and add it to the result obtained in the determination of these oxides (Section 9).

(*e*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*f*) *Calculation.*—Calculate the percentage of SiO_2 to the nearest 0.1 by multiplying the weight in grams of SiO_2 by 200, (100 divided by the weight of sample used (0.5 g.)).

ALUMINUM OXIDE AND FERRIC OXIDE

Procedure

9. (*a*) To the filtrate reserved in accordance with Section 8 (*b*) (Note 1), which should have a volume of about 250 ml., add HCl if necessary to insure a total of 10 to 15 ml. of the acid. Add a few drops of methyl red indicator (2 g. per liter of ethanol), and heat to boiling. Then treat with NH_4OH (Note 2), drop by drop, until one drop changes the color of the solution to a distinct yellow. Bring to boiling the solution containing the precipitated aluminum and ferric hydroxides, boil for 1 or 2 min., and then filter. Wash the precipitate once by decantation and wash slightly on the filter with hot NH_4Cl (20 g. per l.).

NOTE 1.—If a platinum evaporating dish has been used for the dehydration of SiO_2, iron may have been partially reduced. At this stage, add about 3 ml. of saturated bromine water to the filtrate and boil the filtrate to eliminate the excess bromine before adding the methyl red indicator.

NOTE 2.—The NH_4OH used to precipitate the hydroxides must be free of contamination with CO_2.

(*b*) Set aside the filtrate and transfer the precipitate and filter paper to the same beaker in which the first precipitation was effected. Dissolve the aluminum and ferric hydroxides in hot HCl (1:3), dilute the solution to about 100 ml., and reprecipitate the hydroxides as described in Paragraph (*a*). Filter the solution, and wash the precipitate with two 10-ml. portions of hot NH_4Cl (20 g. per l.). Combine the filtrate and washings with the filtrate set aside and reserve for the determination of CaO (Section 13).

(*c*) Place the precipitate in a weighed platinum crucible, heat slowly until the papers are charred, and finally ignite to constant weight at 1050 to 1100 C. with care to prevent reduction, and weigh as $Al_2O_3 + Fe_2O_3$.

(*d*) Add to the weight of $Al_2O_3 + Fe_2O_3$ any impurities that may be found in the residue of SiO_2 according to Section 8 (*d*). If a determination of phosphorus pentoxide is required and made according to Section 22, the weight of $Al_2O_3 + Fe_2O_3$ shall be corrected for the amount of P_2O_5 found.

(*e*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*f*) *Calculation.*—Calculate the percentage of $Al_2O_3 + Fe_2O_3$ to the nearest 0.1 by multiplying the weight in grams of $Al_2O_3 + Fe_2O_3$ by 200, (100 divided by the weight of sample used (0.5 g.)).

FERRIC OXIDE

Reagents

10. (*a*) *Stannous Chloride Solution.*—Dissolve 10 g. of $SnCl_2 \cdot 2H_2O$ in 25 ml. of HCl and 75 ml. of water. Add scraps of iron-free granulated tin and boil until the solution is clear. Keep the solution in a closed dropping bottle containing metallic tin.

(*b*) *Phosphoric-Sulfuric Acid Mixture.*—Add slowly, while stirring, 150 ml. of H_3PO_4 (sp. gr. 1.71) and 150 ml. of H_2SO_4 to 500 ml. of water, and then dilute to 1 liter and mix.

(*c*) *Diphenylamine Indicator.*—Dissolve 1 g. of diphenylamine in 100 ml. of H_2SO_4.

(*d*) *Standard Potassium Dichromate Solution* (*1 ml. = 0.004 g. Fe_2O_3*).—Dissolve 2.457 g. of $K_2Cr_2O_7$ in water and dilute to 1 liter. Standardize against standard iron wire of known iron content in the same manner as directed for the ferric oxide determination in cement (Section 11), using a weight of iron wire that will yield a titration approximately equal to that required by the cement sample in question. Calculate the Fe_2O_3 equivalent of the solution in grams per milliliter by multiplying the weight in grams of iron in the amount of iron wire used by 1.430 (molecular ratio of Fe_2O_3 to 2 Fe) and dividing by the volume in milliliters of $K_2Cr_2O_7$ solution required.

Procedure

11. (*a*) To 1 g. of the sample add 40 ml. of cold water, stir, and add 15 ml. of HCl. Heat the solution, and grind the cement with the flattened end of a glass rod until it is evident that the cement is completely decomposed. Heat the solution to boiling and treat it with the $SnCl_2$ solution, added drop by drop while stirring, until the solution is decolorized. Add one drop in excess and cool the solution to room temperature. Rinse the inside of the vessel with water, and add all at once 10 ml. of a cool, saturated $HgCl_2$ solution. Stir the solution vigorously for 1 min., add 15 ml. of H_3PO_4 - H_2SO_4 mixture and 3 drops of diphenylamine indicator, and dilute to 150 ml. with cold water. Titrate with the standard $K_2Cr_2O_7$ solution. The end point is taken as the point at which a drop causes an intense deep blue coloration that remains unchanged on further addition of the standard $K_2Cr_2O_7$ solution.

(*b*) *Calculation.*—Calculate the percentage of Fe_2O_3 to the nearest 0.1 as follows:

$$Fe_2O_3, \text{ per cent} = EV \times 100$$

where:

E = Fe_2O_3 equivalent of the $K_2Cr_2O_7$ solution in grams per milliliter, and

V = milliliters of $K_2Cr_2O_7$ solution required by the 1-g. sample used.

ALUMINUM OXIDE

Procedure

12. *Calculation.*—Calculate the percentage of Al_2O_3 to the nearest 0.1 by deducting the percentage of Fe_2O_3 determined according to Section 11 from the percentage of $Al_2O_3 + Fe_2O_3$ determined according to Section 9.

NOTE.—Any titanium and phosphorus that may be present will be precipitated with aluminum and ferric hydroxides in the procedure specified in Section 9 and are counted as Al_2O_3. Aluminum oxide should not be corrected for TiO_2 or P_2O_5 unless such a correction is expressly specified or the determination of the component is required. If the precipitations of the hydroxides are made as directed, little manganese, if any, will be retained in the precipitate.

CALCIUM OXIDE

Procedure

13. (*a*) Acidify the combined filtrates obtained in the precipitations of aluminum and ferric hydroxides (Section 9) with HCl and evaporate them to a volume of about 100 ml. Add 40 ml. of saturated bromine water to the hot solution and immediately add NH_4OH until the solution is distinctly alkaline. Boil the solution for 5 min. or more, making certain that the solution is at all times distinctly alkaline. Allow the precipitate to settle, filter, and wash with hot water. Wash the beaker and filter once with HNO_3 (1:33) that has been previously boiled to expel nitrous acid, and finally with hot water. Discard the precipitate. Acidify the filtrate with HCl and boil until all the bromine is expelled. Make the solution alkaline with NH_4OH and bring the solution to boiling. Add to the boiling solution 25 ml. of boiling ammonium oxalate (50 g. per l.), the boiling being continued until the precipitated calcium oxalate assumes a well-defined granular form. Allow the solution to stand for about 20 min. or until the precipitate has settled, filter, and wash moderately with ammonium oxalate (1 g. per l.). Reserve the filtrate and washings.

(*b*) Place the filter paper containing the precipitate, wet, in a platinum crucible and burn off the paper at a low heat. Then ignite the precipitate until the calcium oxalate is converted to CaO, redissolve (Note 1) in HCl, and dilute the solution to 100 ml. with water. Add NH_4OH in slight excess and bring the solution to boiling. If a small amount of hydroxides separates at this point, filter it out, weigh, and add the amount to that found in the original determination of $Al_2O_3 + Fe_2O_3$. Reprecipitate the CaO with ammonium oxalate as before (Note 2), allow to stand until settled, filter, and wash, taking care to avoid an excess of the washing solution. Combine the filtrate with that already obtained and reserve for the determination of MgO (Section 15).

NOTE 1.—Add 5 ml. of cold water cautiously to the first ignited precipitate and then cautiously add 10 ml. of HCl (1:1). As soft-burnt calcium oxide may be too active in slaking, a temperature of 1100 to 1200 C. is recommended for the ignition of the first precipitate. After a little practice it is possible to dissolve hard-burnt calcium oxide in this way without explosive spattering.

NOTE 2.—If the second precipitate of calcium oxalate is so fine as to cause difficulty in filtering, or if the precipitate causes bumping, the volume of solution may be increased to 150 or 200 ml., instead of 100 ml., prior to precipitation.

(*c*) Weigh the precipitate as CaO, after ignition and heating at 1100 to 1200 C. to constant weight in a weighed, covered platinum crucible.

(*d*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*e*) *Calculation.*—Calculate the percentage of CaO to the nearest 0.1 by multiplying the weight in grams of CaO by 200, (100 divided by the weight of sample used (0.5 g.)).

MAGNESIUM OXIDE

Reagents

14. *Ammonium Nitrate Wash Solution.*—Dissolve 100 g. of NH_4NO_3 in water, add 200 ml. of NH_4OH, and dilute to 1 liter.

Procedure

15. (*a*) Acidify the filtrates reserved in the determination of CaO (Section 13) with HCl and concentrate to about 150 ml. Add to this solution about 10 ml. of $(NH_4)_2HPO_4$ (250 g. per l.) and cool the solution by placing in a beaker of ice water. After cooling, add NH_4OH drop by drop, while stirring constantly, until the crystalline magnesium ammonium phosphate begins to form, and then in moderate excess (5 to 10 per cent of the volume of the solution), the stirring being continued for several minutes. Set the solution aside for at least 8 hr. in a cool atmosphere, and then filter.

(*b*) Redissolve the precipitate thus obtained in hot HCl (1:4), dilute the solution to about 100 ml., add 1 ml. of $(NH_4)_2HPO_4$ (250 g. per l.), and then add NH_4OH drop by drop, while stirring constantly, until the precipitate is again formed as described and the NH_4OH is in moderate excess. Cool, allow to stand for about 2 hr., filter, and wash with two 10-ml. portions of the NH_4NO_3 wash solution. Place in a weighed platinum crucible, slowly char the paper, and carefully burn off the resulting carbon. Ignite the precipitate at 1100 to 1200 C. to constant weight, taking care to avoid bringing the pyrophosphate to melting.

(*c*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*d*) *Calculation.*—Calculate the percentage of MgO to the nearest 0.1 as follows:

$$\text{MgO, per cent} = W \times 72.4$$

where:

W = grams of $Mg_2P_2O_7$, and
72.4 = molecular ratio of 2 MgO to $Mg_2P_2O_7$ (0.362) divided by weight of sample used (0.5 g.) and multiplied by 100.

SULFUR TRIOXIDE

Procedure

16. (*a*) To 1 g. of the sample add 25 ml. of cold water and 5 ml. of HCl. Heat the solution and grind the material with the flattened end of a glass rod until it is evident that decomposition of the cement is complete. Dilute the solution to 50 ml. and digest on a steam bath for 15 min. Filter, and wash the residue thoroughly with hot water. Dilute the solution to 250 ml. and heat to boiling. Add slowly, drop by drop from a pipette, 10 ml. of hot $BaCl_2$ (100 g. per l.) and continue the boiling until the precipitate is well formed. Digest the solution on the steam bath for at least 3 hr., preferably overnight. Filter the precipitate, wash, place the paper and contents in a weighed platinum crucible, and slowly char and consume the paper without inflaming. Then ignite and weigh the $BaSO_4$.

(*b*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*c*) *Calculation.*—Calculate the percentage of SO_3 to the nearest 0.1 as follows:

$$\text{SO}_3\text{, per cent} = W \times 34.3$$

where:

W = grams of $BaSO_4$, and
34.3 = molecular ratio of SO_3 to $BaSO_4$ (0.343) multiplied by 100.

(*d*) *Optional Procedure.*—The acid filtrate obtained in the determination of

the insoluble residue (Section 25) may be used for the determination of SO_3 instead of using a separate sample.

LOSS ON IGNITION

Procedure

17. (*a*) Heat 1 g. of the sample in a weighed, covered platinum crucible of 20 to 25-ml. capacity, as follows, using either method A or B as specified.

(*b*) *Method A.*—Place the crucible in a hole in an asbestos board clamped horizontally, so that about three fifths of the crucible projects below the board, and heat at a full red heat (900 to 1000 C.) for 15 min.; check the loss in weight by a second heating for 5 min. Take care to wipe off particles of asbestos that may adhere to the crucible when withdrawn from the hole in the board. Greater neatness and shortening of the time of heating may be secured by making a hole to fit the crucible in a circular disk of sheet platinum and placing this disk over a somewhat larger hole in an asbestos board.

(*c*) *Method B.*—Place the crucible in a muffle furnace at any temperature between 900 and 1000 C. for 15 min., and check the loss in weight by a second heating for 5 min.

(*d*) *Calculation.*—Calculate the percentage of loss on ignition to the nearest 0.1 by multiplying the loss in weight in grams by 100.

SODIUM OXIDE AND POTASSIUM OXIDE

Reagents

18. (*a*) *Chloroplatinic Acid Solution (50 g. per l.).*—Dissolve 5 g. of $H_2PtCl_6 \cdot 6H_2O$ in water and dilute to 100 ml.

(*b*) *Gladding Wash Solution.*—Dissolve 100 g. of NH_4Cl in water, dilute to 500 ml., and add to the solution an amount of K_2PtCl_6 that is more than sufficient to make a saturated solution (about 1 g.). Shake the mixture frequently for 6 to 8 hr., allow it to stand at least 12 hr., and filter. The residue may be used for the preparation of a new supply of the wash solution.

Procedure

19. (*a*) Weigh 5 g. of the sample of finely pulverized cement and mix it with 1 g. of NH_4Cl by grinding the two together in an agate mortar. Add 4 g. of $CaCO_3$ to the mixture and continue the grinding until the ingredients are thoroughly mixed. Place about 0.5 cm. of $CaCO_3$ on the bottom of a 40 to 60-ml. platinum crucible, add the above mixture to the crucible, and cover the mixture with about 0.5 cm. of $CaCO_3$. Mount the crucible through a hole in an asbestos board about 0.3 cm. in thickness, so that the crucible projects about 1 cm. above the board. Cover the crucible with a well-fitting cover and set a platinum crucible containing water on it. The purpose of the second crucible is to prevent the loss of alkali by volatilization, and this crucible must be kept filled with water through the entire period of ignition. Heat the crucible at a very low temperature at first and gradually raise the temperature within 1 hr. to a bright red heat. At no time should the temperature be raised so fast that white NH_4Cl fumes can be seen issuing from the crucible. Finally, ignite the crucible at 900 to 1000 C. for 1 hr.

(*b*) With the aid of hot water, remove the sintered material from the crucible and let the sinter digest with about 150 ml. of water in a casserole on a water bath for about 4 hr. If there are still lumps in the casserole, break them up with a pestle or glass rod. Allow the mixture to digest on the water bath 4 hr. more, or longer. Boil the mixture for 1 min., allow the residue to settle, and decant the clear solution through a

filter paper into a large beaker. Add 30 ml. of water to the casserole, bring the mixture to a boil, allow the residue to settle, and decant the clear filtrate through the same filter paper (Note). Perform three more times this addition of water and decantation. Finally, wash the residue into the filter paper, rinse the casserole, and wash the residue once with hot water.

NOTE.—If it is desired to speed up the work without allowing the residue to settle so as to give a clear solution to decant easily, filter the solution at once, leaving as much of the residue in the dish as possible, discharge the filtrate held in the stem of the funnel by tapping the funnel or lifting the filter paper a little out of the funnel, and wash the residue on the filter paper back into the dish.

(*c*) Combine the filtrates and washings and evaporate them to about 50 ml. Add 3 or 4 g. of $(NH_4)_2CO_3$ to the solution, and boil it for 1 min. Filter the solution, and wash the residue six times with cool $(NH_4)_2CO_3$ (10 g. per l.) that contains a little NH_4OH. Add 10 ml. of ammonium oxalate (50 g. per l.) and 2 or 3 ml. of NH_4OH to the filtrate. Evaporate the solution to about 20 ml., filter into a dish, and wash the residue with hot water. Add 1 ml. of H_2SO_4 to the filtrate and evaporate it to dryness.

(*d*) Ignite the residue in the dish carefully until the excess H_2SO_4 is driven off and then raise the temperature to a dull red heat. Cool the dish, dissolve the residue in 50 ml. of water, and add 2 ml. of ammonium oxalate (50 g. per l.) and 2 or 3 ml. of NH_4OH to the solution. Evaporate the solution to about 10 ml., filter the solution into a platinum dish, and wash the residue with hot water. Add 0.5 ml. of H_2SO_4 to the filtrate and evaporate it to dryness. Ignite the residue, gradually raising the temperature to 600 to 700 C., until all the excess H_2SO_4 and ammonium salts are expelled. Cool the dish, dissolve the residue in a small amount of water, evaporate the solution to dryness, ignite the residue at 600 to 700 C. for 15 min., cool it in a desiccator, and weigh. Dissolve the residue in about 20 ml. of hot water and filter the solution. Wash the filter paper with hot water and put it in the dish. Ignite carefully until the paper is consumed and then continue the ignition at 600 to 700 C. for 10 min. Cool the dish in a desiccator, and weigh. The difference between these two weights represents the weight of the alkali as Na_2SO_4 and K_2SO_4.

(*e*) Add 1 to 2 ml. of HCl to the filtrate in a vessel made of glass, silica, or porcelain and evaporate it to about 10 ml. To the solution, add 6 ml. of the solution of chloroplatinic acid for each 0.10 g. of the mixed sulfates and add 3 ml. in excess. Evaporate the solution on a water bath to a thick sirup, carrying this evaporation as far as possible without allowing the solution to go to dryness. The sirupy solution should solidify on cooling. Add 100 ml. of ethanol (85 per cent) to the solution, while stirring thoroughly, and allow the precipitate of potassium chloroplatinate (K_2PtCl_6) to settle for just 3 hr. Filter the clear liquid through a dried and tared Gooch crucible with a mat of asbestos or a fused-in fritted-glass disk. Wash the precipitate five times by decantation with ethanol (85 per cent) and then rinse the crucible three times with the ethanol. Wash the precipitate three times by decantation with the Gladding wash solution, stirring the precipitate thoroughly each time. Transfer the precipitate to the crucible with the Gladding wash solution, taking care that none remains in the original vessel, and finally wash the crucible and contents six times with ethanol (85 per cent). Dry the crucible at 105 to 110 C. for at least 3 hr. Cool, and weigh it. The difference between

these two weights represents the weight of K_2O as K_2PtCl_6.

(*f*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*g*) *Calculation.*—Calculate the percentages of Na_2O and K_2O to the nearest 0.01 as follows:

$$Na_2O, \text{ per cent} = (W_1 - W_2 \times 0.3584) \times 8.728, \text{ and}$$

$$K_2O, \text{ per cent} = W_2 \times 3.874$$

where:

W_1 = grams of $Na_2SO_4 + K_2SO_4$,
W_2 = grams of K_2PtCl_6,
0.3584 = molecular ratio of K_2SO_4 to K_2PtCl_6,
8.728 = molecular ratio of Na_2O to Na_2SO_4 (0.4364) divided by the weight of sample used (5 g.) and multiplied by 100, and
3.874 = molecular ratio of K_2O to K_2PtCl_6 (0.1937) divided by the weight of sample used (5 g.) and multiplied by 100.

WATER-SOLUBLE ALKALI[8]

NOTE.—The determination of water-soluble alkali according to Section 20 should not be considered as a substitute for the determination of total alkali according to Section 19. Moreover, it is not to be assumed that in the procedure of Section 20 all water-soluble alkali is obtained that may be in the cement. A uniform method is essential where there is a specified limit on the content of water-soluble alkali or where several lots of cement are compared on the basis of water-soluble alkali.

Procedure

20. (*a*) Weigh 25 to 150 g. of the sample (Note 1) into a large beaker and add 250 ml. of water to the cement, while stirring thoroughly (Note 2). Let the mixture stand for 30 min. at room temperature, stir it again, and filter it through a Büchner funnel. Return the residue to the original beaker, rinse the funnel with 150 ml. of water into the beaker, stir the mixture thoroughly, and let it stand 30 min. at room temperature. Again stir the solution and filter it through the Büchner funnel. Return the residue to the beaker and rinse the funnel with 100 ml. of water into the beaker. Stir the mixture thoroughly, and let it stand 30 min. at room temperature. Stir it and filter it as before, discard the residue without washing, and complete the determination as described in either Paragraphs (*b*) to (*d*) or Paragraph (*e*) (Note 3).

NOTE 1.—The amount of sample taken for analysis depends on the content of water-soluble alkali, varying from 25 g. for 0.5 per cent or more to 150 g. for 0.1 per cent or less.

NOTE 2.—As the amount of water-soluble alkali obtained depends on the manner in which it is leached out of cement, it is important that the procedure be followed closely.

NOTE 3.—In most cases the procedure described in Paragraphs (*b*) to (*d*) is to be preferred because it is simpler and usually gives all the data necessary.

(*b*) Follow the procedure as described in Section 19 (*c*) and (*d*).

(*c*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*d*) *Calculation.*—Calculate as Na_2O the percentage of water-soluble alkali to the nearest 0.01 as follows:

$$Na_2O, \text{ per cent} = \frac{W \times 43.64}{S}$$

where:

W = grams of $Na_2SO_4 + K_2SO_4$,
S = grams of sample used, and

[8] The procedure for determining water-soluble alkali as described in Section 20 is identical in substance with Section F-3b of the Federal Specification for Masonry Cement (SS-C-181b, January 12, 1938) in regard to leaching of cement. The differences in the treatment of the combined filtrates should not produce an appreciable difference in the results.

43.64 = molecular ratio of Na_2O to Na_2SO_4 (0.4364) multiplied by 100.

(*e*) If it is required that water-soluble alkali be reported as water-soluble Na_2O and water-soluble K_2O, follow the procedure as described in Section 19, starting with Paragraph (*c*) and making the necessary changes in the formulas of Paragraph (*g*) due to the weight of sample taken for analysis. If desired, a measured portion of the combined filtrates may be taken for the steps following the leaching in order to avoid the use of a large amount of chloroplatinic acid.

PHOSPHORUS PENTOXIDE

Reagents

21. (*a*) *Ammonium Molybdate Solution.*—Dissolve 100 g. of molybdic acid (85 per cent MoO_3) in a mixture of 400 ml. of water and 100 ml. of NH_4OH and cool the solution to room temperature. While stirring constantly, pour this solution very slowly into a cooled mixture of 600 ml. of water and 400 ml. of HNO_3. No precipitate should form that does not redissolve upon stirring. Add 1 drop of $(NH_4)_2HPO_4$ (250 g. per l.) to the solution, shake it thoroughly, and allow it to stand at least 24 hr. before use. Filter portions of the solution as needed.

(*b*) *Magnesia Mixture.*—Dissolve 50 g. of $MgCl_2 \cdot 6H_2O$ and 100 g. of NH_4Cl in 500 ml. of water. Make the solution slightly alkaline with NH_4OH and allow it to stand at least 12 hr. Filter the solution, acidify it with HCl, and dilute to 1 liter.

Procedure

22. (*a*) Weigh 1 to 3 g. of the sample (Note) and 10 g. of NH_4NO_3 into a 150-ml. beaker. Mix the contents, treat with 10 ml. of HNO_3, and stir quickly, using the flattened end of a glass rod to crush lumps of cement, until the cement is completely decomposed and the thick gel of SiO_2 is broken up. Cover the beaker with a watch glass, place it on a water bath or a hot plate at approximately 100 C. for 15 to 20 min., and stir the contents occasionally during the heating. Add 20 ml. of hot water to the beaker and stir the contents. If the cement contains an appreciable amount of manganese, as shown by the presence of a red or brown residue, add a few milliliters of $NaNO_2$ (50 g. per l.) to dissolve this residue. Boil the contents of the beaker until all nitrous fumes are completely expelled. This should not take more than 5 min., and water should be added to replace any lost by evaporation. Filter into a 500-ml. Erlenmeyer flask under suction and with a platinum cone to support the filter paper, and wash the residue of SiO_2 until the volume of filtrate and washings is about 150 ml.

NOTE.—The amounts of sample and reagents used depend on the content of phosphorus in the cement. The minimum requirements are sufficient if the cement contains 0.5 per cent P_2O_5 or more. The maximum amounts are required if the content of P_2O_5 is 0.1 per cent or less.

(*b*) Heat the solution to 85 C. and add 50 to 100 ml. of the ammonium molybdate solution. Stopper the flask and shake it vigorously for 5 min., then set aside for 30 min. Filter the precipitate, rinsing the flask five times and washing the filter paper eight times with cold KNO_3 (10 g. per l.). Put the original flask under the funnel containing the precipitate. Pour 25 ml. of NH_4OH (1:4) over the precipitate and around the upper edges of the filter paper until the precipitate is entirely dissolved. Wash the paper three times with cold water, twice with HCl (1:1), and finally three times with cold water. Acidify the solution with HCl and add to it 1 ml. of citric acid (350 g. per l.) to hold traces of iron, if any, in solution.

(*c*) Cool the solution to room temperature and transfer it to a 400-ml. beaker. The volume should now be about 150 ml. Add 25 ml. of the magnesia mixture to the solution, and then, while stirring constantly, add drop by drop 50 ml. of NH_4OH at such a rate that 5 min. are required for the addition. Allow the mixture to stand 4 hr. or longer. Filter the precipitate, and wash it a few times with NH_4OH (1:20). Dissolve the precipitate into the original beaker by pouring 25 ml. of HCl (1:1) on the precipitate. Wash the filter paper thoroughly with HCl (1:20). With the washings and water, dilute the solution to 50 to 100 ml., and add 1 to 2 ml. of the magnesia mixture. While stirring constantly, add NH_4OH slowly to the solution as before. Allow the mixture to stand 2 hr. or longer. Filter the precipitate, scrub and rinse the beaker, and wash the precipitate ten times with NH_4OH (1:20). Ignite the precipitate in a weighed crucible at 1100 to 1200 C. to constant weight.

(*d*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*e*) *Calculation.*—Calculate the percentage of P_2O_5 to the nearest 0.01 as follows:

$$P_2O_5, \text{ per cent} = \frac{W \times 63.79}{S}$$

where:

W = grams of $Mg_2P_2O_7$,
S = grams of sample used, and
63.79 = molecular ratio of P_2O_5 to $Mg_2P_2O_7$ (0.6379) multiplied by 100.

MANGANIC OXIDE

Reagent

23. *Standard Sodium Arsenite Solution (1 ml. = 0.0003 g. Mn_2O_3).*—Dissolve in 100 ml. of water 3.0 g. of Na_2CO_3 and then 0.90 g. of As_2O_3, heating the mixture until the solution is as complete as possible. If the solution is not clear or contains a residue, filter the solution. Cool it to room temperature, transfer to a volumetric flask, and dilute to 1 liter.

Dissolve 0.58 g. of $KMnO_4$ in 1 liter of water and standardize it against about 0.03 g. of sodium oxalate oxidimetric standard furnished by the National Bureau of Standards (standard sample No. 40) according to the directions furnished with the sodium oxalate. Put 30.0 ml. of the $KMnO_4$ solution in a 250-ml. Erlenmeyer flask. Add 60 ml. of HNO_3 (1:4) and 10 ml. of $NaNO_2$ (50 g. per l.) to the flask. Boil the solution until the HNO_2 is completely expelled. Cool the solution and add sodium bismuthate ($NaBiO_3$), and finish by titrating with the standard $NaAsO_2$ solution in the manner described below for the determination of manganese in cement. Calculate the Mn_2O_3 equivalent of the $NaAsO_2$ solution in grams per milliliter as follows:

$$E = \frac{A \times 7.08}{BC}$$

where:

E = Mn_2O_3 equivalent of the $NaAsO_2$ solution in grams per milliliter,
A = grams of $Na_2C_2O_4$,
B = milliliters of $KMnO_4$ solution required by the $Na_2C_2O_4$ used,
C = milliliters of $NaAsO_2$ solution required by 30.0 ml. of $KMnO_4$ solution, and
7.08 = molecular ratio of Mn_2O_3 to 5 $Na_2C_2O_4$ (0.236) multiplied by 30.0 (milliliters of $KMnO_4$ solution).

Procedure

24. (*a*) Weigh 1.0 to 3.0 g. of the sample (Note 1) into a 250-ml. beaker

and treat it with 5 to 10 ml. of water and then with 60 to 75 ml. of HNO_3 (1:4). Boil the mixture until the solution is as complete as possible. Add 10 ml. of $NaNO_2$ (50 g. per l.) to the solution and boil it until the HNO_2 is completely expelled (Note 2), taking care not to allow the volume of the solution to become so small as to cause the precipitation of gelatinous SiO_2. There may be some separated SiO_2, which may be ignored, but if there is still a red or brown residue, use more $NaNO_2$ (50 g. per l.) to effect a complete decomposition and then boil again to expel the HNO_2. Filter the solution into a 250-ml. Erlenmeyer flask and wash the filter paper with water.

NOTE 1.—The amount of cement taken for analysis depends on the content of manganese, varying from 1 g. for about 1 per cent of Mn_2O_3 to 3 g. for 0.25 per cent or less of Mn_2O_3.

NOTE 2.—When $NaNO_2$ is added, the expulsion of HNO_2 by boiling must be complete. If any HNO_2 remains in the solution, it will react with the added $NaBiO_3$ and decrease its oxidizing value. If there is any manganese in the cement, the first small quantity of $NaBiO_3$ should bring out a purple color.

(*b*) The solution should have a volume of 100 to 125 ml. Cool it to room temperature. To the solution add a total of 0.5 g. of $NaBiO_3$ in small quantities, while shaking intermittently. After the addition is completed, shake the solution occasionally for 5 min. and then add to it 50 ml. of cool HNO_3 (1:33) which has been previously boiled to expel nitrous acid. Filter the solution through a pad of ignited asbestos in a Gooch crucible or a carbon or fritted-glass filter with the aid of suction. Wash the residue four times with the cool HNO_3 (1:33). Titrate the filtrate immediately with the standard solution of As_2O_3. The end point is reached when a yellow color is obtained free of brown or purple tints and it does not change upon further addition of As_2O_3.

(*c*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*d*) *Calculation.*—Calculate the percentage of Mn_2O_3 to the nearest 0.01 as follows:

$$Mn_2O_3, \text{ per cent} = \frac{EV}{S} \times 100$$

where:

E = Mn_2O_3 equivalent of the $NaAsO_2$ solution in grams per milliliter,
V = milliliters of $NaAsO_2$ solution required by the sample, and
S = grams of sample used.

INSOLUBLE RESIDUE[9]

Procedure

25. (*a*) To 1 g. of the sample, add 10 ml. of cold water and 5 ml. of HCl. Warm the solution gently and grind the material with the flattened end of a glass rod for a few minutes until it is evident that decomposition of the cement is complete (Note). Dilute the solution to 50 ml. and digest for 15 min. at a temperature just short of boiling. Filter the residue, wash six times with hot water, and digest the filter paper and contents in 100 ml. of NaOH (10 g. per l.), the solution being held at a temperature just short of boiling for 15 min. Using methyl red as indicator, acidify the solution with HCl and add an excess equivalent to 4 or 5 drops of HCl. Filter and wash the residue 12 to 15 times with hot NH_4Cl (20 g. per l.).

[9] This method or any other method designed for the estimation of acid-insoluble substance in any type of cement is empirical, because the amount obtained depends on the reagents and the time and temperature of digestion. If the amount is large, there may be a little variation in duplicate determinations. The directions should be followed closely in order to reduce the variation to a minimum. When the method is used on blended cement, the decomposition in acid is considered to be complete when the portland cement clinker is decomposed completely. An NH_4Cl solution is used in the final washing to prevent finely ground insoluble material from passing through the filter paper.

Ignite the residue in a tared crucible at 900 to 1000 C., cool it in a desiccator, and weigh.

NOTE.—If a sample of portland cement contains an appreciable amount of manganic oxide, there may be brown compounds of manganese which dissolve slowly in cold diluted HCl but rapidly in hot HCl in the specified strength. In all cases, dilute the solution as soon as decomposition is complete.

(*b*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*c*) *Calculation.*—Calculate the percentage of insoluble residue to the nearest 0.01 by multiplying the gain in weight in grams by 100.

CHLOROFORM-SOLUBLE ORGANIC SUBSTANCES[10]

Reagent

26. *Chloroform.*—If the blank determination as described in Section 27 (*e*) exceeds 0.0015 g., the chloroform should be distilled before use. Chloroform recovered in the procedure may be slightly acid but can be reused for the portions to be shaken with the aqueous acid solution of the sample in the 1-liter funnel. Chloroform used for washing the filter and transferring the extract should be fresh or distilled from fresh chloroform.

Procedure

27. (*a*) Place 40 g. of cement in a large beaker and mix it with 520 ml. of water, starting with a small portion of the water and stirring the slurry until it is free of lumps and is of a uniform, thick consistency before adding the balance of the water. While stirring the slurry to a uniform suspension, add rapidly 185 ml. of HCl in which 10 g. of $SnCl_2 \cdot 2H_2O$ have been dissolved, and continue the stirring. When the cement is completely decomposed, cool the solution rapidly to room temperature by immersion in cold water, while stirring occasionally. Transfer the solution to a 1-liter Squibb separatory funnel (Note 1) and rinse the beaker with a little water. Add 75 ml. of chloroform to the solution, rinsing the beaker with the chloroform in three portions as it is added. Stopper the funnel, shake it vigorously for 5 min., and allow the water and chloroform to stand 15 min. to separate.

NOTE 1.—The use of grease to lubricate the stopcocks and glass stoppers of the separatory funnels should be avoided. Wetting the stopcocks with water before using will assist in their easy operation.

(*b*) Draw off the lower chloroform layer into a 125-ml. Squibb separatory funnel, including the scum (Note 2) with a few milliliters of the aqueous solution, making certain that all the scum is transferred. Keep the amount of the aqueous layer transferred to an absolute minimum, since excessive water in the 125-ml. funnel may result in incomplete extraction of the scum and may cause an emulsion which does not separate readily. Shake the funnel vigorously to insure the complete extraction of the scum. Allow the chloroform to separate, and draw it into a 250-ml. Squibb separatory funnel which contains 50 ml. of water and a few drops of HCl, making sure to keep the scum behind in the 125-ml. funnel. Shake the 250-ml. funnel, and draw the chloroform into another 250-ml. funnel that contains 50 ml. of water and a few drops of HCl. Shake this funnel as in the case of the

[10] This method was specially designed for the determination of Vinsol resin and tallow in portland cement, although mineral oil, common rosin, calcium stearate, and other fatty acid compounds, and probably some other substances, if present, will be included in the determination. With all the apparatus set up, an experienced operator may be able to complete a determination in about 3 hr. Extreme care is necessary in the entire procedure. The method may be applied to other types of cement besides portland cement, although if the cement contains a large amount of acid-insoluble matter, the emulsions may separate slowly, and less vigorous shaking, more chloroform, and more washing may be necessary.

first 250-ml. funnel. When the chloroform separates, draw it into an Erlenmeyer flask (Note 3), taking care not to allow any water to enter the flask.

NOTE 2.—There is usually a dark colored scum at the liquid interface. It may contain chloroform-soluble organic substance after shaking in the funnel, where the proportion of water to chloroform is great. It may be concentrated and confined to a small volume by gently twirling the funnel after the scum has been drawn into the narrower part of the funnel.

NOTE 3.—The liquid is later distilled. No cork or rubber stoppers should be used. A 250- or 300-ml. soil analysis flask, fitted with a condenser tube by means of a ground joint, is satisfactory. The tube may be bent near the neck and the remaining part fitted with a water-cooling jacket. Chloroform thus recovered may be reused as directed in Section 26.

(*c*) Rinse the original large beaker with 25 ml. of chloroform, and add the liquid to the 1-liter separatory funnel. Carry out the operations as described above, retaining the original wash water in the 250-ml. funnels. Repeat, using another 25-ml. portion of chloroform.

(*d*) Distill the combined chloroform extracts in the Erlenmeyer flask until their volume is reduced to 10 to 15 ml. Filter the remaining liquid into a weighed 100-ml. glass beaker or platinum dish (Note 4) through a small filter paper that has been washed with chloroform. Rinse the flask and wash the paper with several small portions of chloroform. Evaporate the extract at a low temperature (not over 63 C.) to dryness (Note 5) and heat it in an oven at 57 to 63 C. for 3 min. Pass dry air into the vessel for 15 sec., cool, and weigh. Repeat the heating and weighing until two successive weighings do not differ by more than 0.0010 g. The higher of the last two weights is taken as the true weight.

NOTE 4.—A platinum dish is preferable, as it quickly attains the temperature of the balance. If a glass beaker is used, it should be allowed to stand in the case of the balance for at least 20 min. before the weighing.

NOTE 5.—Care should be taken in drying the extract, as many of the chloroform-soluble organic substances are somewhat volatile when heated for a long time at even moderate temperatures. With protection from the accumulation of dust, the solution may be evaporated at room temperature overnight.

When a quick evaporation is desired, the solution may be evaporated on a hot plate at a low heat under a stream of dry air through a glass tube (about 1 cm. in inside diameter) until it is about 0.3 cm. in depth. Then remove the vessel from the hot plate and continue a slow stream of dry air until the residue appears dry. Then continue with a more rapid stream of dry air for 5 min. at room temperature before placing the vessel in the oven at 57 to 63 C. After each 3-min. heating period in the oven, pass dry air into the vessel for about 15 sec. before weighing. The air may be dried by passing it through a cheap desiccant, such as calcium chloride or sulfuric acid, followed by a desiccant of high efficiency, such as magnesium perchlorate or anhydrous calcium sulfate, with care taken to avoid the carrying of dust from the desiccant by the air. Instead of using compressed air, which is often contaminated with oil, dirt, and moisture, one can place the chloroform solution under a bell glass and induce a stream of air through the desiccants by means of an aspirator or vacuum pump.

(*e*) *Blank.*—Make a blank determination, using 40 g. of the cement which is ignited at 950 to 1000 C. for 1 hr. (Note 6) and reground, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

NOTE 6.—Care should be taken to completely burn off the organic substance. A 100-ml. flat platinum dish, in which the sample is well spread out, and a muffle furnace are advised for this purpose. If such a furnace is not available, a large high-temperature burner of the Meker type may be used. Thorough stirring of the sample should be done frequently—every 5 min. when a burner is used.

(*f*) *Calculation.*—Calculate the percentage of chloroform-soluble organic substances to the nearest 0.001 by mul-

tiplying the weight in grams of residue (Note 7) by 2.5, (100 divided by the weight of sample used (40 g.).

NOTE 7.—If the organic substance in the cement is tallow, the residue is the fatty acids resulting from the hydrolysis of the tallow in the hot acid solution, and its weight should be multiplied by 1.05 to give the weight of the original glycerides in the tallow. If the original substance is calcium stearate, the residue is stearic acid, and its weight multiplied by 1.07 gives the weight of calcium stearate.

FREE CALCIUM OXIDE IN PORTLAND CEMENT AND CLINKER

Reagents

28. (*a*) *Phenolphthalein Indicator.*—Dissolve 1 g. of phenolphthalein in 100 ml. of absolute ethanol, and neutralize the solution with NaOH dissolved in absolute ethanol.

(*b*) *Glycerol-Ethanol Solvent.*—Prepare a solution consisting of 1 part by volume of glycerol (Note 1) and 5 parts by volume of absolute ethanol (Note 2). To each liter of this solution add 2 ml. of the indicator. The solvent should be slightly alkaline (Note 3) to the indicator. If the solvent is colorless, add a dilute solution of NaOH in absolute ethanol until a slight pink color appears. If the initial color is pink, remove it with the standard ammonium acetate solution (Paragraph (*c*)) and add the NaOH solution until a slight pink color appears. Heat 60 ml. of the solvent to boiling. If the pink color persists, add one small drop of the standard solution of ammonium acetate (0.02 ml., equivalent to 0.0001 g. CaO) to the hot solvent. If the pink color does not disappear, the solvent contains too much alkali, which should be reduced. The solvent, if allowed to stand for a considerable length of time, may become slightly acid and should be checked and, if necessary, readjusted from time to time. (Note 4.)

NOTE 1.—The glycerol should conform to the requirements for glycerol of the Committee on Analytical Reagents of the American Chemical Society.[6] Water is not usually included by the manufacturer in the list of impurities on the label but is usually present. The water content should not exceed about 5 per cent. The test should be made with a pycnometer at 25 C. and the specific gravity at 25/25 C. should be not less than 1.249.

NOTE 2.—Absolute ethanol may be replaced by anhydrous ethanol denatured according to Formula No. 3a or 2b of the U. S. Bureau of Internal Revenue. The alcohol is 95 per cent ethanol and 5 per cent methanol according to Formula No. 3a or 99.5 per cent ethanol and 0.5 per cent benzol according to Formula No. 2b.

NOTE 3.—While a solvent that is exactly neutral at the boiling point is the ideal, it is difficult to prepare due to the end point not being sharp and the danger of adding too much ammonium acetate. The error due to slight alkalinity is not more than 0.01 per cent in a determination of free CaO and may be disregarded. In preparing the solvent, the end point may be better observed if the solvent is put in a tall cylinder placed on white paper. The solvent may be observed from the top and the color matched with that of acidified solvent in a similar cylinder.

NOTE 4.—Glycerol and ethanol are highly hygroscopic. Every effort should be made to avoid exposing them and other materials unnecessarily to water and CO_2 in air. Bottles with an outlet near the bottom or fitted with a siphon are convenient. They can be filled to the top and protected with tubes containing soda lime. Condensers may also be fitted with such tubes at the top.

(*c*) *Standard Ammonium Acetate Solution (1 ml. = 0.005 g. CaO).*—Prepare a standard solution of ammonium acetate in absolute ethanol as follows: Dissolve 16 g. of crystalline ammonium acetate (Note 5) in 1 liter of ethanol. Standardize this solution by titrating against pure CaO that is *freshly* prepared by calcining pure calcium carbonate or calcium oxalate in a platinum crucible at 900 to 1000 C. to constant weight. When the calcined CaO has cooled in a desiccator, perform the following operations in quick succession: grind it in an agate mortar, weigh out 0.05 to 0.06 g. into a dry 200- or 250-ml. Erlenmeyer

flask, and add 60 ml. of the glycerol-ethanol solvent to the flask (Note 6). Disperse the CaO in the solution by shaking the flask and attach a reflux condenser (Note 7). Boil the mixture. The ebullition should be positive but not so violent as to cause bumping or excessive evaporation. Then remove the condenser and immediately titrate the solution, while near boiling, with the standard ammonium acetate solution. Replace the condenser and boil the solution again. Repeat the titrations at intervals (Note 8). Shake the flask frequently between titrations to shorten the time required for the boiling. The titration is complete when no further color appears in the solution during continuous boiling for 1 hr. (Note 9). Calculate the CaO equivalent of the ammonium acetate solution in grams per milliliter by dividing the weight of CaO used by the volume of solution required.

NOTE 5.—Ammonium acetate is generally sold in a damp condition and should be as dry as possible. It may be dried over a drying agent for two weeks or more.

NOTE 6.—Sometimes pure CaO will cake on the bottom of the flask, particularly if the glycerol is anhydrous. This trouble may be avoided by putting a few grams of clean, dry quartz sand in the flask before the introduction of CaO and solvent.

NOTE 7.—If a new stopper is used and has white powder on it, it should be thoroughly washed before using. A glass tube about 6 mm. in diameter and 50 to 100 cm. in length may be used as an air-cooled condenser, but a short condenser is not recommended because a loss of alcohol is liable to occur through evaporation. In such a case it is necessary to add neutralized ethanol from time to time to maintain the same proportion of glycerol to ethanol. If the proportion is greater than one to three, a partial decomposition of cement may take place. Instead of an ordinary flask, plain tubing, and a stopper, a flask with a ground-in glass stopper and condenser tube may be used, preferably one with a standard-taper joint. A water-cooled condenser is the most satisfactory and it may be as short as 1 ft. Some loss of alcohol may also occur through dripping from the condenser during the titrations and should be compensated for by the addition of neutralized ethanol.

NOTE 8.—In general the intervals may be 20 min. but they will chiefly depend on the rapidity of the dissolution of CaO. They may be 5 to 10 min. in the beginning and then be increased to 30 min. or 1 hr. in the end. If the solution contains a large amount of dissolved CaO and its boiling is continued a long time without titration, crystals (probably calcium glyceride) may form which dissolve slowly and increase the time required for the completion of the titration.

NOTE 9.—The end point will not be the same for a hot solution and a cold solution, especially when a large amount of calcium acetate is present. The titration should always be carried out while the solution is boiling hot. If the end point is determined accurately, the solution will turn pink upon cooling, and this can serve as evidence that the end point has not been greatly overstepped.

Procedure

29. (*a*) Weigh 1 g. of finely ground clinker or cement (Note 1) into a flask, add 60 ml. of the solvent to the flask, and proceed as in the standardization of the ammonium acetate solution (Section 28 (*c*)). The end point is considered to be reached when the content of free CaO in the sample does not increase by more than 0.05 per cent during the last 2 hr. of boiling (Note 2).

NOTE 1.—The method is designed especially for fresh clinker. As the method does not differentiate between free CaO and free $Ca(OH)_2$, any free $Ca(OH)_2$ that may be present will be included in the determination and calculated as free CaO. The method may be applied to cement or aged clinker, if desired, but the possibility of the presence of free $Ca(OH)_2$ should be kept in mind.

The sample should be fine enough to pass completely through a standard No. 200 (74-micron) sieve. If it is not, take about 1.2 g. of the sample and sieve it with a small clean No. 200 (74-micron) sieve. Grind the residue in an agate mortar until it is fine enough to pass through the sieve. Mix all the screenings and ground residue thoroughly, grind slightly over 1 g. rapidly in the agate mortar for 2 or 3 min., and take 1 g. for the determination of free CaO. Avoid unnecessary exposure of the sample

to the atmosphere. If the sample is fine enough to pass completely through the sieve, grind slightly over 1 g. as above before weighing 1 g. for the determination.

NOTE 2.—No excess of ammonium acetate should be added at any time because an excess of it may react with calcium aluminate and silicates. To avoid such excess, use a small burette or measuring pipette fitted with a glass stopcock or a rubber pinchcock and small tip which delivers about 50 drops per milliliter. If the titrations are far apart and the reagent evaporates in the tip, a few drops may be discarded before each titration and the drops used in titration may be counted and converted in terms of milliliters. It is a good precaution to allow a slight pink color to remain in the solution after each of the early titrations.

Vigorous boiling is more essential with cement than with pure CaO and, if possible, should be so conducted that it is not necessary to shake the flask vigorously at intervals. The flask should not be shaken vigorously while it is disconnected from the condenser because the solvent, if superheated, may boil, expel alcohol vapor, and then draw in air carrying water and CO_2. A good procedure is to bring the solution and sample to boiling rapidly over a bunsen flame in the beginning before placing the flask on a hot plate and connecting it with the condenser. If there is a tendency to bump, it may be reduced by adding glass beads or pure quartz sand to the flask or putting a thin mat of asbestos between the flask and the hot plate.

If in the final titrations there is doubt as to the exact end point, add a drop of the indicator to the quiescent liquid in the flask and carefully observe the point where the indicator strikes the liquid. If no color appears, the end point has been reached. If the sample settles during boiling and leaves a partially clear layer of solution, another way to overcome difficulty in discerning a change in the color of the solution is to swirl the flask after the addition of the solution of ammonium acetate so as to avoid the dispersion of the sample. A strong daylight lamp with a reflector may be used as an aid in the discernment of the end point. The contents of the flask may be matched with similar contents in another flask which contains an excess of ammonium acetate.

If it is necessary to leave the determination uncompleted, remove the flask, add just enough ammonium acetate to discharge the pink color, and stopper the flask tightly. When renewing the determination, boil the mixture before repeating the titrations.

(*b*) *Calculation.*—Calculate the percentage of free CaO to the nearest 0.1 as follows:

$$\text{Free CaO, per cent} = EV \times 100$$

where:

E = CaO equivalent of the ammonium acetate solution in grams per milliliter, and

V = milliliters of ammonium acetate solution required by the sample.

ALTERNATE METHODS

NOTE.—The alternate methods described in Sections 30 to 43, inclusive, are provided for those who wish to use procedures shorter or more convenient than the preceding ones for the routine determination of certain components. In case of dispute, results obtained according to Sections 8 to 29, inclusive, shall govern.

SILICON DIOXIDE

Alternate Method

Procedure

30. (*a*) Mix thoroughly 0.5 g. of the sample and about 0.5 g. of NH_4Cl in a 50-ml. beaker, cover the beaker with a watch glass, and add cautiously 5 ml. of HCl, allowing the acid to run down the lip of the covered beaker. After the chemical action has subsided, lift the cover, add one or two drops of HNO_3, stir the mixture with a glass rod, replace the cover, and set the beaker on a water bath for 30 min. (Note 1). During this time of digestion, stir the contents occasionally and break up any remaining lumps to facilitate the complete decomposition of the cement. Fit a medium-texture filter paper to a funnel, transfer the precipitate to the filter as completely as possible without dilution, and allow the solution to drain through. Scrub the beaker with a rubber policeman and rinse the beaker and policeman.

Wash the filter two or three times with hot HCl (1:99) and then with ten or twelve small portions of hot water, allowing each portion to drain through completely. Reserve the filtrate and washings for the determination of $Al_2O_3 + Fe_2O_3$ (Note 2).

NOTE 1.—A hot plate may be used instead of a water bath if the heat is so regulated as to approximate that of a water bath.

NOTE 2.—Determine $Al_2O_3 + Fe_2O_3$ by the procedure described in Section 9. Reserve the combined filtrates for the determination of CaO (Section 13 or 32).

(*b*) Transfer the filter paper and residue to a weighed platinum crucible, dry, and ignite, at first slowly until the carbon of the paper is completely consumed without inflaming and finally at 1050 to 1100 C. for 1 hr. Weigh the residue as SiO_2.

(*c*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*d*) *Calculation.*—Calculate the percentage of SiO_2 to the nearest 0.1 by multiplying the weight in grams of SiO_2 by 200, (100 divided by the weight of the sample used (0.5 g.)).

CALCIUM OXIDE

Alternate Method

NOTE.—See Note immediately preceding Section 30.

Reagents

31. *Standard Potassium Permanganate Solution (0.18 N).*—Prepare a solution of $KMnO_4$ on the basis of 5.64 g. per l. The solution should not be filtered through any filter containing organic matter. It is most convenient to siphon off clear solution without disturbing the sediment on the bottom of the bottle. Standardize the solution against 0.7500 g. of sodium oxalate oxidimetric standard furnished by the National Bureau of Standards (standard sample No. 40) according to the directions furnished with the sodium oxalate. If the burette reading is 62.77 ml., the solution contains 0.0056357 g. of $KMnO_4$ per milliliter, which is equivalent to exactly 0.005 g. of CaO. Because of impurities and deterioration, the reading in the standardization is usually not 62.77 ml. Calculate the CaO equivalent of the solution in grams per mill liter as follows:

$$E = \frac{0.31385}{V}$$

where:

E = CaO equivalent of the $KMnO_4$ solution in grams per milliliter,

V = milliliters of $KMnO_4$ solution required by 0.7500 g. $Na_2C_2O_4$, and

0.31385 = 62.77 multiplied by 0.005.

NOTE.—The solution is intended to be equivalent to 0.005 g. of CaO per milliliter, or 1 per cent CaO in a 0.5-g. sample for each milliliter. The numbers 0.0056357 and 62.77 are obtained as follows: 0.005 g. of CaO multiplied by the molecular ratio of 2 $KMnO_4$ to 5 CaO gives 0.0056357 g. of $KMnO_4$. 0.75 g. of $Na_2C_2O_4$ multiplied by the molecular ratio of 2 $KMnO_4$ to 5 $Na_2C_2O_4$ gives 0.35375 g. of $KMnO_4$. 0.35375 g. divided by 0.0056357 g. per ml. gives 62.77 ml.

Procedure

32. (*a*) Add a few drops of NH_4OH to the combined filtrates obtained in the determination of $Al_2O_3 + Fe_2O_3$, (Note 2, Section 30), and bring the solution to boiling. Add to the boiling solution 25 ml. of boiling ammonium oxalate (50 g. per l.) and continue the boiling for 5 to 10 min.; then allow the solution to stand for 15 to 20 min. Filter, and wash the precipitate eight to ten times with hot water, the total amount of water used in rinsing the beaker and washing

not to exceed 75 ml. Reserve the filtrate for the determination of MgO (Section 33). Wash the precipitate back into the original beaker, and add 200 ml. of water and 10 ml. of H_2SO_4 (1:1). Heat the solution just short of boiling, and titrate it with the standard $KMnO_4$ solution (Note 1) to a permanent pink color. Add the filter paper and macerate it. Continue the titration slowly until the pink color is permanent for 10 sec.

NOTE 1.—The temperature of the standard $KMnO_4$ solution should not vary from its standardization temperature so much as to cause a serious error in the determination of CaO. At ordinary room temperatures the volume of pure water changes to the extent of 0.01 to 0.04 per cent for each degree Centigrade, depending on the temperature.

(*b*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents (Note 2), and correct the results obtained in the analysis accordingly.

NOTE 2.—When the amount of calcium oxalate is very small, its oxidation by $KMnO_4$ is slow to start. Before the titration, add a little $MnSO_4$ to the solution to catalyze the reaction.

(*c*) *Calculation.*—Calculate the percentage of CaO to the nearest 0.1 as follows:

$$\text{CaO, per cent} = EV \times 200$$

where:

E = CaO equivalent of the $KMnO_4$ solution in grams per milliliter,
V = milliliters of $KMnO_4$ solution required by the sample, and
200 = 100 divided by the weight of sample used (0.5 g.).

MAGNESIUM OXIDE

NOTE.—Alternate method A may be used when it is desired to determine MgO in the filtrate from the determination of CaO (Section 32). Alternate method B or C may be used when the determinations of SiO_2, Al_2O_3, Fe_2O_3, and CaO are omitted.

Alternate Method A

Rapid Gravimetric Determination

NOTE.—See Note immediately preceding Section 30.

Procedure

33. (*a*) Acidify the filtrate from the determination of CaO (Section 32) with HCl and evaporate by boiling to about 250 ml. Cool the solution to room temperature, and add 10 ml. of $(NH_4)_2HPO_4$ (100 g. per l.) and 30 ml. of NH_4OH. Stir the solution vigorously during the addition of NH_4OH and then for 10 to 15 min. longer. Let the solution stand for at least 8 hr. in a cool atmosphere and filter. Wash the residue five or six times with NH_4OH (1:20) and ignite in a tared crucible, at first slowly until the filter paper is charred and then burned off, and finally at 1050 to 1100 C. for 30 to 45 min. Weigh the residue as $Mg_2P_2O_7$.

(*b*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*c*) *Calculation.*—Calculate the percentage of MgO to the nearest 0.1 as follows:

$$\text{MgO, per cent} = W \times 72.4$$

where:

W = grams of $Mg_2P_2O_7$, and
72.4 = molecular ratio of 2 MgO to $Mg_2P_2O_7$ (0.362) divided by the weight of sample used (0.5 g.) and multiplied by 100.

Alternate Method B

Rapid Determination by Alkalimetry

NOTE.—See Note immediately preceding Section 30.

Reagents

34. (*a*) *Trinitrobenzene Indicator.*—Dissolve 1.0 g. of 1-3-5-trinitrobenzene in 100 ml. of ethanol (95 to 100 per cent).

(*b*) *Phenolphthalein Indicator.*—Dissolve 0.4 g. of phenolphthalein in 100 ml. of ethanol (50 per cent).

(*c*) *Standard Sodium Hydroxide Solution (0.33 N).*—Dissolve 13.0 g. of NaOH in water, add 10 ml. of a freshly filtered, saturated $Ba(OH)_2$ solution, and dilute to 1 liter with water that has been recently boiled and cooled. Shake the solution from time to time for several hours, and filter into a tubulature bottle fitted with an automatic burette. Protect the solution from CO_2 in the air, with soda-lime tubes at the top of the bottle and the burette.

Standardize against acid potassium phthalate or benzoic acid acidimetric standards furnished by the National Bureau of Standards (standard samples Nos. 84 and 39), using the methods in the certificates accompanying the standard samples. Determine the exact normality of the solution, and calculate its MgO equivalent on the basis that 1 ml. of 1 *N* NaOH is equivalent to 0.02016 g. of MgO.

(*d*) *Standard Acid Solution (0.33 N).*—Dilute 32.0 ml. of HCl or 26.0 ml. of HNO_3 to 1 liter with distilled water. Standardize against the standard NaOH solution, using phenolphthalein indicator, and adjust by dilution until the two standard solutions of alkali and acid are of equal strength.

(*e*) *Potassium Iodide-Starch Paper.*—Mix equal volumes of KI (50 g. per l.) and soluble starch solution (10 g. per l.), and dip strips of filter paper into the mixture.

Procedure

35. (*a*) To 5.0 g. of the sample of cement in a 600-ml. beaker, add about 50 ml. of water and 50 ml. of HCl (1:1) and boil until the cement is completely in solution, excepting possibly some SiO_2 which may separate out (Note 1). Add 5 ml. of saturated bromine water and continue the boiling until the excess bromine is completely expelled, as indicated by the absence of a blue coloration on potassium iodide-starch paper when held in the issuing steam. Dilute the solution to about 250 ml. with hot water and add NaOH (200 g. per l.) to the boiling solution from a pipette until the excess acid is neutralized and a permanent precipitate just forms. Continue the boiling and carefully add HCl (1:1) from a pipette until the precipitate dissolves and the solution assumes a yellow $FeCl_3$ color, avoiding much excess of acid. Wash down the sides of the beaker with hot water and continue the boiling for 1 or 2 min., and then remove the beaker from the burner.

NOTE 1.—Some samples of cement, particularly those containing considerable iron or manganese, may require longer boiling or the addition of slightly more HCl to effect complete solution.

(*b*) Cautiously add to the solution 4.0 g. of $CaCO_3$ (weighed to the nearest 0.1 g.). This amount should be sufficient to completely neutralize the acid, with some excess. Dilute the solution to about 400 ml. with hot water and boil vigorously for about 10 min. Remove the beaker from the burner or hot plate, and from a burette carefully add $KMnO_4$ (5 g. per l.) to the hot solution, while stirring vigorously, until the supernatant liquid shows a faint pink color after settling a moment. Avoid the use of more $KMnO_4$ than necessary to produce a faint pink color. Continue the boiling for 2 min., add 2.0 ml. of ethanol, and continue the boiling for a few minutes or until the pink color has disappeared (Note 2).

NOTE 2.—The purpose of the addition of $KMnO_4$ is to remove manganese from the sample,

which otherwise would be precipitated and reported as MgO. The $KMnO_4$ in a hot solution oxidizes the manganese to insoluble MnO_2 and is itself reduced to MnO_2. The ethanol precipitates the excess $KMnO_4$ as MnO_2. In samples containing little or no manganese, this portion of the procedure may be omitted.

(*c*) Transfer the contents of the beaker to a 500-ml. volumetric flask, cool to room temperature, dilute to the mark, and mix by shaking. Filter the solution through dry paper and, after discarding the first 10 or 20 ml. of filtrate, transfer 200 ml. of the filtrate with a pipette to a 500-ml. Erlenmeyer flask. Heat the solution in the flask to boiling and add 3.0 ml. of trinitrobenzene indicator. Add standard NaOH solution, 1.0 ml. at a time, with intermittent boiling for a few seconds, until the magnesium is completely precipitated and a definite pink color persists on boiling. Record the total amount of NaOH used (Note 3).

NOTE 3.—Enough standard NaOH solution should be added to completely precipitate the magnesium without too large an excess which might cause some precipitation of calcium. A guide to proper procedure is the amount of back-titration with acid, which should be held between 1.0 and 2.0 ml. (after being doubled). A little experience with the color change of the trinitrobenzene indicator will enable the operator to hold the back-titration between these limits.

(*d*) Transfer the solution to a 250-ml. volumetric flask, cool to room temperature, dilute to the mark, and mix by shaking. Filter the solution through a dry paper into a graduated cylinder, discarding the first 10 or 20 ml. of filtrate, until 125 ml. of the filtrate are secured. Transfer 125 ml. of the filtrate to a flask, add a few drops of phenolphthalein indicator, and titrate the solution with standard acid solution to the disappearance of the pink color.

(*e*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*f*) *Calculation.*—If the acid and alkali solutions are of equal strength, the quantity of alkali in milliliters minus twice the quantity of acid in milliliters is equivalent to the MgO in a 2-g. sample. Calculate the percentage of MgO to the nearest 0.1 as follows:

$$\text{MgO, per cent} = E\,(V_1 - 2V_2) \times 50$$

where:

E = MgO equivalent of the standard alkali in grams per milliliter,
V_1 = milliliters of standard NaOH solution used,
V_2 = milliliters of standard acid used, and
50 = 100 divided by the weight of sample (2 g.) involved in the titration.

Alternate Method C

Rapid Determination by Titration of Magnesium Oxyquinolate

NOTE.—See Note immediately preceding Section 30.

Reagents

36. (*a*) *8-Hydroxyquinoline Solution.*—Dissolve 25 g. of 8-hydroxyquinoline in 60 ml. of glacial acetic acid. When the solution is complete, dilute to 2 liters with cold water. One milliliter of this solution is equivalent to 0.0016 g. of MgO.

(*b*) *Standard Sodium Thiosulfate Solution (0.1 N).*—Dissolve 25 g. of $Na_2S_2O_3 \cdot 5H_2O$ in 200 ml. of water and dilute to 1 liter. Standardize this solution either on sodium oxalate through a $KMnO_4$ solution, or on As_2O_3 through a solution of resublimed iodine. Standard samples Nos. 40 and 83 of the National Bureau of Standards are convenient for this purpose. One milliliter of exactly 0.1 *N* $Na_2S_2O_3$ is equivalent to 0.000504 g. of MgO.

(*c*) *Standard Potassium Bromate - Potassium Bromide Solution (0.2 N).*—Dissolve 20 g. of KBr and 5.57 g. of $KBrO_3$ in 200 ml. of water and dilute to 1 liter. Obtain the ratio of the strength of this solution to that of the standard $Na_2S_2O_3$ solution as follows: To 200 ml. of water in a 400-ml. beaker add exactly 25 ml. of the standard $KBrO_3$ – KBr solution. Add 20 ml. of HCl, stir, and add immediately 10 ml. of KI (250 g. per l.). Mix well and titrate at once with the $Na_2S_2O_3$ solution until nearly colorless. Add 2 ml. of starch solution, and titrate to the disappearance of the blue color. Calculate the ratio in strength of the standard $KBrO_3$ – KBr solution to the standard $Na_2S_2O_3$ solution by dividing the volume of $Na_2S_2O_3$ solution by the volume of $KBrO_3$ – KBr solution used in the titration.

(*d*) *Starch Solution.*—To 500 ml. of boiling water add a cold suspension of 5 g. of soluble starch in 25 ml. of water, cool, add a cool solution of 5 g. of NaOH in 50 ml. of water, add 15 g. of KI, and mix thoroughly.

Procedure

37. (*a*) To 0.5 g. of the sample of cement in a 400-ml. beaker add 10 ml. of water and 10 ml. of HCl. Heat gently and grind any coarse particles with the flattened end of a glass rod until decomposition is complete. Add hot water to make a total volume of 100 ml.

(*b*) Add 3 drops of methyl red indicator (2 g. per liter of ethanol) to the solution and then add NH_4OH until the solution is distinctly yellow. Heat this solution to boiling and boil for 1 to 2 min. Remove from the burner or hot plate and allow to stand until the precipitate has settled. Filter the solution without delay and wash the precipitate twice with hot NH_4Cl (20 g. per l.). Transfer the precipitate with the filter paper to the beaker and dissolve in 10 ml. of HCl (1:1). Dilute to about 100 ml. and heat to boiling. Reprecipitate, filter, and wash the hydroxides as above. Add 1 ml. of NH_4OH to the filtrate. Heat the filtrate to boiling and, while boiling, add 25 ml. of hot ammonium oxalate (50 g. per l.) and continue the boiling for 2 min. Continue the digestion on the steam bath for 10 to 15 min.

(*c*) Cool the solution to 70 C. and add 10 to 25 ml. of the 8-hydroxyquinoline reagent (Note 1) and then 4 ml. of NH_4OH per 100 ml. of solution. Stir the solution on a mechanical stirring machine for 15 min. and set aside until the precipitate has settled (Note 2). Filter the solution and wash the precipitate with hot NH_4OH (1:40). Dissolve the precipitate in 50 to 75 ml. of hot HCl (1:9), dilute the resulting solution to 200 ml., and add 15 ml. of HCl. Cool the solution to 25 C. and add 10 to 35 ml. of the standard $KBrO_3$ – KBr solution (Note 3) from a pipette. Stir the solution and allow to stand for about 30 sec. to insure complete bromination. Add 10 ml. of KI (250 g. per l.). Stir the resulting solution well and then titrate with the standard $Na_2S_2O_3$ solution until the color of the iodine becomes faintly yellow. At this point add 2 ml. of the starch solution and titrate the solution to the disappearance of the blue color.

NOTE 1.—An excess of the 8-hydroxyquinoline reagent should be used. If it is small the result of the determination of MgO may be low; on the other hand, if it is large the result may be high. The following guide may be used.

Approximate Content of MgO, per cent	Approximate Amount of Reagent Required, ml.
0 to 1.5	10
1.5 to 3.0	15
3.0 to 4.5	20
4.5 to 6.0	25

NOTE 2.—The precipitate should be filtered within an hour. Prolonged standing may cause high result.

NOTE 3.—The amount of the standard $KBrO_3$ – KBr solution used may be as follows:

Approximate Content of MgO, per cent	Amount of Standard $KBrO_3$ – KBr Solution, ml.
0 to 1	10
1 to 2	15
2 to 3	20
3 to 4	25
4 to 5	30
5 to 6	35

(*d*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*e*) *Calculation.*—Calculate the percentage of MgO to the nearest 0.1 as follows (Note 4):

$$\text{MgO, per cent} = E\,(V_1R - V_2) \times 200$$

where:

E = MgO equivalent of the $Na_2S_2O_3$ solution in grams per milliliter,
V_1 = milliliters of $KBrO_3$ – KBr solution used,
R = ratio in strength of the $KBrO_3$ – KBr solution to the $Na_2S_2O_3$ solution,
V_2 = milliliters of $Na_2S_2O_3$ solution used, and
200 = 100 divided by the weight of sample used (0.5 g.).

NOTE 4.—V_1R represents the volume of $Na_2S_2O_3$ solution equivalent to the volume of $KBrO_3$ – KBr solution used. V_2 represents the amount of $Na_2S_2O_3$ required by the excess $KBrO_3$ – KBr which is not reduced by magnesium oxyquinolate.

PHOSPHORUS PENTOXIDE

Alternate Method

NOTE.—See Note immediately preceding Section 30.

Reagents

38. (*a*) *Ammonium Molybdate Solution.*—Prepare the solution in accordance with Section 21 (*a*).

(*b*) *Standard Sodium Hydroxide Solution (0.3 N).*—Dissolve 12 g. of NaOH in 1 liter of water that has been freshly boiled to expel CO_2 and cooled. Add 10 ml. of a freshly filtered, saturated solution of $Ba(OH)_2$. Shake the solution frequently for several hours, and filter it. Protect it from contamination by CO_2 in the air. Standardize the solution against standard acid potassium phthalate (standard sample No. 84) or benzoic acid (standard sample No. 39) furnished by the National Bureau of Standards, according to the directions furnished with the standard. Calculate the P_2O_5 equivalent (Note) of the solution in grams per milliliter as follows:

$$E = N \times 0.003086$$

where:

E = P_2O_5 equivalent of the NaOH solution in grams per milliliter,
N = normality of the NaOH solution, and
0.003086 = P_2O_5 equivalent of 1 N NaOH in grams per milliliter.

NOTE.—The value of the solution is based on the assumption that the phosphorus in cement is precipitated as $2(NH_4)_3PO_4 \cdot 12MoO_3$ and that the precipitate reacts with the NaOH solution thus:

$$2(NH_4)_3PO_4 \cdot 12MoO_3 + 46NaOH = 2(NH_4)_2HPO_4 + (NH_4)_2MoO_4 + 23Na_2MoO_4 + 22H_2O.$$

The number 0.003086 is obtained by dividing the molecular weight of P_2O_5 (141.96) by 46 (for 46 NaOH in the equation) and by 1000 (number of milliliters in 1 liter).

As the actual composition of the precipitate is influenced by the conditions under which the precipitation is made, it is essential that all the details of the procedure are followed closely as prescribed.

(*c*) *Standard Sulfuric Acid Solution (0.15 N).*—Dilute 4.0 ml. of H_2SO_4 to 1 liter with water that has been freshly boiled and cooled. Standardize against the standard NaOH solution. Deter-

mine the ratio in strength of the standard H_2SO_4 solution to the standard NaOH solution by dividing the volume of NaOH solution by the volume of H_2SO_4 solution used in the titration.

Procedure

39. (*a*) Weigh 1 to 3 g. of the sample (Note 1) and 10 g. of NH_4NO_3 into a 150-ml. beaker. Mix the contents, add 10 ml. of HNO_3, and stir quickly, using the flattened end of a glass rod to crush lumps of cement, until the cement is completely decomposed and the thick gel of SiO_2 is broken up. Cover the beaker with a watch glass, place it on a water bath or a hot plate at approximately 100 C. for 15 to 20 min., and stir the contents occasionally during the heating. Add 20 ml. of hot water to the beaker and stir the contents. If the cement contains an appreciable amount of manganese, as shown by the presence of a red or brown residue, add a few milliliters of $NaNO_2$ (50 g. per l.) to dissolve this residue. Boil the contents of the beaker until all nitrous fumes are completely expelled. This should not take more than 5 min., and water should be added to replace any lost by evaporation. Filter into a 400-ml. beaker under suction and with a platinum cone to support the filter paper, and wash the residue of SiO_2 until the volume of filtrate and washings is about 150 ml.

NOTE 1.—The amounts of sample and reagents used depend on the content of phosphorus in the cement. The minimum requirements are sufficient if the cement contains 0.5 per cent P_2O_5 or more. The maximum amounts are required if the content of P_2O_5 is 0.1 per cent or less.

(*b*) Heat the solution to 69 to 71 C., remove it from the heat source, and immediately add 50 to 100 ml. of the ammonium molybdate solution. Stir the solution vigorously for 5 min., wash down the sides of the beaker with cool KNO_3 solution (10 g. per liter of water freshly boiled to expel CO_2 and cooled), cover the beaker with a watch glass, and allow to stand 2 hr. Using suction, filter the precipitate (Note 2), decanting the solution with as little disturbance to the precipitate as possible. Stir the precipitate in the beaker with a stream of the cool KNO_3 solution, decant the liquid, then wash the precipitate onto the filter. Scrub the stirring rod and beaker with a "policeman," and wash the contents onto the filter. Wash the precipitate until it is acid-free (Note 3), allowing each portion of wash solution to be sucked completely through before adding the next.

NOTE 2.—The filter may be a small ordinary filter paper supported by a platinum cone, or a small Hirsch funnel may be used with filter paper cut to fit and a thin mat of paper pulp or acid-washed asbestos pulp. The filtration should be carried out with care to avoid any loss of the precipitate. The filter should fit well, and the suction should be started before the filtration and maintained until the end of the washing.

NOTE 3.—About ten washings are usually required. Test the tenth washing with one drop of neutral phenolphthalein indicator (see Paragraph (*c*)) and half a drop of the standard NaOH solution. If a definite pink color lasts at least 5 min., the precipitate is considered to be acid-free; otherwise, continue the washing.

(*c*) Transfer the filter and precipitate to the beaker in which the precipitation took place, using small damp pieces of paper to wipe out the funnel and to pick up portions of the precipitate that may remain on it. Add 20 ml. of cool CO_2-free water to the beaker, and break up the filter by stirring rapidly with the "policeman" that was used to scrub the beaker. Add an excess of the standard NaOH solution, stir the contents until all trace of yellow has disappeared, wash down the stirring rod and sides of the beaker with 50 ml. of cool, CO_2-free water, and add 2 drops of neutral

phenolphthalein indicator (10 g. per liter of ethanol). Treat the solution with a measured quantity of the standard H_2SO_4 solution, sufficient to destroy completely the pink color. Complete the titration with the NaOH solution until there is a definite faint pink color that lasts at least 5 min.

(*d*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*e*) *Calculation.*—Calculate the percentage of P_2O_5 to the nearest 0.01 as follows:

$$P_2O_5, \text{ per cent} = \frac{E(V_1 - V_2 R)}{S} \times 100$$

where:

E = P_2O_5 equivalent of the NaOH solution in grams per milliliter,
V_1 = milliliters of NaOH solution used,
V_2 = milliliters of H_2SO_4 solution used,
R = ratio in strength of the H_2SO_4 solution to the NaOH solution, and
S = grams of sample used.

MANGANIC OXIDE

Alternate Method

NOTE.—See Note immediately preceding Section 30.

Reagent

40. *Standard Potassium Permanganate Solution (0.18 N).*—Prepare a solution of $KMnO_4$ on the basis of 5.64 g. per l. The solution should not be filtered through any filter containing organic matter. It is most convenient to siphon off clear solution without disturbing the sediment on the bottom of the bottle. Standardize the solution against 0.7500 g. of sodium oxalate oxidimetric standard furnished by the National Bureau of Standards (standard sample No. 40) according to the directions furnished with the sodium oxalate. Calculate the Mn_2O_3 equivalent of the solution in grams per milliliter as follows:

$$E = \frac{0.2650}{A}$$

where:

E = Mn_2O_3 equivalent of the $KMnO_4$ solution in grams per milliliter,
A = milliliters of $KMnO_4$ solution required by 0.7500 g. of $Na_2C_2O_4$, and
0.2650 = 0.7500 multiplied by the molecular ratio of 3 Mn_2O_3 to 10 $Na_2C_2O_4$ (0.3534).

NOTE.—The 0.18 *N* solution of $KMnO_4$ specified in Section 31, which is generally used in the routine volumetric determination of CaO in cement and raw materials, is convenient to use. Exactly 0.005 g. of CaO is equivalent to 0.004224 g. of Mn_2O_3.

Procedure

41. (*a*) Place 2 g. of the sample in a 250-ml. beaker and add about 50 ml. of water to the cement. Stir the mixture until it is in suspension and then add about 15 ml. of HCl. Heat the mixture gently until the solution is as complete as possible. Add 5 ml. of HNO_3 and 50 ml. of water to the solution and boil it until most of the chlorine has been expelled. If necessary, add hot water to maintain the solution at a volume of about 100 ml. Stop the boiling and add ZnO powder to the solution until the acid is neutralized. Add an excess of 3 to 5 g. of ZnO powder to the solution and boil it for a few minutes.

(*b*) Without filtering, and while keeping the solution hot (90 to 100 C.) by intermittent or continuous heating, titrate the solution with the standard $KMnO_4$ solution until a drop of it gives

a permanent pink color (Note). When the end point is approached, add the standard solution drop by drop. After each drop, stir the solution, allow the precipitate to settle a little, and observe the color of the upper stratum of the solution by looking through the side of the beaker.

NOTE.—In the case of a cement in which the approximate content of Mn_2O_3 is unknown, a preliminary determination may be made with rapid titration, 0.5 to 1 ml. of the standard solution being added at a time, and without an attempt to keep the solution close to the boiling point.

(*c*) *Blank.*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

(*d*) *Calculation.*—Calculate the percentage of Mn_2O_3 to the nearest 0.01 as follows:

$$Mn_2O_3, \text{ per cent} = EV \times 50$$

where:

E = Mn_2O_3 equivalent of the $KMnO_4$ solution in grams per milliliter,
V = milliliters of $KMnO_4$ solution used, and
50 = 100 divided by the weight of sample used (2 g.).

FREE CALCIUM OXIDE

Alternate Method

NOTE.—See Note immediately preceding Section 30.

Reagents

42. (*a*) *Phenolphthalein Indicator.*—Prepare the indicator as described in Section 28 (*a*).

(*b*) *Glycerol-Ethanol Solvent.*—Prepare the solvent as described in Section 28 (*b*). Either anhydrous $BaCl_2$ or NaCl is used to accelerate the solution of free CaO. If anhydrous $BaCl_2$ is used, dissolve it in the solvent on the basis of 1 g. per 60 ml. of solvent before the solvent is neutralized (Note). If NaCl is used, add 0.5 g. of it to the flask that contains solvent and freshly prepared CaO or sample at the beginning of the standardization or determination as the case may be.

NOTE.—A convenient way to prepare a large amount of solvent is to heat $BaCl_2 \cdot 2H_2O$ at 120 to 130 C. for several hours, dissolve it in hot glycerol (100 to 125 C.) without grinding, and mix the solution with ethanol. If the salt is dehydrated at a much higher temperature, it may be slow to dissolve in hot glycerol or solvent, even when ground.

(*c*) *Standard Ammonium Acetate Solution (0.2 N).*—Prepare and standardize a solution of ammonium acetate as described in Section 28 (*c*), using an accelerator as specified in Paragraph (*b*) of this section.

Procedure

43. Determine free CaO in clinker or cement as directed in Section 29, with the following exceptions:

(*1*) Use anhydrous $BaCl_2$ or NaCl as directed in Section 42 (*b*).

(*2*) The end point is considered to be reached when the content of free CaO does not increase by more than 0.05 per cent during the last hour of boiling (Note).

NOTE.—If the boiling is prolonged too long, the sample may be partially decomposed and the end point may be obscured by colored decomposition products. This alternate method has a tendency to give higher results than the method described in Section 29. Results by the alternate method should be occasionally checked with the other method.

REPORT

Recommended Order for Reporting Analysis

44. The following order is recom-

mended for reporting the results of chemical analysis of portland cement:

Major Components:

SiO_2.....Silicon dioxide
Al_2O_3.....Aluminum oxide
Fe_2O_3.....Ferric oxide
CaO.....Calcium oxide
MgO.....Magnesium oxide
SO_3.....Sulfur trioxide
Loss on ignition

Minor Components:

Na_2O.....Sodium oxide
K_2O.....Potassium oxide
P_2O_5.....Phosphorus pentoxide
Mn_2O_3.....Manganic oxide

Separate Determinations:

Insoluble residue
Chloroform-soluble organic substances
Free calcium oxide
Water-soluble alkali

Standard Methods of

SAMPLING HYDRAULIC CEMENT[1]

A.S.T.M. Designation: C 183 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 183; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover the procedures for sampling hydraulic cement.

Size and Number of Samples; By Whom Taken

2. (*a*) Samples for purpose of tests shall weigh at least 4 lb. each when they are to be composited. Individual test samples, on which all specified tests are to be made, shall weigh at least 8 lb.

(*b*) Test samples shall be either individual or composite samples, as may be specified, and one test sample shall represent not more than 2000 bags unless otherwise specified by the purchaser.

(*c*) The sampling shall be done by or under the direction of a responsible representative of the purchaser.

Sampling from Cars, Trucks, etc.

3. When sampling cement in cars, trucks, boats, warehouses, etc., one sample shall be taken from each 50 bags or portion thereof in the lot and combined to form one test sample. In the case of samples from trucks where the cement is being trucked from one mill, it is permissible to combine the samples from several trucks to form a test sample representing not more than 2000 bags. When bulk shipments are sampled, representative samples shall be taken from well-distributed points.

Sampling from Bulk Storage

4. The cement may be sampled at bulk storage points by any of the methods described in the following Paragraphs (*a*) to (*c*):

(*a*) *From the Conveyor Delivering to Storage.*—One sample of 4 lb. or more shall be taken from at least each 2000 bags passing over the conveyor, except that the sample shall not represent more than 6 hr. of cement production. This may be secured by taking the entire test sample at a single operation, known as the "grab method," or by combining several portions taken at regular intervals, known as the "composite method." When obtaining a composite sample, it shall be secured by combining approxi-

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] These methods formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 – 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

mately equal weights of the cement taken at regular intervals, each portion representing approximately 40 bags. Automatic samplers may be used in obtaining samples.

(*b*) *From Storage at Points of Discharge.*—Sufficient cement shall be drawn from the discharge openings to obtain samples representative of the cement, as determined by the appearance at the discharge openings of indicators placed on the surface of the cement directly above these openings before the drawing of the cement is started. One 4-lb. sample shall be taken for at least each 2000 bags, by either the "grab" or "composite" method as described in Paragraph (*a*).

(*c*) *From Storage by Means of Proper Sampling Tubes.*—When the methods described in Paragraphs (*a*) and (*b*) cannot be applied and when the depth of the cement to be sampled does not exceed 10 ft., samples may be obtained by proper tubes inserted vertically to the full depth of the cement. Samples so taken shall be obtained from points well distributed over the area of storage.

Preparation of Sample

5. (*a*) Samples shall be packed by the purchaser in moisture-proof, airtight containers, which shall be crated, if necessary, by the manufacturer and shipped at the expense of the purchaser. Before testing, samples shall be thoroughly mixed and then passed through a No. 20 (840-micron) sieve in order to break up lumps and remove foreign materials.

(*b*) Composite samples for the tests as required in Section 6 shall be prepared by arranging all test samples in groups, each group representing the number of bags required by the test or tests for which the composite sample is intended. From each of the test samples in a group, equal portions shall be taken, sufficient in amount to form a composite sample large enough to permit making the required physical or chemical determinations. The composite sample thus prepared shall be thoroughly mixed before using.

Number of Tests

6. (*a*) All physical tests required by the purchase specifications shall be made on each test sample taken from cars and trucks (Section 3), with no test sample representing more than 2000 bags.

(*b*) Physical tests on samples taken from bins, boats, warehouses, etc. (Section 4) shall be required as follows:

(*1*) *Time of Setting*, each test sample representing each 2000 bags.

(*2*) *Air Content* (A.S.T.M. Specifications C 175),[3] composite sample representing each 4000 bags.

(*3*) *Fineness* (surface area or 200-mesh fineness as required by the purchase specifications), composite sample representing each 4000 bags.

(*4*) *Strength*, composite sample representing each 4000 bags.

(*5*) *Soundness* (autoclave expansion or steam pat test as required by the purchase specifications), composite sample representing each 12,000 bags.

(*c*) Chemical determinations shall be required as follows:

(*1*) *Sulfur Trioxide* (SO_3), composite sample representing each 4000 bags.

(*2*) *All Specified Chemical Determinations (Except* SO_3), composite sample representing each 20,000 bags.

(*d*) When the total number of bags sampled is less than that specified for any one of the above test or composite samples, all of the respective physical and chemical tests shall be made on the quantity sampled.

[3] Tentative Specifications for Air-Entraining Portland Cement for Concrete Pavements (A.S.T.M. Designation: C 175), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Method of Test for

AUTOCLAVE EXPANSION OF PORTLAND CEMENT[1]

A.S.T.M. Designation: C 151 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C151; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the soundness of portland cement by means of an autoclave test on a 1 by 1-in. neat cement specimen.

Apparatus

2. (*a*) *Scales.*[2a]—The scales and weights used for weighing materials shall conform to the requirements prescribed in Section 2 (*a*) and (*b*) of the Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187).[3]

(*b*) *Glass Graduates.*—Glass graduates of 150-ml. capacity used for measuring the mixing water shall be made to deliver the indicated volume at 20 C. (68 F.). The permissible variation on these graduates shall be plus or minus 1 ml. The main graduation lines of the cylinders shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around the cylinder.

(*c*) *Molds.*—Molds shall provide for 1 by 1-in. test specimens of 10-in. effective gage length. The effective gage length shall be considered as that length between the innermost points of the metal inserts used as reference points. The parts of the molds shall be tight fitting and firmly held together when assembled. The molds shall be made of steel or hard metal not readily attacked by the cement paste. There shall be sufficient material in the sides of the molds to prevent spreading or warping. Each end plate of the molds shall be equipped to hold properly in place, during the setting period, a stainless steel or noncorroding metal reference point having a diameter of $\frac{1}{4}$ in. The reference points shall be set so that their principal axes coincide with the principal axis of the test specimen, and shall extend into the specimen $\frac{5}{8}$ in. The distance between the inner ends of the reference points shall be 10 ± 0.1 in. The distance between opposite faces of the molds shall be 1 ± 0.03 in. The height of the molds, measured separately for each specimen compartment, shall be 1 ± 0.03

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1943, being revised in 1943.

[2a] This paragraph was editorially revised in 1944.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

in., both for new molds and for molds in use.

(*d*) *Autoclave.*—The autoclave shall consist of a high-pressure steam boiler equipped with an automatic pressure control and a safety valve. The capacity of the heating unit shall be such that with maximum load (water plus specimens) the pressure of the saturated steam in the autoclave may be raised to a gage pressure of 295 psi. (absolute pressure about 310 psi.) in 1 to 1½ hr. from the time the heat is turned on. The automatic pressure control shall be capable of maintaining the pressure at 295 ± 10 psi. for at least 3 hr. A gage pressure of 295 ± 10 psi. corresponds to a temperature of 215.7 ± 1.7 C. (420.3 ± 3 F.). The autoclave shall be designed to permit the pressure to drop from 295 psi. to less than 10 psi. in 1 hr. after the heat supply has been shut off. It shall be equipped with a vent valve for allowing the escape of air during the early part of the heating period and for releasing any steam pressure remaining at the end of the 1-hr. cooling period.

(*e*) *Length Comparator.*—Changes in length of the test specimen shall be measured by a dial gage or micrometer comparator having a range of at least 0.3 in. The instrument shall be graduated to at least 0.001 in., and when tested at any point throughout its range, the error shall not be greater than plus or minus 0.002 in. The difference between repeated measurements shall not be greater than 0.001 in. The comparator shall be equipped with a steel reference bar and shall be frequently checked with this reference bar.

Temperature and Humidity

3. (*a*) The temperature of the molding room and dry materials shall be maintained at not less than 20 C. (68 F.) and not more than 27.5 C. (81.5 F.). The temperature of the mixing water and of the moist closet or moist room shall not vary from 21 C. (70 F.) by more than 1.7 C. (3 F.).

(*b*) The moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 90 per cent.

Preparation of Test Specimens

4. (*a*) *Preparation of Molds.*—Molds shall be thinly covered with mineral oil; after this operation the stainless steel or noncorroding metal reference points shall be set, care being taken to keep them clean and free of oil.

(*b*) *Mixing Cement Paste.*[2a]—The standard batch shall consist of 500 g. of cement with sufficient water to give a paste of normal consistency, and shall be mixed in accordance with the procedure described in Section 4 (*a*) of the Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187).[3]

(*c*) *Molding Specimens.*—Immediately following completion of mixing, the test specimen shall be molded in one or two layers, each layer being compacted with the thumbs or forefingers by pressing the paste into the corners, around the reference inserts, and along the surfaces of the molds until a homogeneous specimen is obtained. After the top layer has been compacted, the paste shall be cut off flush with the top of the mold and the surface smoothed with a few strokes of the trowel. During the operations of mixing and molding, the hands shall be protected by rubber gloves.

(*d*) *Storage of Test Specimens.*—After the mold has been filled, it shall be immediately placed in the moist closet or moist room. Specimens shall remain in the molds in the moist closet or moist room for at least 20 hr.; if removed from

the molds before 24 hr., they shall be kept in the moist closet or moist room until tested.

Procedure

5. (*a*) At 24 hr. ± 30 min. after molding, the specimens shall be removed from the moist atmosphere, measured for length, and placed in the autoclave at room temperature in a rack so that the four sides of each specimen will be exposed to saturated steam. The autoclave shall contain enough water to maintain an atmosphere of saturated steam vapor during the entire period of test. Ordinarily, 7 to 10 per cent of the volume of the autoclave should be occupied by the water.

(*b*) To permit air to escape from the autoclave during the early portion of the heating period, the vent valve shall be left open until steam begins to escape. The valve shall then be closed and the temperature of the autoclave shall be raised at such a rate as will bring the gage pressure of the steam to 295 psi. in 1 to 1½ hr. from the time the heat is turned on. The 295 ± 10 psi. pressure shall be maintained for 3 hr. At the end of the 3-hr. period the heat supply shall be shut off and the autoclave cooled at a rate such that the pressure will be less than 10 psi. at the end of 1 hr., and any pressure remaining shall be slowly released by partially opening the vent valve until atmospheric pressure is attained. The autoclave shall then be opened and the test specimens immediately placed in water the temperature of which is above 90 C. (194 F.). The water surrounding the bars shall then be cooled at a uniform rate by adding cold water so that the temperature of the water will be lowered to 21 C. (70 F.) in 15 min. The water surrounding the specimens shall then be maintained at 21 C. (70 F.) for an additional 15 min., when the specimens shall be surface dried and their lengths again measured.[4]

Calculation

6. The difference in length of the test specimen before and after autoclaving shall be calculated to the nearest 0.01 per cent of the effective gage length and shall be reported as the autoclave expansion of the cement. A contraction (negative expansion) shall be indicated by prefixing a minus sign to the percentage expansion reported.

Retests

7. Cement failing to meet the test for soundness in the autoclave may be accepted if it passes a retest, using a new sample, at any time within 28 days thereafter. The provisional acceptance of the cement at the mill shall not deprive the purchaser of the right of rejection on a retest of soundness and time of setting at the time of delivery of the cement to the purchaser.

[4] If it is preferred to make all measurements at 26.5 C. (80 F.), it is recommended that upon removal of the specimens from the moist closet or moist room, they be placed in water maintained at 26.5 C. (80 F.) for at least 15 min., removed and measured for length, and then placed in the autoclave. Upon removal from the autoclave, the specimens and water shall be cooled to 26.5 C. (80 F.) in 15 min. and the specimens kept in water at this temperature for an additional 15 min., and then measured for length.

Standard Method of Test for

FINENESS OF PORTLAND CEMENT BY THE TURBIDIMETER[1]

A.S.T.M. Designation: C 115 - 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 115; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the Wagner turbidimeter[3] apparatus and procedure for determining the fineness of portland cement as represented by specific surface expressed as total surface area in square centimeters per gram of cement.

APPARATUS

Nature of Apparatus

2. The Wagner turbidimeter consists essentially of a source of light of constant intensity adjusted so that approximately parallel rays of light pass through a suspension of the cement to be tested and impinge upon the sensitive plate of a photoelectric cell. The current generated by the cell is measured with a microammeter and the indicated reading is a measure of the turbidity of the suspension. General considerations indicate that turbidity is in turn a measure of the surface area of the suspended sample of cement. The apparatus, illustrated in Fig. 1, shall consist specifically of the parts described in Sections 3 to 9.

Turbidimeter

3. The turbidimeter shall be mounted in a suitable case and shall include the following features:

(*a*) *Source of Light.*—The source of light (Fig. 1) shall consist of a 3 to 6 candlepower, concentrated-filament electric lamp operated by a 6-v. storage battery, or a source of constant emf. A parabolic reflector shall be mounted behind the lamp and the lamp focused in such manner that approximately parallel rays of light will pass through the sedimentation tank and will impinge upon the photoelectric cell. The light intensity shall be regulated by means of two rheostats having resistances of approximately 6 and 30 ohms, respectively, and mounted in series with the lamp but in parallel with each other.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1942, being revised in 1938 and 1941.

[3] This turbidimeter was developed by L. A. Wagner, Research Associate of the Cement Reference Laboratory, National Bureau of Standards, Washington, D. C. A description of the apparatus and mathematical derivations of formulas used are given in the paper, "A Rapid Method for the Determination of the Specific Surface of Portland Cement," by L. A. Wagner, *Proceedings*, Am. Soc. Testing Mats., Vol. 33, Part II, p. 553 (1933).

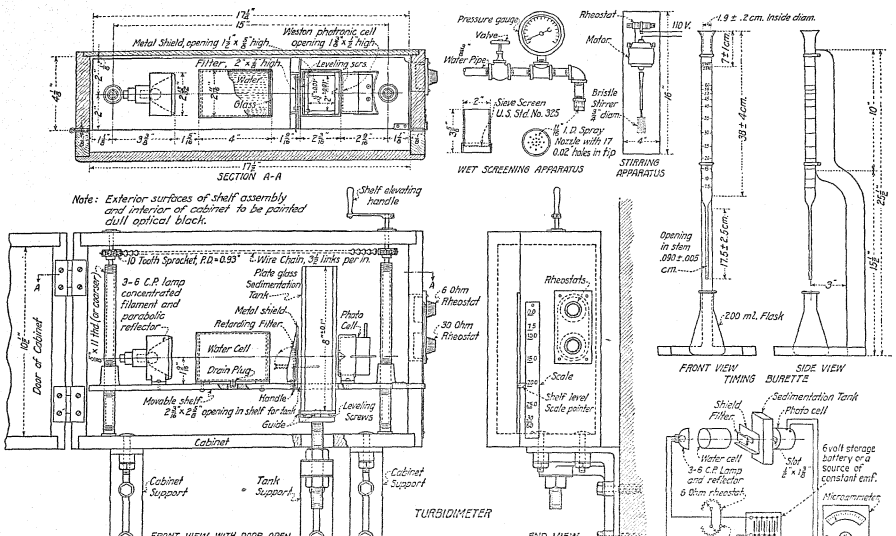

FIG. 1.—Dimensional Details of Turbidimeter Fineness Test Apparatus.

(*b*) *Water Cell.*—The light shall pass through a water cell before entering the sedimentation tank in order that radiant heat from the beam shall be absorbed. The cell shall consist of 3-in. diameter brass tubing, 4 in. in length, with glass windows cemented in the ends with a suitable sealing material. A stoppered hole shall provide for filling with distilled water. The cell shall be so arranged that all rays of light entering the sedimentation tank shall first pass through the water.

(*c*) *Retarding Filter.*—A light-retarding glass or other device shall be provided that will reduce the intensity of light from that corresponding to 100 microamperes to a reading of 20 to 30 microamperes. The light intensity shall be uniformly retarded over the entire area of that portion of the cell which is exposed to light during a test.

(*d*) *Sedimentation Tank.*—The sedimentation tank shall be constructed of $\frac{3}{16}$-in. plate glass cemented together to form a rectangular tank having inside dimensions 2 by $1\frac{1}{2}$ in. by 8 in. in height. The permissible variations on the inside dimensions of the tank shall be plus or minus 0.03 in. in length and width and plus or minus 0.1 in. in height. The 2-in. faces of the tank shall be placed normal to the beam of light, and shall be equidistant within 0.01 in. at all points. A mark shall be placed on the side of the tank to indicate a volumetric content of 335 ml., which is the level to which the tank will be filled in a test.

(*e*) *Photoelectric Cell.*—The means of measuring the light intensity shall be a sensitive photoelectric cell (Weston Photronic type) connected directly to a microammeter. A hood with a horizontal slot $\frac{1}{2}$ in. in height by $1\frac{3}{8}$ in. in width shall be mounted over the face of the photoelectric cell.

(*f*) *Shield.*—A metallic shield having a slot $\frac{5}{8}$-in. in height by $1\frac{1}{2}$ in. in width, as indicated in Fig. 1, shall be placed between the water cell and the sedimentation tank.

(*g*) *Elevating Device.*—The source of light, water cell, photoelectric cell, retarding filter, and shield shall be mounted on a movable shelf which may be raised or lowered, and which may be readily and accurately adjusted so that the turbidity of the suspension may be determined at any desired depth. The sedimentation tank shall be mounted on a base which is independent of the rest of the apparatus so that the tank shall be free from vibration caused by moving the shelf. The level of the light beam with reference to the surface of the suspension shall be indicated by a pointer which will travel along a scale mounted on the cabinet. The zero of the scale shall indicate that position at which the center lines of the slots for the light beam are at the same elevation as the surface of the liquid in the tank when filled to the 335-ml. level. The lines on the scale to be marked 7.5, 10, 15, 20, 25, and 30–60, shall be located at distances from the zero mark equal to values "h" in Table I, and shall indicate the positions at which the pointer should be located when turbidity readings for these particle sizes are taken. The interior of the turbidimeter cabinet and the exterior surfaces of the shelf, parabolic reflector,

TABLE I.—VALUES OF h, d, AND $\frac{h}{d^2}$ TO BE USED IN CALIBRATION OF THE TURBIDIMETER APPARATUS.

Particle Diameter, d, microns	Depth of Suspension, h, cm.	$\frac{h}{d^2}$
60	15	0.00417
55	15	0.00496
50	15	0.00600
45	15	0.00741
40	15	0.00938
35	15	0.01225
30	15	0.01667
25	13.1	0.0210
20	10.0	0.0250
15	6.6	0.0293
10	3.3	0.0333
7.5	2.1	0.0375

water cell, shield, and photoelectric cell hood shall be painted with a dull optical black paint.

Microammeter

4. The microammeter shall have a range of 0 to 50 microamperes, shall be readable to 0.1 microampere, and accurate to 0.25 microampere. The internal resistance of the microammeter shall be between 50 and 150 ohms.

Source of Current

5. A 6-v. automobile starting and lighting storage battery or a source of constant emf. shall be used for supplying current to the lamp.

Sieve

6. The sieve shall be 2 in. in diameter and have side walls 3 in. in height, and shall be fitted with a No. 325 (44-micron) woven wire screen cloth, which cloth shall conform to the requirements of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[4] and be such that the sieve correction factor obtained shall not be greater than 15 per cent (see Section 10 (*b*)).

Stirring Apparatus

7. The stirring apparatus shall consist of either (*a*) a cylindrical brush, $\frac{3}{4}$ in. in diameter and about $1\frac{3}{4}$ in. in length, with an end approximately fitting the contour of the bottom of a $\frac{7}{8}$-in. diameter test tube, or (*b*) any other stirring device that will be equally efficient in dispersion as measured by specific surface determinations on a standard sample. The stirring apparatus shall rotate at a speed of approximately 3500 rpm.

Timing Burette

8. The time of settling for the different sized particles shall be obtained from a burette from which kerosine is allowed to flow. The burette shall consist of a glass tube having a capillary tube fused into the lower end. The upper end of the large tube shall be flared to serve as a funnel for introducing kerosine into the tube. The burette shall conform to the following limiting dimensions:[a]

	Dimension, cm.	Permissible Variation, cm.
Length of large tube	38	± 4
Inside diameter of large tube	1.9	± 0.2
Length of capillary	17.5	± 2.5
Diameter of capillary	0.09	± 0.005
Top of burette to zero line	7	± 1

[a] Since glass tubing of desired dimensions is not always obtainable, the above wide permissible variations allow selection of dimensions to produce a burette having a duration of flow which will permit of calibration as described in Section 10 (*a*).

Suspending Liquid

9. Clear white kerosine shall be used with the turbidimeter apparatus.

CALIBRATION OF APPARATUS

Calibration of Turbidimeter

10. The turbidimeter apparatus shall be calibrated in accordance with the following procedure:

(*a*) *Calibration of Burette Scale.*—For calibration of the burette scale a kerosine having a known viscosity and density for the temperature at which the calibration is to be made shall be used. The times of flow from the burette which correspond to the times of settling for the different sized particles shall be calculated from the following equation:

$$t = \frac{1{,}837{,}000\,u}{(P_1 - P_2)} \times \frac{h}{d^2}$$

where:

t = time of settling, or time of flow in seconds,
u = viscosity of kerosine in poises,
P_1 = density of cement particles in grams per cubic centimeter = 3.15 for portland cement,[a]

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[a] The specific gravity of portland cement does not vary greatly, and in this work it is considered constant at 3.15. A variation of 0.15 from this value when substituted in Stokes' law gives a variation of 2.5 per cent in the diameter of the particle measured.

P_2 = density of kerosine in grams per cubic centimeter,
h = depth of suspension to level of light in centimeters, and
d = diameter of particle in microns.

Values of $\frac{h}{d^2}$ are given in Table I.

The burette shall next be filled with kerosine at the calibrating temperature, a timing clock shall be started at the instant the kerosine in the burette drains past the zero line, and levels reached by the draining kerosine shall be marked on the burette for each of the time intervals, t, calculated as described above. At these marks, permanent lines and numbers indicating the corresponding diameters shall be etched on the burette (Note 1).

The construction and graduation of the burette shall be such that the time required for the kerosine to pass the permanent lines of the burette shall agree with the calculated time of settling within 1 per cent, except that the permissible variation shall be not less than 1 sec.

NOTE 1.—By using the calibrated burette the apparatus may be used within the normal range of room temperatures without further correction, the change in rate of flow of the kerosine from the burette automatically compensating for change in viscosity of the suspension due to temperature. The kerosine in the burette and that of the suspension should be kept the same within 1 F. (0.5 C.). This condition will ordinarily exist if the supply of kerosine is kept in the same room as the apparatus.

Extreme care must be taken to ascertain that only clean kerosine is used in the burette, and in addition the capillary should be examined frequently to make sure that no small pieces of lint or other foreign material have become lodged in it.

(*b*) *Calibration of No. 325 Sieve.*—The spray nozzle and pressure gage shall be connected to a water supply line and the pressure on the spray nozzle adjusted to 10 psi. One gram of the current lot of National Bureau of Standards' Standard Sample No. 114[a] shall be placed on the No. 325 (44-micron) sieve and washed for 1 min. The sieve and residue shall be dried in an oven or over a hot plate (Note 2) and the residue brushed from the sieve and weighed on an analytical balance. The difference between the amount of residue obtained in this manner and the amount of residue indicated by the fineness specified for the standard sample, expressed as a percentage of the former residue, shall be the sieve correction factor (see Note 3; also Table II, footnote *a*).

NOTE 2.—Care should be taken not to heat the sieve hot enough to soften the solder.

NOTE 3.—It should be observed that the sieve correction as specified is a *factor* to be *multiplied* by the residue obtained and that the amount to be added to or subtracted from the residue in any given test is therefore proportional to the amount of residue.

(*c*) *Determination of the Proper Light Intensity, I_0.*—The calibration of the turbidimeter proper shall be made by adjustment of the light intensity, I_0. Increasing the light intensity reduces the calculated surface area of any sample and *vice versa*. Using the regular test procedure described in Sections 12 to 14, and with the light adjusted to a trial value of 25 microamperes through the filter, a determination of the specific surface shall be made using the current lot of National Bureau of Standards' Standard Sample No. 114.[a] If a specific surface greater than that assigned for the standard sample is obtained, the light intensity through the filter shall be increased, the suspension shall be reagitated, and the analysis repeated. If a specific surface less than the assigned value is obtained, the light intensity shall be decreased, the suspension reagitated, and the analysis repeated. Using

[a] Obtainable at the National Bureau of Standards Washington, D. C.

new suspensions, the above procedure shall be repeated twice and the average of the three intensities noted. When the intensity is found which results in a specific surface within plus or minus 15 sq. cm. of the values assigned to the standard sample, the tank shall be removed and the intensity through the filter recorded. The light shall next be adjusted to this average value and a tank of clear kerosine placed in its path. The intensity through the filter plus tank of clear kerosine shall be recorded. This becomes the permanent reference value for the intensity of the light, and the rheostats shall be adjusted at the beginning of each test to give this value through the filter plus tank of clear kerosine from the regular supply.

TEST SAMPLE

Size of Test Sample

11. The size of the sample of cement for test shall be so selected that the microammeter readings will occur in the middle portion of the microammeter scale (Note).

NOTE.—The following approximations will be helpful in many instances in selecting the size of sample: 0.3-g. sample for a cement of which more than 85 per cent passes a No. 325 (44-micron) sieve, 0.4-g. sample for a cement of which 70 to 85 per cent passes a No. 325 sieve, and 0.5-g. sample for a cement of which less than 70 per cent passes a No. 325 sieve.

PROCEDURE

Sieve Determination

12. A No. 325 (44-micron) sieve determination shall be made on a 1-g. sample of the cement in accordance with the procedure specified for calibration in Section 10 (*b*). The percentage (corrected) of cement passing the sieve shall be recorded as *r*. (See Note; also Table II, footnote *a*.)

NOTE.—After three determinations the sieve should be dipped in diluted HCl (1:10) and immediately rinsed with water to remove particles lodged in the meshes. After 25 determinations the sieve should be recalibrated.

Preparation of the Suspension

13. (*a*) The cement sample shall be placed in a test tube with 10 to 15 ml. of kerosine and 5 drops of oleic acid (U.S.P.). (Oleic acid is added as a dispersing agent and has slight or no effect on the viscosity of the kerosine. The oleic acid, which changes with age and exposure to heat and light, should be kept in a well-stoppered dark-glass bottle.) The mixture shall then be stirred for 1 min. with the apparatus described in Section 7 and shall then be transferred to the settling tank, the brush and tube washed with clear kerosine which shall also be added to the suspension, and clear kerosine added until the total volume of the suspension in the tank is 335 ml. (Note 1).

NOTE 1.—Since it is important that the level of the liquid in the tank coincide with the zero mark on the scale of the instrument (see Section 3 (*g*)), it is correspondingly important that the volume of the suspension be close to 335 ml., as specified. This may be accomplished by the use of a flask, calibrated to deliver 335 ml., from which all the kerosine used in making up a suspension is taken; or a point gage may be used, consisting essentially of a flat plate approximately 2 by 2½ in. to the center of which is attached vertically a metal pin of such length that, when the plate is placed in position on top of the tank, the point of the pin is at the 335-ml. level. Either of these methods should insure the position of the liquid level within a few tenths of a millimeter.

(*b*) *Agitation of the Suspension.*—Just before being placed in the path of the light beam, the tank shall be agitated to effect a uniformity of the suspension. The tank shall be covered with a ground-glass cover and oscillated 180 deg. about a horizontal axis, turning the tank upside down and back again to its original upright position approximately once each

second for about 1 min. (Note 2). Care should be taken to prevent loss of kerosine (Note 3). The suspension will then be ready to place in its proper position in the path of the light beam.

NOTE 2.—The procedure described for oscillating the suspension must be carefully followed. The procedure used in shaking a cocktail must not be used.

NOTE 3.—The faces of the glass tank shall be clean when the suspension is added, and care must be taken to avoid as much as possible the necessity of cleaning the faces thereafter.

Procedure

14. The turbidimeter apparatus shall be operated in accordance with the procedure described in the following Paragraphs (*a*) to (*h*):

(*a*) With retarding filter and sedimentation tank containing approximately 100 ml. of clear kerosine in the light path, the light shall be adjusted to the proper intensity, I_0, by taking repeated readings at 1-min. intervals until an unchanging value shall indicate that the lamp and photoelectric cell are in equilibrium (Note 1).

NOTE 1.—To protect the microammeter, the lamp must never be turned on without a suspension or the retarding filter in position to reduce the light intensity to a value within the range of the microammeter.

(*b*) The proper size of sample of cement (Section 11) shall be weighed and a suspension prepared in accordance with Section 13 (*a*).

(*c*) The shelf level pointer shall be placed at the 30-60-micron position.

(*d*) The burette shall be filled to a suitable height with kerosine from the same lot and at the same temperature as the kerosine used in the suspension, and oscillation of the tank containing the suspension shall be started in accordance with Section 13 (*b*). The oscillation shall be continued until the kerosine drains to the zero line on the burette, when the agitation shall be stopped (Note 2). The tank shall be immediately placed in position in the path of the light beam.

NOTE 2.—The lid to the tank must fit so that no kerosine drains down the outside faces of the tank.

(*e*) The retarding filter shall be immediately removed from the light path and the cabinet door closed.

(*f*) The microammeter shall be read at the instants the kerosine in the burette drains past marks 60, 55, 50, 45, 40, 35, and 30.

(*g*) The shelf shall then be raised successively to the marks 25, 20, 15, 10, and 7.5 on the pointer scale, the microammeter being read at each position as the kerosine drains past the corresponding mark on the burette.

(*h*) The filter shall be replaced in the path of the light beam, the tank removed, and the intensity of the lamp checked (Note 3).

NOTE 3.—If the microammeter indication has shifted more than 0.3 microampere from the initial setting through the filter alone, the test must be repeated. A freshly charged storage battery should be momentarily short-circuited to reduce the voltage to constant value. If the microammeter indication continues to fluctuate, look for loose connections in the lamp and photoelectric-cell circuits, see that the rheostat contacts are clean, and make certain that the lamp, socket, and reflector are rigidly fixed in their mounting.

CALCULATION

Calculation and Record

15. (*a*) *Specific Surface.*—Specific surface shall be calculated from the following equation:

$$S = \frac{38r(2 - \log I_{60})}{1.5 + 0.75 \log I_{7.5} + \log I_{10} + \log I_{15} + \log I_{20} \ldots + \log I_{55} - 11.5 \log I_{60}}$$

where:

S = specific surface of the sample in square centimeters per gram,

r = corrected percentage by weight passing the No. 325 (44-micron) sieve, and

$I_{7.5}$, I_{10}, I_{15} ... I_{60} = microammeter readings, in microamperes, which correspond to the particle diameters 7.5, 10, 15 ... 60 microns.

NOTE.—The constant factor 38 applies only to a material having the specific gravity of portland cement (approximately 3.15). For any other material there must be calculated the corresponding proper value for this factor which, in the derivation of the formula, varies inversely as the density of the particles (in grams per cubic centimeter).

(*b*) *Recording of Data.*—The form shown in Table II is suggested for the recording of turbidimeter data and calculation of specific surface.

Calculation of Specific Surface from First Turbidity Reading I_{60}

16. (*a*) This method may be used for successive determinations from the same plant, provided, that the same size test samples are used, and that there is no great change in fineness, color, or other properties of the cement. Under these conditions the specific surface of a sample may be calculated from the first turbidity reading, I_{60}, by using the following equation:

$$S = c(2 - \log I_{60})$$

where:

S = specific surface of the sample in square centimeters per gram,

I_{60} = microammeter reading corresponding to particle diameter of 60 microns, and

c = transmittancy constant for the particular plant.

NOTE.—The transmittancy constant "c" may be evaluated by substituting in the above equation known values of S and $2 - \log I_{60}$ as determined from a complete turbidimeter test. The average of not less than five values of "c," as determined from complete tests, should be used in the above equation.

(*b*) If the fineness of a sample as determined in accordance with Paragraph (*a*) fails to conform to the specification requirements for fineness, a retest shall be made by the complete procedure described in Sections 14 and 15.

TABLE II.—ILLUSTRATIVE FORM FOR RECORDING TURBIDIMETER TEST DATA AND CALCULATION OF SPECIFIC SURFACE.

(Values shown are for purpose of illustration only.)

Sample Identification	Sample X
Passing No. 325 (44-micron) Sieve (wet method), r, corrected	89.7 per cent[a]

	Difference =	1.722	

$$S = \frac{38 \times 89.7 \times 0.959}{1.722} = 1900 \text{ sq. cm. per g.}$$

[a] The following example presents an illustration of the determination and application of the sieve correction factor for a No. 325 sieve (wet method):

Determination:

Residue specified for standard sample No. 114c = 10.8 per cent, or a residue for 1-g. test sample	= 0.108 g.
Residue obtained on the sieve, which is being calibrated with standard sample	= 0.100 g.
Difference between specified and test residues	= 0.008 g.
Correction factor for sieve (plus in this example)	$= +\frac{0.008}{0.100} \times 100 = +8.0$ per cent

Application:

Sieve correction factor	= + 8.0 per cent
Residue from the sample under test	= 0.095 g.
Correction = + 0.08 × 0.095 g.	= +0.008 g.
Corrected residue (algebraic sum)	= 0.103 g. = 10.3 per cent
Corrected amount passing sieve (r)	= 89.7 per cent

[b] For convenience in calculation, log I_{60} and log $I_{7.5}$ are recorded in a separate column.

Standard Method of Test for

FINENESS OF HYDRAULIC CEMENT BY THE NO. 200 SIEVE[1]

A.S.T.M. Designation: C 184 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 184; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the fineness of hydraulic cement by means of the No. 200 (74-micron) sieve.

Apparatus

2. (*a*) *Sieve.*—A standard No. 200 (74-micron) sieve shall be used, conforming to the requirements of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11)[3] and certified by the National Bureau of Standards. Wire cloth for standard sieves for cement shall be woven (not twilled) from brass, bronze, or other suitable wire, and mounted without distortion on a frame, about 2 in. (5 cm.) below the top of the frame. The joint between the cloth and frame shall be smoothly filled with solder to prevent lodging of the cement. The sieve frame shall be circular, 8 in. (20.32 cm.) in diameter, and shall be provided with a pan and cover. The correction for the sieve used in this test shall be determined by sieving tests, made in conformity with the procedure of this test method, using a cement standardized for this purpose by the National Bureau of Standards (standard sample No. 46 or No. 47). The difference between the percentage residue on the sieve and that assigned to the standard sample is the amount of the correction, which shall be added or subtracted as necessary.

(*b*) *Balance.*—On balances in use, the permissible variation at a load of 50 g. shall be plus or minus 0.05 g., and at loads less than 0.1 g. the permissible variation shall be plus or minus 0.01 g. The permissible variations on new balances shall be one half of these values. The sensibility reciprocal[4] at each of the

[1] Under the standardization procedure of the Society this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] This method formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 – 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

specified loads shall be not greater than twice the permissible variation specified for the load in question. The balance shall be enclosed in a glass case.

(*c*) *Weights.*—The permissible variations on weights in use in the fineness test shall be as shown in Table I, and the permissible variations on new weights shall be one half of these values.

TABLE I.—PERMISSIBLE VARIATIONS ON WEIGHTS.

Weight, g.	Permissible Variations on Weights in Use, plus or minus, g.
50	0.04
20	0.02
10	0.014
5	0.010
2	0.006
1	0.004
0.500	0.003
0.200	0.002
0.100	0.001
0.050	0.001
0.020	0.001
0.010	0.001

(*d*) *Brush.*—A bristle brush will be required for use in cleaning the No. 200 sieve. A 1- or 1½-in. brush with a 10-in. handle is a convenient size.

Procedure

3. (*a*) A 50-g. sample of the cement shall be placed on the clean, dry No. 200 (74-micron) sieve with the pan attached. Washers, shot, and slugs shall not be used on the sieve. While holding the sieve and pan (without cover) in both hands, the sieving shall be done with a gentle wrist motion until most of the fine material has passed through and the residue looks fairly clean. This operation usually requires only 3 or 4 min. When the residue appears clean the cover shall be placed on the sieve and the pan removed. Then, with the sieve and cover held firmly in one hand, the side of the sieve shall be tapped gently with the handle of the brush used for cleaning the sieve. Dust adhering to the sieve will thus be dislodged and the underside of the sieve may then be swept clean. The pan shall be emptied and wiped out thoroughly with a cloth or waste, the sieve replaced in the pan, and the cover carefully removed. Any coarser material that has been caught in the cover during the tapping shall then be returned to the sieve.

(*b*) The sieving shall be continued (with the cover removed) as described in Paragraph (*a*) for 5 or 10 min., depending on the condition of the cement. The gentle wrist motion involves no danger of spilling the residue, which shall be kept well spread out on the screen. More or less continuous rotation of the sieve shall be carried on throughout the sieving. This open sieving may usually be continued safely for 8 min. or more, but care should be taken that it is not continued too long. The cover shall then be replaced and the same process of cleaning followed as described in Paragraph (*a*). If the cement is in proper condition, there should now be no appreciable dust remaining in the residue nor adhering to sieve or pan.

(*c*) One-minute tests shall be made as follows: The sieve, with pan and cover attached, shall be held in one hand in a slightly inclined position and moved forward and backward in the plane of inclination, at the same time striking the side gently about 150 times per minute against the palm of the other hand on the upstroke. The sieving shall be performed over a white paper, and any material escaping from the sieve or pan and collected on the paper shall be returned to the sieve. After every 25 strokes, the sieve shall be turned about one sixth of a revolution, in the same direction (Note). The sieving operation shall be continued until not more than 0.05 g. passes through in 1 min. of continuous sieving. Then the residue on the sieve shall be transferred to the

balance pan, taking care to brush the sieve cloth thoroughly from both sides to insure the removal of all the residue from the sieve.

NOTE.—Sieve covers may be marked with three straight lines through the center and intersecting at 60 deg. If one of the lines is marked with an arrowhead and the habit is formed of starting with this point under the right hand, one can easily follow the progress of the 1-min. tests.

Calculation

4. The fineness shall be calculated as follows:

$$F = \frac{R}{50} \times 100 + C$$

where:

F = fineness of the cement expressed as percentage residue on the No. 200 (74-micron) sieve,

R = weight of residue on the No. 200 (74-micron) sieve, in grams, and

C = sieve correction, determined as prescribed in Section 2 (*a*) and added as an algebraic sum.

Mechanical Sieving

5. Mechanical sieving devices may be used, but the cement shall not be rejected if it meets the fineness requirement when tested by the hand method described in Section 3.

Standard Method of Test for

NORMAL CONSISTENCY OF HYDRAULIC CEMENT[1]

A.S.T.M. Designation: C 187 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 187; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the normal consistency of hydraulic cement.

Apparatus

2. (*a*) *Scales.*—The scales shall conform to the following requirements: On scales in use the permissible variation at a load of 1000 g. shall be plus or minus 1.0 g. The permissible variation on new scales shall be one half of this value. The sensibility reciprocal[3] shall be not greater than twice the permissible variation.

(*b*) *Weights.*—The permissible variations on weights in use in weighing the cement shall be as prescribed in Table I. The permissible variations on new weights shall be one half of the values in Table I.

(*c*) *Glass Graduates.*—Glass graduates of 100-ml. to 200-ml. capacities used for measuring the mixing water shall be made to deliver the indicated volume at 20 C. (68 F.). The permissible variation shall be plus or minus 1.0 ml. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] This method formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 - 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

[3] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

(*d*) *Vicat Apparatus.*—The Vicat apparatus shall consist of a frame *A* (Fig. 1) bearing a movable rod *B*, weighing 300 g., one end *C*, the plunger end, being 1 cm. in diameter for a distance of at least 5 cm., and the other end having a removable needle *D*, 1 mm. in diameter and 5 cm. in length. The rod *B* is re-

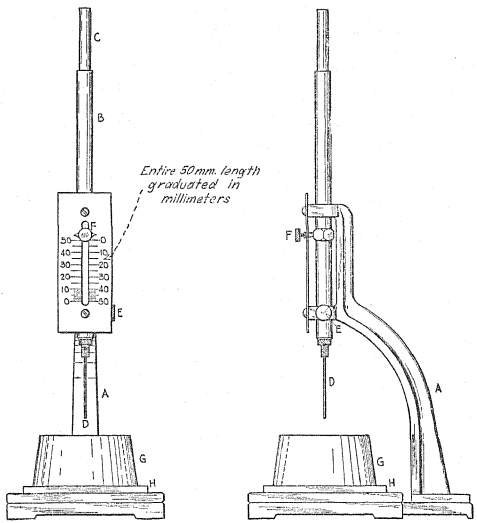

FIG. 1.—Vicat Apparatus.

versible, and can be held in any desired position by a set screw *E*, and has an adjustable indicator *F* which moves over a scale (graduated in millimeters) attached to the frame *A*. The paste is held in a rigid conical ring *G*, resting on a glass plate *H* about 10 cm. square. The ring shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 7 cm. at the base and 6 cm. at the top, and a height of 4 cm. In addition to the above, the Vicat apparatus shall conform to the following requirements:

Weight of plunger	300 ± 0.5 g. (0.661 lb. ± 8 grains)
Diameter of larger end of plunger	1 ± 0.005 cm. (0.394 ± 0.002 in.)
Diameter of needle	1 ± 0.05 mm. (0.039 ± 0.002 in.)
Inside diameter of ring at bottom	7 ± 0.3 cm. (2.75 ± 0.12 in.)
Inside diameter of ring at top	6 ± 0.3 cm. (2.36 ± 0.12 in.)
Height of ring	4 ± 0.1 cm. (1.57 ± 0.04 in.)
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm. at all points, shall not show a deviation at any point greater than 0.25 mm.

Temperature

3. The temperature of the air in the vicinity of the mixing slab, the dry ce-

ment, molds, and base plates shall be maintained between 20 and 27.5 C. (68 and 81.5 F.). The temperature of the mixing water shall not vary from 21 C. (70 F.) by more than plus or minus 1.7 C. (3 F.).

Procedure.

4. (*a*) *Preparation of Cement Paste.*—A 500-g. sample of cement shall be placed on a smooth, nonabsorbent surface and a crater formed in the center. A measured quantity of clean water shall be poured into the crater, and the cement on the outer edge shall be turned into the crater within 30 sec. by the aid of a trowel. After an additional interval of 30 sec. for the absorption of the water, during which interval the dry cement around the outside of the cone shall be lightly troweled over the remaining mixture to reduce the evaporation losses and to promote absorption, the operation shall be completed by continuous, vigorous mixing, squeezing, and kneading with the hands for 1½ min. During the operation of mixing, the hands shall be protected by snug-fitting rubber gloves.

(*b*) *Molding Test Specimen.*—The cement paste, prepared as described in Paragraph (*a*), shall be quickly formed into a ball with the gloved hands and tossed six times from one hand to the other, maintaining the hands about 6 in. apart. The ball, resting in the palm of one hand, shall be pressed into the larger end of the conical ring *G*, Fig. 1, held in the other hand, completely filling the ring with paste. The excess at the larger end shall then be removed by a single movement of the palm of the hand. The ring shall then be placed on its larger end on a glass plate *H*, and the excess paste at the smaller end sliced off at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring, and the top smoothed, if necessary, with a few light touches of the pointed end of the trowel. During these operations of cutting and smoothing, care shall be taken not to compress the paste.

(*c*) *Consistency Determination.*—The paste confined in the ring, resting on the plate, shall be centered under the rod *B*, Fig. 1, the plunger end *C* of which shall be brought in contact with the surface of the paste, and the setscrew *E* tightened. Then the movable indicator *F* shall be set to the upper zero mark of the scale, or an initial reading taken, and the rod released 30 sec. after completion of mixing. The apparatus shall be free of all vibrations during the test. The paste shall be of normal consistency when the rod settles to a point 10 mm. below the original surface in 30 sec. after being released. Trial pastes shall be made with varying percentages of water until the normal consistency is obtained. Each trial shall be made with fresh cement.

Calculation

5. The amount of water required for normal consistency shall be calculated as a percentage by weight of the dry cement.

Standard Method of Test for

SOUNDNESS OF HYDRAULIC CEMENT OVER BOILING WATER (PAT TEST)[1]

A.S.T.M. Designation: C 189 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 189; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the soundness of hydraulic cement by means of neat cement pats in steam at atmospheric pressure.

Apparatus

2. A steam apparatus in which the pats can be maintained in an atmosphere of saturated steam above boiling water, similar to that shown in Fig. 1, is recommended. The capacity of this apparatus may be increased by using a rack for holding the pats in a vertical or inclined position.

Test Specimen

3. A pat from cement paste of normal consistency,[3] about 3 in. in diameter, $\frac{1}{2}$ in. in thickness at the center, and tapering to a thin edge, shall be made on a flat, clean glass plate about 4 in. square. In molding the pat, the cement paste shall first be flattened on the glass and the pat then formed by drawing the trowel from the outer edge toward the center to give a rounded surface.

Procedure

4. (*a*) Immediately after being made, the pats shall be stored for 24 hr. in an atmosphere of not less than 98 per cent relative humidity at 70 ± 3 F. The pat on the glass plate shall then be placed in an atmosphere of saturated steam on a suitable support 1 in. above boiling water for 5 hr.

(*b*) The pat shall be examined for soundness within 1 hr. after removal from the steam apparatus. Unsoundness is usually manifested by change in volume, which causes distortion, cracking, checking, or disintegration as illustrated in Fig. 2 (*b*).

(*c*) Should the pat leave the plate, distortion may be detected best with a straightedge applied to the surface that was in contact with the plate.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] This method formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 – 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

Standard Method of Test for

SPECIFIC GRAVITY OF HYDRAULIC CEMENT[1]

A.S.T.M. Designation: C 188 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 188; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the specific gravity of hydraulic cement. Its particular usefulness is in connection with the design and control of concrete mixtures.

Apparatus

2. (*a*) The standard Le Chatelier flask[3] conforming to the dimensions shown in Fig. 1 shall be used.

(*b*) Kerosine free of water, or naphtha having a gravity not lighter than 62° A.P.I. shall be used in the specific gravity determination.

Procedure

3. (*a*) Specific gravity of cement shall be determined on the material as received, unless otherwise specified. If the specific gravity determination on a loss-free sample is required, the sample shall first be ignited as described in the test for loss on ignition in Section 17 of the Standard Methods of Chemical Analysis of Portland Cement (A.S.T.M. Designation: C 114).[4]

(*b*) The flask shall be filled (Note 1) with either of the liquids specified in Section 2 (*b*) to a point on the stem between the zero and the 1-ml. mark. The inside of the flask above the level of the liquid shall be dried, if necessary, after pouring. The first reading shall be recorded after the flask has been immersed in the water bath (Note 2) in accordance with Paragraph (*c*). A weighed quantity of cement (about 64 g. for portland cement) shall then be introduced in small amounts at the same temperature as the liquid (Note 1). Care shall be taken to avoid splashing and to see that the cement does not adhere to the inside of the flask above the liquid. A vibrating apparatus may be used to accelerate the introduction of the cement into the flask

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] This method formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 – 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

[3] This apparatus has been standardized by the National Bureau of Standards. Requirements for the flask are described in "Testing of Glass Volumetric Apparatus," Nat. Bureau Standards, *Circular C434*, Superintendent of Documents, Government Printing Office, Washington, D. C. (1941).

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

and to prevent the cement from sticking to the neck. After all the cement has been introduced, the stopper shall be placed in the flask and the flask rolled in an inclined position (Note 1), or gently whirled in a horizontal circle, so as to free the cement from air until no further air bubbles rise to the surface of the liquid. If a proper amount of cement has been added, the level of the liquid will be in its final position at some point of the upper series of graduations. The final reading shall be taken after the flask has been immersed in the water bath in accordance with Paragraph (*c*).

NOTE 1.—It is advisable to use a rubber pad on the table top when filling or rolling the flask.

NOTE 2.—Before the cement has been added to the flask, a loose-fitting lead-ring weight around the stem of the flask will be helpful in holding the flask in an upright position in the water bath, or the flask may be held in the water bath by a burette clamp.

(*c*) The flask shall be immersed in a constant-temperature water bath, maintained at about room temperature, for a sufficient interval before making either of the readings so as to avoid variations greater than 0.2 C. in the temperature of the liquid in the flask. All readings shall be checked until they are constant to ensure that the contents of the flask have reached the temperature of the water bath.

Calculation

4. The difference between the first and the final readings represents the volume of liquid displaced by the weight of cement used in the test. The specific gravity shall be calculated as follows:

$$\text{Sp. gr.} = \frac{\text{wt. of cement in grams}}{\text{displaced vol. in ml.}}$$

Reproducibility

5. Duplicate determinations of specific gravity by this method should agree within 0.01.

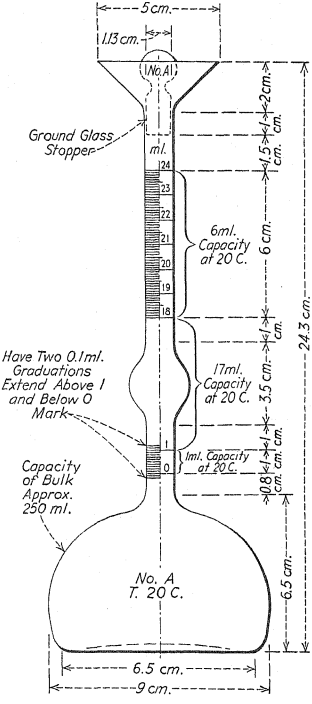

FIG. 1.—Le Chatelier Flask for Specific Gravity Test.

NOTE.—Variations of a few millimeters in such dimensions as total height of flask, diameter of base, etc., are to be expected and will not be considered sufficient cause for rejection.

Standard Methods of Test for

TIME OF SETTING OF HYDRAULIC CEMENT BY THE VICAT OR GILLMORE NEEDLES[1]

A.S.T.M. Designation: C 191 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 191; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test are intended for determining the time of setting of hydraulic cement by means of the Vicat or Gillmore needles.

NOTE.—The Vicat method and the Gillmore method are alternate procedures, either of which may be used as specified.

Apparatus

2. (*a*) *Scales.*—The scales shall conform to the following requirements: On scales in use the permissible variation at a load of 1000 g. shall be plus or minus 1.0 g. The permissible variation on new scales shall be one half of this value. The sensibility reciprocal[3] shall be not greater than twice the permissible variation.

(*b*) *Weights.*—The permissible variations on weights in use in weighing the cement shall be as prescribed in Table I. The permissible variations on new weights shall be one half of the values in Table I.

TABLE I.—PERMISSIBLE VARIATIONS ON WEIGHTS.

(*c*) *Glass Graduates.*—Glass graduates of 100-ml. to 200-ml. capacities used for measuring the mixing water shall be made to deliver the indicated volume at 20 C. (68 F.). The permissible variation shall be plus or minus 1.0 ml. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] These methods formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 – 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

[3] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

way around, and intermediate graduations shall extend at least one fifth of the way around.

(*d*) *Vicat Apparatus.*—The Vicat apparatus shall consist of a frame *A* (Fig. 1) bearing a movable rod *B*, weighing 300 g., one end *C*, the plunger end, being 1 cm. in diameter for a distance of at least 5 cm., and the other end having a removable needle *D*, 1 mm. in diameter and 5 cm. in length. The rod *B* is reversible, and can be held in any desired position by a set screw *E*, and has an adjustable indicator *F* which moves over a scale (graduated in millimeters) attached to the frame *A*. The paste is held in a rigid conical ring *G*, resting on a glass plate *H* about 10 cm. square. The ring shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 7 cm. at the base and 6 cm. at the top, and a height of 4 cm. In addition to the above, the Vicat apparatus shall conform to the following requirements:

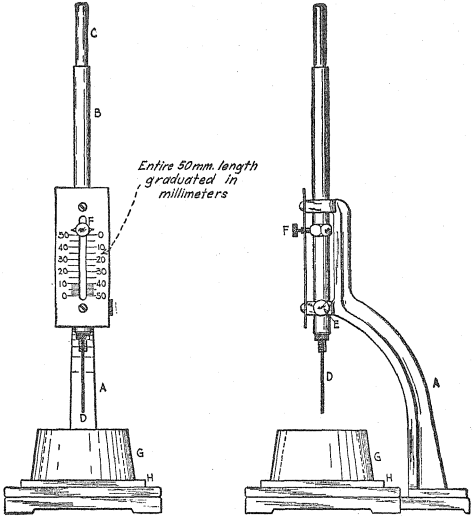

FIG. 1.—Vicat Apparatus.

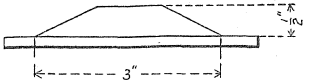
Weight of plunger	300 ± 0.5 g. (0.661 lb. ± 8 grains)
Diameter of larger end of plunger	1 ± 0.005 cm. (0.394 ± 0.002 in.)
Diameter of needle	1 ± 0.05 mm. (0.039 ± 0.002 in.)
Inside diameter of ring at bottom	7 ± 0.3 cm. (2.75 ± 0.12 in.)
Inside diameter of ring at top	6 ± 0.3 cm. (2.36 ± 0.12 in.)
Height of ring	4 ± 0.1 cm. (1.57 ± 0.04 in.)
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm. at all points, shall not show a deviation at any point greater than 0.25 mm.

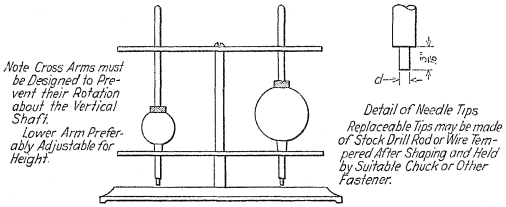
(*e*) *Gillmore Needles.*—The Gillmore needles shall conform to the following requirements:

Initial Needle:	
Weight	¼ lb. ± 8 grains (113.4 ± 0.5 g.)
Diameter	1/12 ± 0.002 in. (2.12 ± 0.05 mm.)
Final Needle:	
Weight	1 lb. ± 8 grains (453.6 ± 0.5 g.)
Diameter	1/24 ± 0.002 in. (1.06 ± 0.05 mm.)



The needle tips shall be cylindrical for a distance of about 1/16 in. The needle ends shall be plane and at right angles to the axis of the rod and shall be maintained in a clean condition. The Gillmore needles should preferably be mounted as shown in Fig. 2 (*b*).

Temperature and Humidity



3. The temperature of the air in the vicinity of the mixing slab, the dry cement, molds, and base plates shall be maintained between 20 and 27.5 C. (68 and 81.5 F.). The temperature of the mixing water and of the moist closet or moist room shall not vary from 21 C. (70 F.) by more than plus or minus 1.7 C. (3 F.) The moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 90 per cent.

Preparation of Cement Paste

4. A 500-g. sample of cement shall be placed on a smooth, nonabsorbent surface and a crater formed in the center. The percentage of clean water required for normal consistency[4] shall be poured into the crater, and the cement on the outer edge shall be turned into the crater within 30 sec. by the aid of a trowel. After an additional interval of 30 sec. for the absorption of the water, during which interval the dry cement around the outside of the cone shall be lightly troweled over the remaining mixture to reduce the evaporation losses and to promote absorption, the operation shall be completed by continuous, vigorous mixing, squeezing, and kneading with the hands for 1½ min. During the operation of mixing, the hands shall be protected by snug-fitting rubber gloves.

(*b*) Gillmore Needles.

FIG. 2.—Gillmore Apparatus and Test Specimen.

[4] Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure for Vicat Method

5. (*a*) *Molding Test Specimen.*—The cement paste, prepared as described in Section 4, shall be quickly formed into a ball with the gloved hands and tossed six times from one hand to the other, maintaining the hands about 6 in. apart. The ball, resting in the palm of one hand, shall be pressed into the larger end of the conical ring *G*, Fig. 1, held in the other hand, completely filling the ring with paste. The excess at the larger end shall then be removed by a single movement of the palm of the hand. The ring shall then be placed on its larger end on a glass plate *H*, and the excess paste at the smaller end sliced off at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring, and the top smoothed, if necessary, with a few light touches of the pointed end of the trowel. During these operations of cutting and smoothing, care shall be taken not to compress the paste. Immediately after molding, the test specimen shall be placed in the moist closet or moist room and remain there except when the determinations of time of setting are being made. The test specimens shall remain in the conical mold, supported by the plate *H*, throughout the test period.

(*b*) *Time of Setting Determination.*—The needle *D* of the rod *B*, Fig. 1, shall be lowered until it rests on top of a portion of the glass plate which projects beyond the ring *G*, and the adjustable indicator *F* set to the lower zero mark of the scale or an initial reading taken. The rod *B* shall then be raised, the needle *D* carefully brought in contact with the surface of the paste, and the rod quickly released. The *initial set* shall be said to have occurred when the needle ceases to pass a point 5 mm. above the glass plate in 30 sec. after being released; and the *final set*, when the needle does not sink visibly into the paste.

(*c*) *Precautions.*—The test specimens shall be kept in the moist closet or moist room during the test. Care shall be taken to keep the needle clean, as the collection of cement on the sides of the needle retards the penetration, while cement on the point may increase the penetration. The time of setting is affected not only by the percentage and temperature of the water used and the amount of kneading the paste received, but also by the temperature and humidity of the air, and its determination is therefore only approximate.

Procedure for Gillmore Method

6. (*a*) *Molding Test Specimen.*—From the cement paste, prepared as described in Section 4, a pat about 3 in. in diameter and $\frac{1}{2}$ in. in thickness at the center with a flat top and tapering to a thin edge, Fig. 2 (*a*) shall be made on a flat, clean glass plate about 4 in. square. In molding the pat, the cement paste shall first be flattened on the glass and the pat then formed by drawing the trowel from the outer edge toward the center, then flattening the top. After making, the pat shall be placed in the moist closet or moist room and remain there except when the determinations of time of setting are being made.

(*b*) *Time of Setting Determination.*—In determining the time of setting, the needles shall be held in a vertical position and applied lightly to the surface of the pat. The cement shall be considered to have acquired its *initial set* when the pat will bear, without appreciable indentation, the Gillmore needle $\frac{1}{12}$ in. in diameter, loaded to weigh $\frac{1}{4}$ lb. The cement shall be considered to have acquired its *final set* when the pat will bear, without appreciable indentation, the Gillmore needle $\frac{1}{24}$ in. in diameter, loaded to weigh 1 lb.

(*c*) *Precautions.*—The appropriate precautions described in Section 5 (*c*) shall be observed.

Standard Method of Test for

TENSILE STRENGTH OF HYDRAULIC-CEMENT MORTARS[1]

A.S.T.M. Designation: C 190 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 190; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the tensile strength of hydraulic-cement mortars.

Apparatus

2. (*a*) *Scales.*—The scales used in weighing materials for the mortar mixes shall conform to the following requirements: On scales in use the permissible variation at a load of 1000 g. shall be plus or minus 1.0 g. and at a load of 1500 g. shall be plus or minus 2.0 g. The permissible variations on new scales shall be one half of these values. The sensibility reciprocal[3] shall be not greater than twice the permissible variation.

(*b*) *Weights.*—The permissible variations on weights in use in weighing materials for the mortar mixes shall be as prescribed in Table I. The permissible variations on new weights shall be one half of the values in Table I.

TABLE I.—PERMISSIBLE VARIATIONS ON WEIGHTS.

Weight, g.	Permissible Variations on Weights in Use, plus or minus, g.
1000	0.5
900	0.45
750	0.4
500	0.35
300	0.3
250	0.25
200	0.20
100	0.15
50	0.10
20	0.05
10	0.04
5	0.03
2	0.02
1	0.01

(*c*) *Sieves.*—Square-hole, woven wire cloth, No. 20 (840-micron) and No. 30 (590-micron) sieves conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11)[4] shall be used.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] This method formerly constituted a portion of the Standard Methods of Sampling and Physical Testing of Portland Cement (C 77 - 40), discontinued in 1944, which latter standard was originally part of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 9) published as standard from 1904 to 1930, at which time the specifications and methods were separated and published individually.

[3] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*d*) *Glass Graduates.*—Glass graduates of suitable capacities (preferably large enough to measure the mixing water in a single operation) shall be made to deliver the indicated volume at 20 C. (68 F.). The permissible variation shall be plus or minus 1.0 ml. These graduates shall be subdivided to at least 1 ml. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around.

(*e*) *Briquet Molds.*—The molds for making test specimens shall be made of metal not attacked by the cement mortar, and shall have sufficient material in the sides to prevent spreading during molding. Gang molds, when used, shall be of the type shown in Fig. 1. The

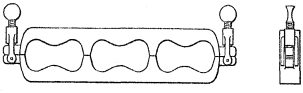

FIG. 1.—Briquet Gang Mold.

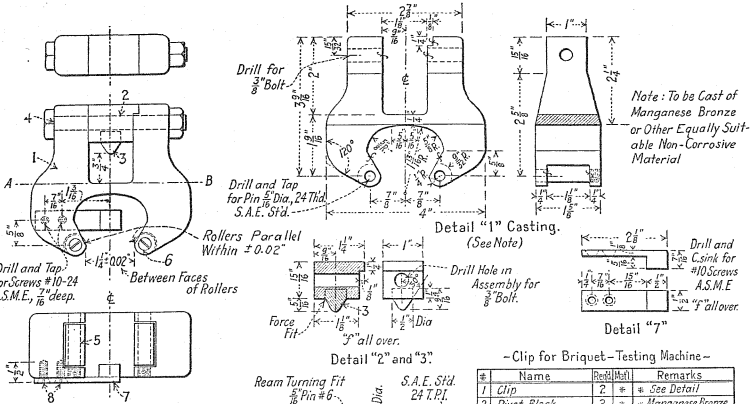
dimensions of the briquet molds shall conform to the following requirements: width of mold, between inside faces, at waist line of briquet, 1 in. with permissible variations of plus or minus 0.01 in. for old molds and plus or minus 0.005 in. for new molds; thickness of new molds measured at point of greatest thickness on either side of mold at waist line, 1 in. with permissible variations of plus 0.004 in. and minus 0.002 in.

(*f*) *Trowel.*—The trowel shall have a steel blade and be of convenient size.

(*g*) *Testing Machine.*—The testing machine shall be capable of applying the load continuously at a rate of 600 ± 25 lb. per min., with provision for adjustments of the rate of loading. The requirements for accuracy of the testing machine shall be as follows: The error for loads of not less than 100 lb. shall not exceed plus or minus 1.0 per cent for a new machine, or plus or minus 1.5 per cent for a used machine. The testing machine shall be calibrated frequently in order to determine its accuracy.

(*h*) *Clips.*—The clips for holding the tension test specimens shall be in accordance with Fig. 2.

Temperature and Humidity



3. The temperature of the air in the vicinity of the mixing slab, the dry materials, molds, and base plates shall be maintained between 20 and 27.5 C. (68 and 81.5 F.). The temperature of the mixing water, moist closet or moist room, and water in the briquet storage tank shall not vary from 21 C. (70 F.) by more than plus or minus 1.7 C. (3 F.). The moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 90 per cent.

Standard Sand

4. The sand used for making test specimens shall be natural silica sand from Ottawa, Ill., graded to pass a No. 20 (840-micron) sieve and retained on a No. 30 (590-micron) sieve. This sand shall be considered standard when not more than 15 g. are retained on the No. 20 sieve, and not more than 5 g. pass the No. 30 sieve after 5 min. of continuous sieving of a 100-g. sample in the manner specified for sieving cement in the Standard Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve (A.S.T.M. Designation: C 184).[4]

Test Specimens

5. The briquet test specimens shall conform to the dimensional requirements

FIG. 2.—Clips for Briquet Testing Machine.

shown in Fig. 3. Three or more specimens shall be made for each period of test specified.

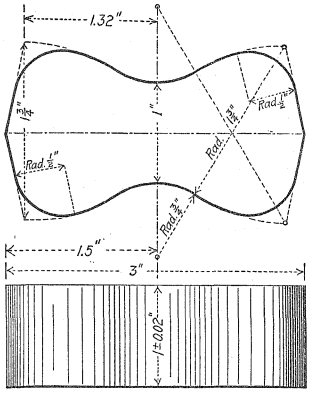

FIG. 3.—Briquet Specimen for Tensile Strength Test.

Proportioning, Consistency, and Mixing of Mortars

6. (*a*) The proportions of the standard mortar shall be 1 part cement to 3 parts standard sand by weight. The quantities of dry materials to be mixed at one time in the batch of mortar shall be not less than 1000 nor more than 1200 g. for making six briquets and not less than 1500 nor more than 1800 g. for making nine briquets. The percentage of water used in the standard mortar shall depend upon the percentage of water required to produce a neat cement paste of normal consistency from the same sample of cement and shall be as indicated in Table II, the values being in percentage of the combined dry weights of the cement and standard sand. The percentage of water required to produce a neat cement paste of normal consistency shall be determined in accordance with the Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187).[4]

(*b*) The dry materials shall be weighed, placed upon a smooth nonabsorbent surface, thoroughly mixed dry, and a crater formed in the center. The proper percentage of clean water shall be poured into the crater, and the material on the outer edge turned into the crater within 30 sec. by the aid of a trowel. After an additional interval of 30 sec. for the absorption of the water, during which interval the dry mortar around the outside of the cone shall be lightly troweled over the remaining mortar to reduce the evaporation losses and to promote absorption, the operation shall be completed by continuous, vigorous mixing,

TABLE II.—PERCENTAGE OF WATER FOR STANDARD MORTARS.

Percentage of Water for Neat Cement Paste of Normal Consistency	Percentage of Water for Mortar of One Part Cement to Three Parts Standard Sand[a]
15	9.0
16	9.2
17	9.3
18	9.5
19	9.7
20	9.8
21	10.0
22	10.2
23	10.3
24	10.5
25	10.7
26	10.8
27	11.0
28	11.2
29	11.3
30	11.5

[a] When the proportions of cement to sand are other than one to three by weight, the amount of mixing water shall be calculated from the following formula, upon which Table II is based:

$$y = \tfrac{3}{4}\frac{P}{n+1} + K$$

where:

y = percentage of water required for the sand mortar,
P = percentage of water required for neat cement paste of normal consistency,
n = number of parts of sand to one of cement by weight, and
K = a constant which for the standard sand has the value 6.5.

squeezing, and kneading with the hands for 1½ min. During the operation of mixing, the hands shall be protected by snug-fitting rubber gloves.

Molding Test Specimens

7. Before being filled, the molds shall be thinly covered with a film of mineral oil. Immediately following completion of mixing the mortar, the molds, resting on unoiled glass or metal plates, shall be filled heaping full without compacting. The mortar shall then be pressed in firmly with the thumbs, applying the force 12 times to each briquet, at points to include the entire surface. The force shall be such that the simultaneous application of both thumbs will register a force of 15 to 20 lb. Each application of the thumbs shall be maintained not longer than sufficient to attain the specified force. The mortar shall then be heaped above the mold and smoothed off with a trowel. The trowel shall be drawn over the mold in such a manner as to exert a force of not more than 4 lb. The mold shall then be covered with a plane glass or metal plate oiled with mineral oil, and the mold and plates (held together with the hands) shall then be turned over, rotating the mold about its longitudinal axis. The top plate shall then be removed and the operation of heaping, thumbing, heaping, and smoothing off shall be repeated. No ramming or tamping shall be used, nor any troweling in excess of that required to smooth off the specimen.

Storage of Test Specimens

8. All test specimens, immediately after molding, shall be kept in the molds on the base plates in the moist closet or moist room for from 20 to 24 hr. with their upper surfaces exposed to the moist air but protected from dripping water. If removed from the molds before 24 hr., they shall be kept on the shelves of the moist closet or moist room until they are 24 hr. old, when the specimens, except those for the 24-hr. test, shall be immersed in clean water in storage tanks constructed of noncorroding materials. The storage water shall be kept clean by frequent changing.

Procedure

9. (*a*) The briquet specimens shall be tested immediately after their removal from the moist closet for 24-hr. specimens, and from storage water for all other specimens. If more than one specimen at a time is removed from the moist closet for the 24-hr. tests, these briquets shall be covered with a damp cloth until time of testing. If more than one specimen at a time is removed from the storage water for testing, these briquets shall be placed in a pan of water at a temperature of 21 ± 1.7 C. (70 ± 3 F.) and of sufficient depth to completely immerse each briquet until time of testing.

(*b*) Each briquet shall be wiped to a surface-dry condition, and any loose sand grains or incrustations shall be removed from the surfaces that will be in contact with the clips of the testing machine. The bearing surfaces of the clips shall be clean and free of sand, and the roller bearings shall be well oiled and maintained so as to insure freedom of turning. The stirrups supporting the clips shall be kept free of accumulations, and the pivots shall be kept in proper adjustment so that the clips may swing freely on the pivots without binding in the stirrups. The briquets shall be carefully centered in the clips and the load applied continuously at the rate of 600 ± 25 lb. per min.

Faulty Briquets and Retests

10. Briquets that upon removal from the molds do not conform to the requirements for thickness and width at the waist line (Fig. 3), or that are mani-

festly faulty, or that give strengths differing by more than 15 per cent from the average value of all test specimens made from the same sample and tested at the same period, shall not be considered in determining the tensile strength (Note). After discarding briquets or strength values, if less than two strength values are left for determining the tensile strength at any given period, a retest shall be made.

NOTE.—Reliable strength results depend upon careful observance of all of the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the briquets, as prescribed in Section 9 (*b*).

Standard Method of Test for

COMPRESSIVE STRENGTH OF HYDRAULIC-CEMENT MORTARS[1]

A.S.T.M. Designation: C 109 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 109; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the compressive strength of hydraulic-cement mortars.

Apparatus

2. (*a*) *Scales.*—The scales used in weighing materials for mortar mixes shall conform to the following requirements: On scales in use the permissible variation at a load of 2000 g. shall be plus or minus 2.0 g. The permissible variation on new scales shall be one half of this value. The sensibility reciprocal[3] shall be not greater than twice the permissible variation.

(*b*) *Weights.*—The permissible variations on weights in use in weighing materials for mortar mixes shall be as prescribed in Table I. The permissible variations on new weights shall be one half of the values in Table I.

TABLE I.—PERMISSIBLE VARIATIONS ON WEIGHTS.

Weight, g.	Permissible Variations on Weights in Use, plus or minus, g.
1000	0.5
900	0.45
750	0.4
500	0.35
300	0.3
250	0.25
200	0.20
100	0.15
50	0.10
20	0.05
10	0.04
5	0.03
2	0.02
1	0.01

(*c*) *Sieves.*—Square-hole, woven wire cloth No. 100 (149-micron), No. 50 (297-micron), No. 30 (590-micron) and No. 16 (1190-micron) sieves conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11)[4] shall be used.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-1 on Cement.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1944, being revised in 1937, 1943, and 1944.

[3] The sensibility reciprocal is a measure of the sensitiveness of a balance, and is the weight required to move the position of equilibrium of the pointer one division. For a complete definition of sensibility reciprocal, see "Specifications, Tolerances, and Regulations for Commercial Weighing and Measuring Devices," *Handbook H29*, Nat. Bureau Standards, September, 1942, pp. 87 and 88.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*d*) *Glass Graduates.*—Glass graduates of suitable capacities (preferably large enough to measure the mixing water in a single operation) shall be made to deliver the indicated volume at 20 C. (68 F.). The permissible variation shall be plus or minus 2 ml. These graduates shall be subdivided to at least 5 ml. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around.

(*e*) *Specimen Molds.*—Molds for the 2-in. cube test specimens shall be tight fitting. The parts of the molds when assembled shall be positively held together. The molds shall be made of hard metal not attacked by the cement mortar. For new molds the Rockwell hardness number of the metal shall be not less than B 55. There shall be sufficient material in the sides of the molds to prevent spreading or warping. The interior faces of the molds shall be plane surfaces with a permissible variation of 0.001 in. for new molds and 0.002 in. for molds in use. The distances between opposite faces shall be 2 ± 0.005 in. for new molds, and 2 ± 0.02 in. for molds in use. The height of the molds, measured separately for each cube compartment, shall be 2 in. with permissible variations of plus 0.01 in. and minus 0.005 in. for new molds, and plus 0.01 in. and minus 0.015 in. for molds in use. The angle between adjacent interior faces, and between interior faces and top and bottom planes of the mold shall be 90 ± 0.5 deg. measured at points slightly removed from the intersection of the faces.

(*f*) *Mixing Bowl.*—The mixing bowl shall be of enamelware or other nonabsorptive, noncorroding material and shall have a capacity of 6 to 8 qt.

(*g*) *Flow Table.*—The flow table apparatus shall consist of a rigid metal frame and a circular rigid table 10 in. in diameter with a shaft attached perpendicular to the table top. The table with attached shaft shall be mounted on the frame in such a manner that it can be raised and dropped vertically through a fixed height of ½ in. by means of a rotated cam. The table top shall have a plane surface and be of noncorrodible metal. The table and the attached shaft shall weigh 9 ± 0.1 lb. The end of the shaft shall not strike upon the cam at the end of the drop. The surfaces of the table and the frame which come into contact at the end of the drop shall be plane and parallel with the upper surface of the table and the material of these parts shall be hard metal to prevent cushioning effect. The contact faces of the cam and the shaft shall be such that the table does not rotate more than one revolution during the 25 drops. The frame shall be attached rigidly to a concrete pedestal which shall be attached rigidly to the floor. The concrete pedestal shall be at least 8 in. square or in diameter at the top and at least 25 in. in height with a base suitable for rigid attachment to the floor and shall weigh at least 100 lb. The table top, after the frame has been mounted on the pedestal, shall be level along any two diameters at right angles to each other in both the raised and the lowered position.

(*h*) *Flow Mold.*—The flow mold shall be made of noncorrodible material and shall be 4 in. in inside diameter at the base, 2.75 in. in inside diameter at the top, and 2 in. in height.

(*i*) *Tamper.*—The tamper shall be made of a nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak wood rendered nonabsorptive by immersion for 15 min. in paraffin at approximately 200 C. (392 F.), and shall have a cross-section of ½ by 1 in. and a convenient length (5 or 6 in.).

(*j*) *Trowel.*—The trowel shall have a steel blade 4 to 6 in. in length, with straight edges.

(*k*) *Testing Machine.*—The testing machine may be either the hydraulic or the screw-type with sufficient opening between the upper bearing surface and the lower bearing surface of the machine to permit the use of verifying apparatus. The load applied to the test specimen shall be indicated with an accuracy of plus or minus 1.0 per cent. The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to turn in any direction. The diagonal or diameter[5] of the bearing surface shall be only slightly greater than the diagonal of the face of the 2-in. cube in order to facilitate accurate centering of the specimen. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. The bearing block surfaces intended for contact with the specimen shall have a Rockwell hardness number not less than C 60. These surfaces shall not depart from plane surfaces by more than 0.0005 in. when the blocks are new and shall be maintained within a permissible variation of 0.001 in.

Temperature and Humidity

3. The temperature of the air in the vicinity of the mixing slab, the dry materials, molds, base plates, and mixing bowl, shall be maintained between 20 and 27.5 C. (68 and 81.5 F.). The temperature of the mixing water, moist closet or moist room, and water in the storage tank shall not vary from 21 C. (70 F.) by more than plus or minus 1.7 C. (3 F.). The moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 90 per cent.

Graded Standard Sand

4. The sand (Note 1) used for making test specimens shall be natural silica sand from Ottawa, Ill., graded as follows:

Sieve	Percentage Retained
No. 100 (149-micron)	98 ± 2
No. 50 (297-micron)	72 ± 5
No. 30 (590-micron)	2 ± 2
No. 16 (1190-micron)	none

Sieve Analysis of Sand

5. (*a*) For checking the grading of the sand, a sieving test of the sand shall be made on each of the four sieves specified in Section 2 (*c*). Samples of sand for the sieve tests shall be quartered from a sample of about 700 g. obtained by the method of quartering the contents of a full sack (100 lb.) which have been thoroughly mixed and the pile flattened or spread out to minimize segregation during quartering.

(*b*) The test on each sieve shall be made with 100 g. of sand. The sieve shall be thoroughly clean and dry. The sieving operation shall be performed in the manner specified for sieving cement in the Standard Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve (A.S.T.M. Designation: C 184),[4] except that sieving shall be continued until not more than 0.5 g. passes through in 1 min. of continuous sieving. The weight of the residue on the sieve shall be expressed as a percentage of the weight of the original sample.

[5] A diameter of 3⅛ in., which is large enough for testing 3 by 6-in. cylinders, is satisfactory provided that the lower bearing block has a diameter slightly greater than the diagonal of the face of the 2-in. cube but not more than 2.9 in., and is centered with respect to the upper bearing block and held in position by suitable means.

Number of Specimens

6. Three or more specimens shall be made for each period of test specified.

Preparing Specimen Molds

7. The interior faces of the specimen molds shall be thinly covered with mineral oil or light cup grease. The contact surfaces of the halves of each mold shall be thinly covered with a heavy mineral oil or light cup grease such as petrolatum. After assembling the molds, excess oil or grease shall be removed from the interior faces and the top and bottom surfaces of each mold. Molds shall then be set on plane, nonabsorptive base plates which have been thinly coated with mineral oil, petrolatum, or light cup grease. A mixture of 3 parts of paraffin to 5 parts of rosin by weight, heated between 110 and 120 C. (230 and 248 F.), shall be applied at the outside contact lines of the molds and base plates so that watertight joints are effected between the molds and the base plates (Note 2).

Proportioning, Consistency, and Mixing of Mortars

8. (*a*) The proportions of dry materials of the standard mortar shall be one part of cement to 2.75 parts of graded standard sand by weight. The quantities of dry materials to be mixed at one time in the batch of mortar for making six cubes shall be 500 g. of cement and 1375 g. of graded standard sand. The quantities of dry materials to be mixed at one time in the batch of mortar for nine cubes shall be 700 g. of cement and 1925 g. of graded standard sand. The amount of mixing water, measured in milliliters, shall be such as to produce a flow of between 100 and 115 as determined in accordance with Section 9 and shall be expressed as a percentage by weight of the cement.

(*b*) Mixing shall be done in a bowl (Section 2 (*f*)) by vigorous and continuous stirring, squeezing, and kneading with one hand which shall be protected by a snug-fitting rubber glove. The materials for a batch shall be introduced in the following manner:

(*1*) Place the water in the bowl, which has just been wiped with a damp cloth or damp sponge,

(*2*) Add the cement to the water and mix for 30 sec.,

(*3*) Add approximately one half of the testing sand and mix for 30 sec., and

(*4*) Add the remainder of the sand and mix for 1½ min.

Determination of Flow

9. The flow-table top shall be carefully wiped dry and the flow mold placed at the center. Immediately after completing the mixing operation, the mold shall be filled with mortar gently pressed into place by the finger tips to insure uniform filling. The mortar shall then be cut off to a plane surface, flush with the top of the mold, by drawing the straight edge of a trowel (held nearly perpendicular to the mold) with a sawing motion across the top of the mold. The mold shall be lifted away from the mortar 30 sec. after completing the mixing operation. Immediately the table shall be dropped through a height of ½ in., 25 times in 15 sec. The flow is the resulting increase in diameter of the mortar mass, expressed as a percentage of the original diameter. Trial mortars shall be made with varying percentages of water[6] until the specified flow is obtained. Each trial shall be made with fresh mortar. The batch of mortar upon which flow has been determined shall not be used for molding specimens.

---

[6] As a guide for the initial trial mortar, the percentage of water to produce the specified flow will be about 53 per cent for portland cement containing air-entraining material and about 55 per cent for portland cement not containing air-entraining material.

Molding Test Specimens

10. Immediately following completion of the mixing, the mortar adhering to the mixing glove shall be removed by striking the hand against the side or edge of the mixing bowl. The glove shall then be removed. A layer of mortar about 1 in. in thickness shall be placed in all of the cube compartments. Then the mortar in each cube compartment shall be tamped (Section 2 (*i*)) 32 times in about 10 sec. in four rounds, each round to be at right angles to the other and consisting of eight adjoining strokes over the surface of the specimen, as illustrated in Fig. 1. The tamping pressure shall be just sufficient to insure uniform filling of the molds. The four rounds of tamping (32 strokes) of the mortar shall be completed in one cube before going to the next. When the tamping of the first layer in all of the cube compartments is completed, the compartments shall be filled with the remaining mortar and then tamped as specified for the first layer. On completion of the tamping, the tops of all cubes should extend slightly above the tops of the molds. The mortar which has been forced out onto the tops of the molds shall be brought in with a trowel and the cubes smoothed off by drawing the flat side of the trowel (with the leading edge slightly raised) once across the top of each cube at right angles to the length of the mold. The mortar shall then be cut off to a plane surface flush with the top of the mold by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion over the length of the mold.

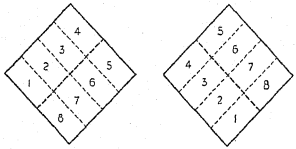

FIG. 1.—Order of Tamping in Molding of Test Specimens.

Storage of Test Specimens

11. All test specimens, immediately after molding, shall be kept in the molds on the base plates in the moist closet or moist room from 20 to 24 hr. with their upper surfaces exposed to the moist air but protected from dripping water. If removed from the molds before 24 hr., they shall be kept on the shelves of the moist closet or moist room until they are 24 hr. old, when the specimens, except those for the 24-hr. test, shall be immersed in clean water in storage tanks constructed of noncorroding materials. The storage water shall be kept clean by frequent changing.

Procedure

12. (*a*) Testing of the cube specimens shall be carried out immediately after their removal from the moist closet for 24-hr. specimens, and from storage water for all other specimens. If more than one specimen at a time is removed from the moist closet for the 24-hr. tests, these cubes shall be covered with a damp cloth until time of testing. If more than one specimen at a time is removed from the storage water for testing, these cubes shall be placed in a pan of water at a temperature of 21 ± 1.7 C. (70 ± 3 F.) and of sufficient depth to completely immerse each cube until time of testing.

(*b*) Each cube shall be wiped to a surface-dry condition, and any loose sand grains or incrustations shall be removed from the faces that will be in contact with the bearing blocks of the testing

machine. These faces shall be checked by application of a straightedge (Note 3). If appreciable curvature is present, the face or faces shall be ground to plane surfaces or the specimen shall be discarded.

(*c*) The load shall be applied to cube faces that were in contact with the true plane surfaces of the mold. The cube shall be carefully placed in the testing machine below the center of the upper bearing block. No cushioning or bedding materials shall be used. The loading up to 50 per cent (25 per cent for expected maximum loads of less than 4000 lb. at ages of 7 days or less) of the expected maximum load may be applied at any convenient rate, after which the specimen shall be loaded continuously to failure at a rate or rates which shall at no time be less than 1000 nor more than 6000 psi. per min.[7]

Calculation

13. The total maximum load indicated by the testing machine shall be recorded, and the compressive strength calculated in pounds per square inch. If the cross-sectional area of a cube varies more than 0.06 sq. in. from 4.00 sq. in., the actual area shall be used for the calculation of the compressive strength.

Faulty Cubes and Retests

14. Cubes that are manifestly faulty, or that give strengths differing by more than 10 per cent from the average value of all test specimens made from the same sample and tested at the same period, shall not be considered in determining the compressive strength (Note 4). After discarding cubes or strength values, if less than two strength values are left for determining the compressive strength at any given period, a retest shall be made.

EXPLANATORY NOTES

NOTE 1: *Segregation of Graded Sand.*—The graded standard sand should be handled in such a manner as to prevent segregation, since variations in the grading of the sand cause variations in the consistency of the mortar. In emptying sacks of sand into bins or in scooping sand out of bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

NOTE 2: *Watertight Molds.*—The mixture of paraffin and rosin specified for sealing the joints between molds and base plates may be found difficult to remove when molds are being cleaned. Use of straight paraffin is permissible if a watertight joint is secured, but due to the low strength of paraffin it should be used only when the mold is not held to the base plate by the paraffin alone. A watertight joint may be secured with paraffin alone by slightly warming the mold and base plate before brushing the joint. Molds so treated should be allowed to return to the specified temperature before use.

NOTE 3: *Cube Faces.*—Results much lower than the true strength will be obtained by loading faces of the cube which are not truly plane surfaces. Therefore, it is essential that cube molds be kept scrupulously clean, as otherwise large irregularities in the surfaces will occur. Instruments for cleaning of molds should always be softer than the metal in the molds to prevent wear. In case grinding of cube faces is necessary, it can be accomplished best by rubbing the cube on a sheet of fine emery paper or cloth glued to a plane surface,

[7] While the data presented in the report of the 1933 cooperative tests (see the Report of Working Committee on Plastic Mortar Tests for Portland Cement, of Committee C-1 on Cement, *Proceedings*, Am. Soc. Testing Mats., Vol. 34, Part I, p. 322 (1934)) do not give conclusive evidence on effect of rate of loading, the Working Committee favors the use of a uniform rate of loading of about 4000 psi. per min. (1000 psi. per min. for low-heat portland cements at ages of 7 days or less).

using only a moderate pressure. Such grinding is tedious for more than a few thousandths of an inch; where more than this is found necessary, it is recommended that the cube be discarded.

NOTE 4.—Reliable strength results depend upon careful observance of all of the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the cubes as prescribed in Section 12 (*b*) and (*c*). Improper centering of cubes resulting in oblique fractures or lateral movement of one of the heads of the testing machine during loading will often cause lower strength results. A cube so broken shall be considered as "manifestly faulty" if its strength differs by more than 10 per cent from the average of all test specimens made from the same sample and tested at the same period.

Standard Specifications for
QUICKLIME FOR STRUCTURAL PURPOSES[1]

A.S.T.M. Designation: C 5 - 26

ADOPTED, 1926.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 5; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover all classes of quicklime, such as crushed lime, granular lime, ground lime, lump lime, pebble lime, and pulverized lime, used for structural purposes.

Chemical Composition

2. The quicklime shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

	Calcium Lime	Magnesium Lime
Calcium oxide, min., per cent	75	..
Magnesium oxide, min., per cent	..	20
Calcium and magnesium oxides, min., per cent	95	95
Silica, alumina, and oxide of iron, max., per cent	5	5
Carbon dioxide, max., per cent:		
If sample is taken at the place of manufacture	3	3
If sample is taken at any other place	10	10

Residue

3. The quicklime shall contain not more than 15 per cent by weight of residue.

Sampling, Inspection, etc.

4. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Chemical Analysis.*—Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25).[3]

(*b*) *Physical Tests.*—Tentative Methods of Physical Testing of Quicklime and Hydrated Lime (A.S.T.M. Designation: C 110).[3]

---

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1913 to 1915, being revised in 1914 and 1915. They were adopted in 1915 but withdrawn and republished as tentative from 1921 to 1926, being revised in 1922 and 1924. Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPENDIX

Quicklime can never be used as such for structural purposes; it must always be slaked first. Since the method of slaking is an important factor in determining the quality of the finished product, the following directions for the preparation of lime putty are given, not as a part of the specifications, but as information for the further protection of the purchaser.

A1. *Introduction.*—Different kinds of lime vary considerably in the way in which they behave with water. A little supervision over the operation of slaking will amply pay for itself by insuring the production of the greatest possible quantity and the best possible quality of putty. To find out how to slake a new lot of lime, it is safest to try a little of it and see how it works. Since different lots of the same brand of lime vary somewhat, and since the weather conditions at the time have a decided influence, it is wise to try a sample from each lot used, whether familiar with the brand or not.

A2. *Classification of Limes.*—In a bucket, put two or three lumps of lime about the size of one's fist, or, in the case of granular lime, an equivalent amount. Add sufficient water to just barely cover the lime, and note how long it takes for slaking to begin. Slaking has begun when pieces split off from the lumps or when the lumps crumble. Water of the same temperature should be used for test and field practice.

If slaking begins in less than 5 min., the lime is quick slaking; from 5 to 30 min., medium slaking; over 30 min., slow slaking.

A3. *Directions for Slaking.*—For quick-slaking lime, always add the lime to the water, not the water to the lime. Have sufficient water at first to cover all the lime completely. Have a plentiful supply of water available for immediate use—a hose throwing a good stream, if possible. Watch the lime constantly. At the slightest appearance of escaping steam, hoe thoroughly and quickly, and add enough water to stop the steaming. Do not be afraid of using too much water with this kind of lime.

For medium-slaking lime, add the water to the lime. Add enough water so that the lime is about half submerged. Hoe occasionally if steam starts to escape. Add a little water now and then if necessary to prevent the putty from becoming dry and crumbly. Be careful not to add any more water than required, and not too much at a time.

For slow-slaking lime, add enough water to the lime to moisten it thoroughly. Let it stand until the reaction has started. Cautiously add more water, a little at a time, taking care that the mass is not cooled by the fresh water. Do not hoe until the slaking is practically complete. If the weather is very cold, it is preferable to use hot water, but if this is not available, the mortar box may be covered in some way to retain the heat.

A4. *Preparation of Putty for Use.*—After slaking, the putty shall be prepared for use, as follows:

(*a*) *White Coat.*—After the action has ceased, run off the putty through a No. 10 (2000-micron) sieve and store for a minimum of two weeks.

(*b*) *Base Coats.*—After the action has ceased, run off the putty through a No. 8 (2380-micron) sieve. Add sand up to equal parts by weight, all of the hair required, and store for a minimum of two weeks.

(*c*) *Masons' Mortar.*—After the action has ceased, add part or all of the sand required, and store for a minimum of 24 hr.

Standard Specifications for

NORMAL FINISHING HYDRATED LIME[1]

A.S.T.M. Designation: C 6 – 44

ADOPTED, 1924; REVISED, 1931, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 6; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover one type of finishing hydrated lime which is suitable for use in the scratch, brown, and finish coats of plaster, for stucco, mortar, and as an addition to portland-cement concrete. Lime sold under these specifications shall be designated type N—normal finishing hydrate.

Chemical Composition

2. Type N—normal finishing hydrate shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

Calcium and magnesium oxides, min., per cent	95
Carbon dioxide, max., per cent:	
If sample is taken at the place of manufacture	5
If sample is taken at any other place	7

Residue

3. The percentage residue of type N—normal finishing hydrate shall conform to the following requirements:

Residue retained on No. 30 (590-micron) sieve, max., per cent	0.5
Residue retained on No. 200 (74-micron) sieve, max., per cent	15

Soundness

4. Type N—normal finishing hydrate shall pass the test for soundness. If the steam has no visible effect on the pat, the sample shall be reported as being "sound." If the pat disintegrates, the sample shall be reported as being unsound and the shipment rejected. If the pat cracks, pops, or shows other minor defects, it shall not be reported as either sound or unsound, but its behavior shall be noted.

Plasticity

5. The putty made from type N—normal finishing hydrate shall have a plasticity figure of not less than 200 when soaked for a period of not less than 16 hr. nor more than 24 hr.

Sampling, Inspection, etc.

6. The sampling, inspection, rejection, retesting, packing, and marking

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1913 to 1915, being revised in 1914 and 1915. They were adopted in 1915, revised in 1919, but withdrawn and republished as tentative from 1921 to 1924, being revised in 1922, 1923, and 1924.

shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50).[2]

Methods of Testing

7. The properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Chemical Analysis.*—Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25).[2]

(*b*) *Physical Tests.*—Tentative Methods of Physical Testing of Quicklime and Hydrated Lime (A.S.T.M. Designation: C 110).[2]

[2] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

HYDRAULIC HYDRATED LIME FOR STRUCTURAL PURPOSES[1]

A.S.T.M. Designation: C 141 – 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 141; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover hydraulic hydrated lime for structural purposes.

(*b*) Hydraulic hydrated lime may be used for scratch or brown coat of plaster, for stucco, for mortar, and as sole cementitious material in concrete, or in portland-cement concrete either as blend, amendment, or admixture.

Definition

2. *Hydraulic Hydrated Lime.*—An hydraulic hydrated lime is the hydrated dry cementitious product obtained by calcining a limestone containing silica and alumina to a temperature short of incipient fusion so as to form sufficient free lime (CaO) to permit hydration and at the same time leaving unhydrated sufficient calcium silicates to give the dry powder, meeting the requirements herein prescribed, its hydraulic properties.

(*a*) High Calcium Hydraulic Hydrated Lime is a lime that contains not more than 5 per cent magnesium oxide (of the nonvolatile portion).

(*b*) Magnesium Hydraulic Hydrated Lime is a lime containing more than 5 per cent magnesium oxide (of the nonvolatile portion).

Chemical Composition

3. The hydraulic hydrated lime shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

	Minimum	Maximum
Calcium and magnesium oxides (CaO and MgO), per cent	60	70
Silica (SiO_2), per cent	16	26
Iron and aluminum oxides (Fe_2O_3 and Al_2O_3), per cent		12
Carbon dioxide (CO_2), per cent		5

Fineness

4. The sample shall leave a residue of not more than 0.5 per cent on a No. 30 (590-micron) sieve and not more than 10 per cent on a No. 200 (74-micron) sieve when tested as described in Section 18.

Time of Setting

5. The neat hydraulic hydrated lime

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1938 to 1942. Editorially revised in 1944.

paste mixed to normal consistency shall not develop an initial set in less than 2 hr. as determined by the Gillmore needle method. Final set shall be attained within 48 hr.

Soundness

6. Pats of neat hydraulic hydrated lime made and stored, as described in Section 21 shall be firm and hard and show no signs of distortion, cracking, or disintegration under both conditions of storage. Mortar strength specimens at the time of test shall show no signs of distortion, cracking, or disintegration.

Compressive Strength

7. The average compressive strength of not less than three 2-in cubes, made, stored, and tested in accordance with Sections 22 to 28, shall be not less than 175 psi. at the age of 7 days. The average strength attained at 28 days shall be not less than that attained at 7 days.

Packaging and Marking

8. The hydraulic hydrated lime shall be delivered in suitable containers with the brand and name of the manufacturer and the net weight plainly marked thereon. A bag shall contain 62.5 lb. net. A barrel shall contain 250 lb. net. All packages shall be in good condition at the time of inspection. Packages varying more than 10 per cent from the weight marked thereon may be rejected, and if the average weight of packages in any shipment, as shown by weighing 50 packages taken at random, is less than the weight marked thereon, the entire shipment may be rejected.

Storage

9. The hydraulic hydrated lime shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the hydraulic hydrated lime from damage.

Inspection

10. Every facility shall be provided the purchaser for sampling and inspection either at the place of manufacture or at the destination, as may be specified by the purchaser.

Rejection

11. The hydraulic hydrated lime may be rejected if it fails to meet any of the requirements of these specifications. However, hydraulic hydrated lime failing to meet the 7-day requirements may be held awaiting the result of the 28-day tests before rejection. At least ten days from the time of sampling shall be allowed for completion of the 7-day test, and at least thirty-one days shall be allowed for completion of the 28-day test.

SAMPLING AND METHODS OF TESTING

Size and Number of Samples

12. Each sample selected for purpose of tests shall weigh at least 5 lb. and shall represent not more than 200 bbl. If only one sample is taken it shall weigh at least 10 lb.

Shipment of Samples

13. Samples shall be shipped and stored in airtight, moistureproof containers.

Chemical Analysis

14. Analyses for chemical composition shall be carried out in accordance with the Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[3]

Standard Temperature

15. The standard temperature shall

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

be 70 F. (21 C.). The air of the laboratory, the materials, the mixing water, the moist closet, and storage tanks shall be maintained as nearly as practicable at the standard temperature and shall not vary therefrom more than 5 F. (3 C.).

Preliminary Treatment of Samples

16. The sample shall be given a preliminary sieving by being passed through a No. 20 sieve in order thoroughly to mix the sample, break up lumps, and remove foreign materials.

Fineness Test

17. (*a*) *Apparatus.*—The No. 30 (590-micron) and No. 200 (74-micron) sieves shall conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

(*b*) *Procedure.*—A 100-g. sample of the material as received shall be placed on a No. 30 sieve, which shall be nested above a No. 200 sieve. The material shall be washed by means of a stream of water from a faucet (Note 1). The washing shall be continued until the water coming through the sieve is clear, but in no case shall the washing be continued for more than 15 min. (Note 2). The residue on both sieves shall be dried to constant weight at a temperature between 212 and 248 F. (100 and 120 C.). The weights of material retained shall be calculated as a percentage of the original sample, the weight of the material retained on the No. 30 sieve being added to the weight of the material retained on the No. 200 sieve to obtain the correct weight of the material retained on the No. 200 sieve.

NOTE 1.—A piece of rubber tubing attached to a water faucet may be used for the washing. The velocity of the water, which may be increased by pinching the tubing, shall not be sufficient to cause any splashing of the sample over the sides of the sieve.

NOTE 2.—Care shall be taken not to let water accumulate on the No. 200 sieve, because the openings will become clogged and the operation cannot be completed in 15 min.

Mixing Paste[4]

18. Hydraulic hydrated lime pastes shall be mixed in accordance with Section 2 (*a*) to (*c*) and Section 4 (*a*) of the Standard Method of Test for Normal Consistency of Hydraulic Cement (A.S.T.M. Designation: C 187),[3] except that the operation of mixing, squeezing, and kneading with the hands shall be continued for 5 min.

Normal Consistency[4]

19. Normal consistency shall be determined by the Vicat apparatus in accordance with Standard Method C 187,[3] except that the mixing of the paste shall be performed in accordance with Section 18 of these specifications.

Time of Setting Test[4]

20. Time of setting shall be determined by the Gillmore needle method in accordance with the Standard Methods of Test for Time of Setting of Hydraulic Cement by the Vicat or Gillmore Needles (A.S.T.M. Designation: C 191),[3] except that the mixing of the paste shall be performed in accordance with Section 18 of these specifications. The hydraulic hydrated lime pats shall be stored during the test in a damp closet maintained at a relative humidity of 90 per cent or more.

Soundness Test

21. Two pats of hydraulic hydrated lime paste of normal consistency (Section 19) shall be used for making soundness tests. After the first 48 hr. in the damp closet one of the pats shall be stored in the air of the laboratory for 5 days and the other shall be immersed for 5 days in clean running water in storage tanks of suitable materials. Unsoundness is manifested by change in volume, which causes distortion, cracking, checking, or disintegration. Pats

[4] This section was editorially revised in 1944.

improperly made or exposed to drying may develop what is known as shrinkage cracks within the first 24 hr. The shrinkage cracks are not an indication of unsoundness. The mere failure of the pats to remain on the glass or the cracking of the glass to which the pats are attached do not indicate unsoundness. Should the pat leave the plate, distortion may be detected with a straightedge applied to the surface that was in contact with the plate, provided the glass plate was flat before test.

Compressive Strength Test

22. *Standard Sand.*[5]—The sand used for making test specimens shall be natural silica sand from Ottawa, Ill., graded to pass a No. 20 (840-micron) sieve and retained on a No. 30 (590-micron) sieve.[6] This sand shall be considered standard when not more than 15 g. are retained on the No. 20 sieve, and not more than 5 g. pass the No. 30 sieve after 5 min. of continuous sieving of a 100-g. sample in the manner specified for sieving cement in the Standard Method of Test for Fineness of Hydraulic Cement by the No. 200 Sieve (A.S.T.M. Designation: C 184).[3]

23. *Test Specimen.*—The compression test specimen shall be a 2-in. cube. The molds shall be of noncorrodible metal and shall be so designed as to prevent spreading during molding. Molds shall be oiled with a mineral oil before using.

24. (*a*) *Proportions for Standard Mortar.*[4]—The mortar shall consist of 1 part of hydraulic hydrated lime to 3 parts of standard Ottawa sand, by weight.

(*b*) *Preparation of Standard Mortar.*—The mortar shall be mixed in a nonabsorbent bowl of about 1-gal. capacity. A measured quantity of water shall be poured into the bowl which previously has been wiped with a damp cloth. A 500-g. sample of the hydraulic hydrated lime shall then be added and stirred into the water with the fingers of one hand until all of the hydraulic hydrated lime is wetted. Approximately 800 g. of sand shall then be added and the stirring continued for 30 sec. The remainder of 1500 g. of sand shall then be added and the mortar mixed for 75 sec. by vigorous and continued stirring, squeezing, and kneading with one hand. The mortar shall be allowed to stand for 60 sec. and then mixed for another 60 sec. During the operation of mixing, the hands shall be protected by rubber gloves. The top of the flow table (see Paragraph (*c*)) shall be carefully wiped dry and the flow mold placed at the center and filled with the mortar. In filling the mold the mortar shall not be rammed, but gently puddled to insure uniform filling. The mortar shall be smoothed off level with the top of the mold by aid of a trowel and the mold then removed. Immediately, the table shall be dropped through a height of ½ in., 25 times in 15 sec. The flow is the resulting increase in diameter of the mortar mass, expressed as a percentage of the original diameter. The mortar shall be of standard consistency when the flow is 100 to 115. Trial mortars shall be made with varying percentages of water until the standard consistency is obtained. Each trial shall be made with fresh mortar. The quantity of water shall be expressed as a percentage of the weight of the combined dry materials.

(*c*) *Flow Table.*—The flow table apparatus shall consist of a rigid frame with a flat circular top, so mounted on a vertical shaft that it can be raised and dropped ½ in. by means of a cam. The top shall be of noncorrodible metal,

[5] This section was added editorially in 1944.

[6] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

10 in. in diameter, and with the attached shaft shall weigh 9 lb. The mold shall be of noncorrodible material, 4 in. in inside diameter at the base, $2\frac{3}{4}$ in. in inside diameter at the top, and 2 in. in height.

25. *Molding of Test Specimens.*—The surfaces of the molds and plates to be in contact with the cube specimens shall be oiled with a medium viscosity oil. The molds shall be half filled with mortar, the mortar puddled into place with the finger tips of the gloved hand, the mold then filled to overflowing, and the mortar again puddled with the finger tips. The mortar shall then be troweled off flush with the top of the molds.

26. *Storage of Test Specimens.*—All test specimens, immediately after molding, shall be kept in the molds on plane plates in a damp closet, maintained at a relative humidity of 90 per cent or more, for from 48 to 52 hr. in such a manner that the upper surfaces shall be exposed to the moist air. The specimens shall then be removed from the molds and placed in the air of the laboratory for 5 days in such a manner as to allow free circulation of air around at least five faces of the specimens. At the age of 7 days the specimens for the 28-day tests shall be immersed in clean running water in storage tanks of noncorrodible materials.

27. *Testing of Specimens.*—The compressive strength test may be made with any type of verified compression testing machine of suitable capacity. Those faces of the cube specimen which when molded were in contact with the sides of the mold shall be placed in contact with the surfaces through which the load is applied. A spherical-seated bearing block shall be used between the upper face of the specimen and the head of the testing machine. The center of the sphere shall lie in that surface of the bearing block which is in contact with the specimen, and the radius of the sphere shall be $1\frac{1}{2}$ in. The specimen shall be carefully centered in the testing machine and below the center of the bearing block. Cushioning materials shall not be used. The load shall be applied uniformly and without shock. The moving head of the testing machine shall travel at the rate of approximately 0.05 in. per min. when the machine is running idle.

28. *Calculation of Compressive Strength.*—The total load indicated by the testing machine at failure of the test specimen shall be recorded, and the unit compressive strength calculated in pounds per square inch of the cross-sectional area of the specimen. Specimens that are manifestly faulty, or that give strengths differing by more than 15 per cent from the average value of all test specimens made from the same sample and tested at the same period, shall not be considered in determining the compressive strength.

Standard Specifications for

QUICKLIME AND HYDRATED LIME FOR COOKING OF RAGS IN PAPER MANUFACTURE[1]

A.S.T.M. Designation: C 45 - 25

ADOPTED, 1925.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 45; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover quicklime and hydrated lime suitable for use in the cooking of rags for the manufacture of paper.

NOTE.—Rags are cooked for the manufacture of paper in a digester under steam pressure with lime or with lime and soda ash. They are then washed to eliminate as much of the noncellulose material as possible.

General Requirements

2. (*a*) Either quicklime or hydrated lime may be furnished, as specified.

(*b*) The lime shall be clean and free from gritty substances.

Chemical Composition

3. The standard composition for quicklime and hydrated lime (percentages of available lime, calculated on the basis of the weight of sample taken at the place of manufacture) shall be as follows (Note):

	Quicklime	Hydrated Lime
Available lime, per cent...	90	64.3[a]

[a] Available lime of 64.3 per cent is equivalent to 85 per cent of available calcium hydroxide.

NOTE.—A standard composition without rejection limits is specified for the reason that lime of either higher or lower total oxides, available lime, calcium oxide, or calcium hydroxide than the standard may safely be used under suitable conditions for the purpose herein specified, depending primarily upon purely economic considerations. In the present state of the art, it is believed that the more serviceable type of specification for the product herein specified is that which defines a reasonable standard rather than one that fixes actual rejection limits. It is generally recognized that, other things being equal, lime meeting this standard is preferable to lime not meeting it, and lime surpassing the standard should be considered at a premium.

Methods of Testing

4. The chemical analysis for available lime shall be made in accordance with the Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation:

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1925, being revised in 1924 and 1925. Editorially revised and rearranged in 1939.

C 25) of the American Society for Testing Materials.[3]

Sampling, Inspection, etc.

5. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

QUICKLIME FOR SULFITE PULP MANUFACTURE[1]

A.S.T.M. Designation: C 46 – 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 46; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover quicklime suitable for use in the manufacture of sulfite pulp.

NOTE.—Lime is used in the "Milk of Lime" or "Tank System" of sulfite pulp manufacture for making the cooking liquor. The milk of lime is held in solution or suspension in a series of tanks equipped with suitable agitators. The sulfur dioxide is forced or drawn through these tanks successively. In some cases, the tanks are built on top of each other in the form of a tower. The contents of the first tank are drawn off when the liquor has reached a certain strength (3.5 to 6 per cent total SO_2) and the contents of the second and third tanks progress to the first and second tanks respectively. The third tank is again charged with fresh milk of lime. There are other systems of absorption which provide for continuous instead of intermittent operation. The function of the lime is to furnish the base for the formation of the bisulfites of calcium and magnesium.

General Requirements

2. Either calcium or magnesium lime may be furnished, but owing to the greater solubility and reactivity of magnesium bisulfite, high-magnesium lime gives the best results. The ratio of MgO to CaO shall be reasonably constant, and the lime shall be moderately free from impurities.

Chemical Composition

3. The quicklime shall conform to the following requirements as to chemical composition, all percentages to be calculated on the basis of the weight of the sample taken at the place of manufacture:[a]

	Calcium Lime	Magnesium Lime
Calcium oxide, min., per cent	92.5	55.4
Magnesium oxide, per cent	2.5 max.	39.6 min.
Oxides of silicon, iron and aluminum, max., per cent	3.0	3.0

[a] If it is desired to use the nonvolatile basis the figures given above should be changed to the following:

	Calcium Lime	Magnesium Lime
Calcium oxide, min., per cent	94.3	56.5
Magnesium oxide, per cent	2.6 max.	40.4 min.
Oxides of silicon, iron and aluminum, max., per cent	3.1	3.1

Methods of Testing

4. The chemical analysis of the lime shall be made in accordance with the

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1927, being revised in 1924, 1925, and 1927. Editorially revised and rearranged in 1939.

Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[3]

Sampling, Inspection, etc.

5. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

HYDRATED LIME FOR VARNISH MANUFACTURE[1]

A.S.T.M. Designation: C 47 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 47; the final number indicates the year of original adoption as standard or, in the case of revision the year of last revision.

Scope

1. These specifications cover hydrated lime suitable for use in the manufacture of oleoresinous varnishes.

NOTE.—Hydrated lime is used in the manufacture of oleoresinous varnishes to harden and partially neutralize the rosin. About 8 lb. of hydrated lime are gradually added to 100 lb. of the melted rosin and heated for a short period.

General Requirements

2. (*a*) The hydrated lime shall be of such a color that no pronounced darkening of the finished varnish will result. It shall be of such a texture and of such a fineness that all portions of it will rapidly come into intimate contact with the resins so as to enter into the chemical reactions with rapidity.

(*b*) The lime shall be completely hydrated (Note), since a high degree of hydration is important.

NOTE.—A very high calcium lime is preferred. It is especially important that the iron content be low in order to avoid undesirable color effects.

Chemical Composition

3. The hydrated lime shall conform to the following requirements as to chemical composition, calculated to the non-volatile basis:

Calcium oxide (CaO), min., per cent	94.0
Magnesium oxide (MgO), max., per cent	3.0
Iron oxide, aluminum oxide, and insoluble matter, max., per cent	3.0
Iron oxide (Fe_2O_3), max., per cent	0.4
Carbon dioxide (CO_2), max., per cent:	
If sample is taken at place of manufacture	3.0
If sample is taken at other than place of manufacture	5.0

Fineness

4. Not more than 10 per cent of the hydrated lime shall be retained on a No. 230 (62-micron) sieve.

Reactivity

5. The hydrated lime shall conform to the requirements of the tung-oil heat test as indicated in Section 6 (*c*).

Methods of Testing

6. (*a*) *Chemical Analysis.*—The chemical analysis of the lime shall be made in accordance with the Standard Meth-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1927. Editorially revised and rearranged in 1939.

ods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[3]

(*b*) *Fineness.*—One hundred grams of the sample as received shall be placed on a No. 230 (62-micron) sieve.[4] The material shall be washed by means of a stream of water from a faucet (Note). Washing shall be continued until the water coming through the sieve is clear. The residue upon the No. 230 (62-micron) sieve shall be dried to constant weight in an atmosphere free from CO_2 in a drying oven whose temperature is maintained between 100 and 120 C. (212 and 248 F.). The weight of this residue shall be calculated as a percentage of the original sample.

NOTE.—A small piece of rubber tubing attached to a water faucet will be found convenient. The velocity of the stream of water may be increased by pinching the tube, but the velocity should not be sufficient to cause any danger of splashing the sample over the sides of the sieve.

(*c*) *Tung-Oil Heat Test.*—A 1-g. sample of hydrated lime shall be stirred into 50 g. of raw tung oil[5] in a 100-ml. beaker. The resulting cloudy mass shall be heated. High-quality hydrated lime will usually start to react at approximately 80 C. (176 F.), small bubbles rising to the surface. As heating is continued, large flakes of lime tungate will form and rise to the surface to form a thick white scum, and the oil below will gradually become fairly clear. These changes will usually be completed when a temperature of 120 C. (248 F.) is reached. The heating shall be continued until the mass reaches a temperature of 140 C. (284 F.). It shall then be allowed to cool and the formation noted of the thick scum on the surface which will, when freed of air, gradually drop to the bottom of the beaker. This scum consists of tung oil soaps of lime which are quite insoluble in the oil. Addition of rosin will readily effect solution of these soaps.

A poor grade of lime will fail to react, the absence of bubbles or flakes of lime tungate being noticeable. The oil will remain quiescent and cloudy. Only small amounts of soaps will form on the surface.

Sampling, Inspection, etc.

7. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] Detailed specifications for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[5] Tung oil for this test should conform to the Standard Specifications for Raw Tung Oil (A.S.T.M. Designation: D 12), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

QUICKLIME AND HYDRATED LIME FOR USE IN THE TEXTILE INDUSTRY[1]

A.S.T.M. Designation: C 48 - 24

ADOPTED, 1924.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 48; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover quicklime and hydrated lime suitable for use in the textile industry in the treatment of the vegetable fibers (cotton, linen, and jute).

NOTE 1.—Lime is used in the textile industry for the following operations:

(*a*) Liming the kiers,
(*b*) Boiling out or scouring,
(*c*) Bleaching,
(*d*) Mercerizing,[3] and
(*e*) Water Softening.

These specifications apply only to the first three operations in connection with the treatment of the vegetable fibers: cotton, linen and jute. Lime for water softening is covered by the Standard Specifications for Quicklime and Hydrated Lime for Water Treatment (A.S.T.M. Designation: C 53) of the American Society for Testing Materials.[4]

NOTE 2.—Kier liming consists of applying a coating of whitewash to the inside of the kier and heating with steam. These two operations are repeated until a coating of the desired thickness is obtained. The lime serves to prevent the fibers from being stained by the iron kier.

NOTE 3.—The boiling-out process consists of soaking the fibers in a milk of lime, passing them through rollers into a kier, covering the fibers with water and boiling with steam either at atmospheric or higher pressures. The fibers then pass through a series of washings and treatments with acid and soda ash. The function of the lime is to saponify, hydrolyze, and neutralize whereby it makes possible, in following operations, the removal of fatty and greasy matters and pectin bodies. The fibers then consist of practically pure cellulose, the impurities being coloring matter not decomposed by alkalies.

NOTE 4.—Lime is used in the bleaching operation for making the "chemic" solution or hypochlorite bath. This bath may be made from bleaching powder or from lime and liquid chlorine. These specifications are limited to the process involving the use of lime and liquid chlorine. The operation consists of making a milk of lime and introducing chlorine under carefully controlled conditions until the mixture is nearly neutral. The sludge is allowed to settle and the clear hypochlorite solution is drawn off. After bleaching, the fibers are scoured and washed, and then passed on to the soda ash boil. Lime serves as a carrier of chlorine under conditions whereby the liberation of nascent oxygen and the resulting oxidation can be controlled in accordance with the special requirements of textile fibers. Bleach-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1924. Editorially revised and rearranged in 1939.

[3] Work is in progress on separate specifications for causticization (which is involved in mercerization).

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

ing decolorizes the fibers by oxidation of the coloring matter. It probably performs several other functions also, about which there is no general agreement.

General Requirements

2. Either quicklime or hydrated lime of fairly high calcium content may be furnished, as specified (Note).

NOTE.—There is a tendency to prefer quicklime for the boiling out and kier liming process, and hydrated lime for the mordanting process. Quicklime or hydrated lime which contains iron in a readily soluble form should be avoided as should also hydrated lime which contains a considerable amount of unhydrated magnesia.

Chemical Composition

3. The quicklime and hydrated lime shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

Calcium oxide (CaO), min., per cent	94.0
Magnesium oxide (MgO), max., per cent	3.0
Iron and aluminum oxides (Fe_2O_3 and Al_2O_3), max., per cent	2.0
Silica (SiO_2) and insoluble matter, max., per cent	2.5
Carbon dioxide (CO_2), max., per cent:	
If sample is taken at place of manufacture:	
Quicklime	3.0
Hydrated lime	5.0
If sample is taken at other than place of manufacture:	
Quicklime	5.0
Hydrated lime	7.0

Methods of Testing

4. The chemical analysis of the lime shall be made in accordance with the Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[4]

Sampling, Inspection, etc.

5. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[4]

Standard Specifications for

QUICKLIME AND HYDRATED LIME FOR SILICA BRICK MANUFACTURE[1]

A.S.T.M. Designation: C 49 - 42

ADOPTED, 1924; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 49; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover quicklime and hydrated lime suitable for use in the manufacture of silica brick (Note).

NOTE.—In the manufacture of silica brick, silica in the form of massive quartzite or quartz conglomerate is ground until the particles are less than ½ in. in size. Lime in the form of either slaked lime or hydrated lime is then added in quantities varying from 1.5 to 3.0 per cent CaO and the shapes are molded and dried. They are then burned in down-draft or tunnel kilns until most of the quartzite has been converted into tridymite or cristobalite.

General Requirements

2. Either quicklime or hydrated lime may be used. The lime shall be substantially free from ash, dirt, and core. Fineness of hydrate and rapidity of slaking of quicklime are desirable qualities.

Chemical Composition

3. The quicklime or hydrated lime shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

Calcium oxide (CaO), min., per cent	90.0
Magnesium oxide (MgO), max., per cent	4.5
Combined iron and aluminum oxides (Fe_2O_3 and Al_2O_3), max., per cent	1.5
Silica (SiO_2) and insoluble matter, max., per cent	3.0
Carbon dioxide (CO_2), max., per cent:	
If sample is taken at place of manufacture	5.0
If sample is taken at other than place of manufacture	10.0

Methods of Testing

4. The chemical analysis of the lime shall be made in accordance with the Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[3]

Sampling, Inspection, etc.

5. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1924.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

QUICKLIME AND HYDRATED LIME FOR WATER TREATMENT[1]

A.S.T.M. Designation: C 53 – 39

ADOPTED, 1927; REVISED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 53; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover lime suitable for use in the purification and softening of water for municipal and industrial supplies.

NOTE.—In the treatment of water for municipal and industrial supplies, lime is used alone or with iron sulfate or aluminum sulfate to produce a precipitate which assists in the clarification of the water and in the removal of the bacteria by filtration. An excess of lime is sometimes used to remove part of the hardness of the water. Lime and soda ash are used together for softening water. The lime serves as a chemical reagent in water treatment. The only useful constituent of the lime is the calcium oxide content of the quicklime or hydrated lime capable of reacting with the other chemicals in the water or added to it. Inert material, besides reducing the value in proportion to its amount, also makes more sludge to be disposed of for a given amount of chemical action and thus reduces the capacity of the equipment in which it is used.

General Requirements

2. (*a*) Either quicklime or hydrated lime may be furnished, as specified.

(*b*) Quicklime shall be substantially free of core, ash, and dirt, and shall be capable of disintegrating in water into a suspension of finely divided material.

Chemical Composition

3. The standard composition for quicklime and hydrated lime (percentages of available lime, calculated on the basis of the weight of sample taken at the place of manufacture) shall be as follows (Note):

	Quicklime	Hydrated Lime
Available lime, per cent . .	90	68.1[a]

[a] Available lime of 68.1 per cent is equivalent to 90 per cent of calcium hydroxide.

NOTE.—A standard composition without rejection limits is specified for the reason that lime of either higher or lower total oxides, available lime, calcium oxide, or calcium hydroxide than the standard may safely be used under suitable conditions for the purpose herein specified, depending primarily upon purely economic considerations. In the present state of the art, it is believed that the more serviceable type of specification for the product herein specified is that which defines a reasonable standard rather than one that fixes actual rejection limits. It is generally recognized that, other things being equal, lime meeting this standard is preferable to lime not meeting it, and lime surpassing the standard should be considered at a premium.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these specifications were published as tentative from 1924 to 1927, being revised in 1925 and 1927.

These specifications comprise a revision and consolidation of the former Standard Specifications for Quicklime for Use in Water Treatment (C 53 – 27) and for Hydrated Lime for Use in Water Treatment (C 54 – 27).

Methods of Test

4. The chemical analysis for available lime shall be made in accordance with the Standard Methods of Chemical Analysis of Limestone, Quicklime, and Hydrated Lime (A.S.T.M. Designation: C 25) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Sampling, Inspection, etc.

5. The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials.[3]

Standard Specifications for

SAND FOR USE IN PLASTER[1]

A.S.T.M. Designation: C 35 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 35; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Quality of Sand.—It is recognized that for certain purposes satisfactory results may be obtained with sands not conforming to these specifications. In such cases the use of sand not conforming to these specifications may be authorized only under special provisions based upon laboratory studies of the possibility of designing a mixture of materials to be used on the job that will yield plaster equivalent in quality to the specified mixture made with sand complying with these specifications in all respects.

Definition

1. Sand[3] for use in plaster shall consist of fine granular material composed of hard, strong, durable, uncoated particles which are free from injurious amounts of saline, alkaline, organic, or other deleterious substances.

Grading (Sieve Analysis)

2. (*a*) Sand for use in plaster shall be uniformly graded from fine to coarse within the following limits:

Retained on Sieve	Percentage Retained Max.	Min.
No. 4 (4760-micron)	0	..
No. 8 (2380-micron)	10	0
No. 30 (590-micron)	80	15
No. 50 (297-micron)	95	70
No. 100 (149-micron)	..	95

(*b*) The amount of material finer than a No. 200 (74-micron) sieve, shall not exceed 5 per cent.

(*c*) The sieves shall conform to the requirements of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[4]

Organic Impurities

3. The sand when subjected to the colorimetric test for organic impurities shall show a color not darker than the standard color, unless it is shown by adequate tests that the impurities causing the color are not harmful in plaster.

[1] Under the standardization procedure of the Society, these specifications are under the joint jurisdiction of the A.S.T.M. Committee C-7 on Lime and Committee C-11 on Gypsum.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1921 to 1925, being revised in 1924 and 1925. They were adopted in 1925, revised in 1930, but withdrawn and republished as tentative in 1936.

These specifications are in effect a revision and consolidation of, and replace the former Standard Specifications for Sand for Use in Gypsum Plaster (A.S.T.M. Designation: C 35) and the Tentative Specifications for Sand for Use in Lime Plaster (A.S.T.M. Designation: C 66 – 31 T), which specifications were accordingly discontinued in 1936.

[3] The term sand is defined in the Standard Definition of the Term Sand (A.S.T.M. Designation: C 58), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Methods of Testing

4. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Sieve Analysis.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[4]

(*b*) *Material Finer than No. 200 Sieve.*—Standard Method of Test for Amount of Material Finer than No. 200 Sieve in Aggregates (A.S.T.M. Designation: C 117).[4]

(*c*) *Organic Impurities.*—Standard Method of Test for Organic Impurities in Sands for Concrete (A.S.T.M. Designation: C 40).[4]

Standard Methods of

SAMPLING, INSPECTION, PACKING, AND MARKING OF QUICKLIME AND LIME PRODUCTS[1]

A.S.T.M. Designation: C 50 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 50; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods outline procedures for the sampling, inspection, rejection, retesting, packing, and marking of quicklime and lime products and are intended for use in connection with the individual specifications for lime.

SAMPLING

General

2. (*a*) Samples of quicklime and lime products shall be taken at the place of manufacture or at the destination, as may be agreed upon by the seller and the purchaser. If the samples are taken elsewhere than at the place of manufacture of the material, such samples shall be taken within 24 hr. of the receipt of the material.

(*b*) Samples may be taken from conveyors delivering to bins or piles, from filled bins by means of sampling tubes, from filled bins at the point of discharge, from piles by means of sampling tubes or shovels, or from loaded cars.

(*c*) Sampling shall be conducted as expeditiously as possible in order to avoid undue exposure of the material to the air. Samples shall not be taken from broken packages.

(*d*) Samples shall be taken in triplicate and immediately sealed in airtight, moistureproof containers. Samples shall be of an equal weight of not less than 5 lb. each when the quantity sampled equals 30 tons or more. For smaller quantities, the weights of the samples may be reduced proportionately, provided that no sample shall weigh less than 2 lb., except by agreement between the manufacturer and the purchaser.

(*e*) One sample shall be immediately delivered to the consignee; one sample shall be delivered to the consignor, if requested, within ten days from the date of sampling; the third sample shall be retained with the seal unbroken until such time as the material has been accepted or a referee test called for.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these methods were published as tentative from 1922 to 1927, being revised in 1923, 1924, and 1927. Editorially revised and rearranged in 1939.

Lump or Granular Material in Bulk

3. (*a*) *Piles or Cars.*—Material shall be selected so that it will represent an average of all parts of the pile or car and shall not contain a disproportionate share of the top or bottom layers. This material shall comprise at least ten shovelfuls taken from different parts of the pile or car. The total quantity so taken shall weigh not less than 100 lb. for a unit of 30 tons of material, with a proportionate quantity for multiples of this unit, provided that at no time shall the total amount of material so taken weigh less than 50 lb. It shall be broken, if necessary, to pass a 1-in. ring, thoroughly mixed and quartered, and the triplicate samples for testing shall be taken.

(*b*) *At Conveyors to or from Bins, Piles, or Cars.*—Material shall be taken at regular intervals during the entire time of movement of the mass being sampled. The quantity to be taken at each interval and the number of such intervals shall be so proportioned that the final quantity of material taken shall conform to the requirements prescribed in Paragraph (*a*).

Lump or Granular Material in Packages

4. At least 2 per cent of the packages shall be sampled, but in no case shall less than five packages be sampled. Individual packages shall be taken from various parts of the unit being sampled. The contents of each of the packages so taken shall be put in a pile, broken, if necessary, to pass a 1-in. ring, thoroughly mixed and quartered, and the triplicate samples for testing shall be taken.

Powdered Material in Bulk

5. (*a*) *Bins, Piles, or Cars.*—A sampling tube shall be used which takes a core not less than 1 in. in diameter, and which is of sufficient length to permit the taking of a core from the top to the bottom of the mass being sampled. Cores shall be taken from at least ten separate parts of the mass. The cores so taken shall be thoroughly mixed and quartered, and the triplicate samples for testing shall be taken from the material so selected and prepared. A minimum quantity of 100 lb. shall be taken for a unit of 30 tons of material, with a proportionate quantity for multiples of this unit, provided that at no time shall less than 50 lb. be taken as the original portion.

(*b*) *At Conveyors to or from Bins, Piles, or Cars, at Packing Machines, etc.*—Sampling at conveyors, packing machines, etc., shall conform to the provisions of Section 3 (*b*).

Powdered Material in Packages

6. At least 1.5 per cent of the packages shall be sampled, but in no case shall less than five packages be sampled. Individual packages shall be taken from various parts of the unit being sampled. A sampling tube shall be used which takes a core not less than $\frac{1}{2}$ in. in diameter. The tube shall be inserted into the package being sampled so that it will take a core of the material from substantially the entire length of the package. Material thus taken from individual packages shall be thoroughly mixed and quartered, and the triplicate samples for testing shall be taken from the material so selected and prepared.

Treatment of Sample at Laboratory

7. (*a*) *Sample for Chemical Analysis.*—The sample as received at the laboratory shall be thoroughly mixed, and reduced in quantity by the usual methods of quartering to give a minimum portion of 75 g. This portion shall be ground, either by a suitable mechanical device or by hand in an agate mortar, until it all passes a No. 100 (149-micron)

sieve.[3] This 75-g. sample shall then be thoroughly mixed and placed in an airtight container for use in the chemical analysis.

(*b*) *Samples for Special Tests.*—Samples to be used for such special tests as may be required by individual specifications shall be obtained by mixing and quartering the material remaining after removal of the 75-g. portion for chemical analysis. The quantity of sample and the sieve size of the particles will depend upon the requirements of the individual specifications.

INSPECTION

Inspection

8. When inspection and sampling are to be conducted at the place of manufacture, the manufacturer shall afford the inspector representing the purchaser all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the operation of the works. The duties of the inspector or sampler shall be confined exclusively to sampling and inspection of the finished material as ready for shipment, and shall not under any circumstances be construed to permit investigation of methods or processes of manufacture.

REJECTION

Rejection

9. (*a*) Rejection of material based on failure to pass the tests prescribed in the specifications shall be reported to the manufacturer within ten days from the taking of samples, and the cause for rejection shall be stated.

(*b*) The samples which represent rejected material shall be kept in airtight, moistureproof containers for at least five days from the date of the original test report.

RETESTING

Retesting

10. (*a*) Either of the contracting parties may make claim for a retest within five days of the date of the original test report. The expense of the retest shall be borne by the party demanding such retest.

(*b*) Should the contracting parties be unable to reach a mutually satisfactory agreement based upon the results of the original test, the third sample of the material shall be delivered unopened to a referee laboratory for test and the results of this referee test shall be binding on both parties.

PACKING

Packing

11. (*a*) *Lump Lime.*—Lump lime may be shipped in bulk in carload lots, in wooden barrels or steel containers holding 180 lb. or 280 lb. net each, or in pasteboard cartons holding 90 lb. net each.

(*b*) *Pulverized Lime.*—Pulverized lime may be shipped in bulk, in carload lots, or in cloth or paper bags.

(*c*) *Hydrated Lime.*—Hydrated lime shall be shipped in cloth bags holding 100 lb. net each, or in paper bags holding 50 lb. net each.

MARKING

Marking

12. (*a*) Each shipment of material shall carry with it some means of identification, stating the particular contract on which the purchase and shipment were made.

(*b*) Each package shall have legibly marked thereon, the net weight of its contents, the name of the manufacturer, the place of manufacture, and the brand

[3] Detailed requirements for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

name, if any. This marking shall comply with all requirements of the Federal Lime Barrel Act, entitled "An Act to Standardize Lime Barrels (Public No. 228 - Congress - S 5425)," and with such other federal or state laws as may be applicable to the shipment in question.

(*c*) In addition to the above information, the following guarantee may be marked on each package or shipment: "Guaranteed by (name of manufacturer) to meet the specifications of the American Society for Testing Materials" for (name of material).

Standard Methods of

CHEMICAL ANALYSIS OF LIMESTONE, QUICKLIME, AND HYDRATED LIME[1]

A.S.T.M. Designation: C 25 - 44

ADOPTED, 1929; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 25; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover procedures for the chemical analysis of limestone, quicklime, and hydrated lime.

NOTE.—"The Analysis of Silicate and Carbonate Rocks," U. S. Geological Survey *Bulletin 700*, should be used for reference in connection with these methods, especially when very exact and detailed analyses are desired. Blank determinations should be made on all reagents, and corrections applied when necessary.

Samples for Analysis

2. Samples for chemical analysis shall be taken and prepared in accordance with the requirements of the Standard Methods of Sampling, Inspection, Packing, and Marking of Quicklime and Lime Products (A.S.T.M. Designation: C 50) of the American Society for Testing Materials[3] applicable to the material to be tested.

Special Solution Required

3. *Standard Potassium Permanganate Solution.*—Dissolve 5.64 g. of $KMnO_4$ in 1000 ml. of water. Let age for one week or more. Filter through purified asbestos and standardize against the National Bureau of Standards' standard sample 40c of sodium oxalate as follows: Transfer 0.5 g. of the standard sodium oxalate, dried at 105 C., to a 400-ml. beaker. Add 250 ml. of diluted H_2SO_4 (5:95), freshly boiled for 10 to 15 min. and cooled to 27 ± 3 C. Stir until the oxalate has dissolved. Add 40 to 42 ml. of the standard $KMnO_4$ at the rate of 25 to 35 ml. per min., while stirring slowly. Let stand until the pink color disappears (about 60 sec.). (If the pink color should persist because of the addition of an excess of $KMnO_4$ solution, discard and begin again, adding a few milliliters less of the $KMnO_4$.) Heat to 55 to 60 C. and complete the titration at this temperature by adding $KMnO_4$ until a faint pink color persists for 30 sec. Add the last 0.5 to 1 ml. drop by drop, with particular care to allow each drop to become decolorized

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these methods were published as tentative from 1919 to 1929, being revised in 1921, 1922, 1925, 1926, and 1927.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

before the next is introduced. Determine the excess of $KMnO_4$ required to impart a pink color to the solution by matching the color in another beaker containing the same amount of the specially treated diluted H_2SO_4 at 55 to 60 C. One milliliter of the standard $KMnO_4$ will be approximately equivalent to 0.005 g. of CaO.[4] The exact value shall be calculated from the following equations:

$$5\ Na_2C_2O_4 + 2\ KMnO_4 + 8\ H_2SO_4 = 5\ Na_2SO_4 + K_2SO_4 + 2\ MnSO_4 + 10\ CO_2 + 8\ H_2O$$

$$5\ CaC_2O_4 + 2\ KMnO_4 + 8\ H_2SO_4 = 5\ CaSO_4 + K_2SO_4 + 2\ MnSO_4 + 10\ CO_2 + 8\ H_2O$$

Insoluble Matter Including Silicon Dioxide

4. Weigh out approximately 0.5 g. of the sample[5] and, if a limestone or hydrated lime, ignite in a covered platinum crucible in an electric muffle[6] for 15 min., or longer if the heat is not powerful enough to effect complete decomposition within that time. Transfer to an evaporating dish, preferably of platinum[7] for the sake of celerity in evaporation, mix to a thin slurry with distilled water, add 5 to 10 ml. of HCl (sp. gr. 1.18), and digest with aid of gentle heat and agitation until solution is complete. Solution may be aided and the time shortened by light pressure with the flattened end of a glass rod upon resistant lumps. Then evaporate the solution to dryness, so far as this may be possible, on the water bath. When dry or nearly so, place the dish and its contents (covered) in an air bath or on a platinum triangle resting on a hot plate and, if a limestone of high calcium content is under treatment, heat for 1 hr. at 200 C.; if a limestone of high magnesium content is under treatment the temperature should not exceed 120 C. Drench the cooled mass with HCl (sp. gr. 1.18) and allow to stand for a few minutes. Add an equal volume of water, cover the dish, and place on the water bath for 10 min.[8] Separate the SiO_2 by filtration on a filter of suitable size. Wash thoroughly with diluted HCl and then wash twice with cold water. Evaporate the filtrate to dryness. Extract the residue with HCl as before but allowing only a few minutes time. Filter this solution through a second and smaller paper. Transfer the wet papers containing the separated residue to a weighed platinum crucible. Char carefully without allowing the paper to inflame, and then ignite to constant weight in an electric muffle.[6] The increase in weight represents the insoluble and siliceous matter and is reported as insoluble matter, including silicon dioxide.

Silicon Dioxide

5. (*a*) Treat the "insoluble matter including silicon dioxide," (Section 4) in the crucible with 5 ml. of water, 5 ml. of HF and one or two drops of H_2SO_4,[9] and evaporate to dryness. Heat the residue for 2 or 3 min. in an electric muffle[6] and again weigh. The difference between this weight and that previously obtained gives the weight of SiO_2.[10]

[4] With high calcium limes, more than 50 ml. of this solution probably will be required to titrate the liberated oxalic acid. In such cases the use of a larger burette is to be preferred to increasing the strength of the permanganate solution.

[5] Due to the rapidity with which quicklime and hydrated limes become contaminated by absorption of water and carbon dioxide from the air, samples must be protected in tightly stoppered containers at all times. Samples for analysis are to be weighed from stoppered weighing bottles, the exact weight of the samples being determined by the difference in weight of the bottles before and after the samples are removed.

[6] Ignition of the sample in an electric muffle is far superior to flame ignition. If an electric muffle is not available, flame ignition and the blast lamp may be used.

[7] If a platinum dish is not available, porcelain may be used. A glass container positively must *not* be used.

[8] Instead of strong acid, that of half strength may be used and the heating begun at once.

[9] See U. S. Geological Survey *Bulletin 700*, p. 103.

[10] For ordinary control work in the plant laboratory this correction may, perhaps, be neglected; the double evaporation must never be neglected.

(*b*) To determine SiO_2 by volatilization with HF, fuse the residue in the crucible with a little Na_2CO_3,[11] cool the melt and dissolve it in diluted HCl. Add the solution to the filtrate from the second evaporation for "insoluble matter including silicon dioxide" (Section 4). If the "insoluble matter including silicon dioxide," is reported as such and no HF treatment is given, the "insoluble matter including silicon dioxide," is not fused or further treated.

Insoluble Matter other than Silicon Dioxide

6. The difference between the weight of "insoluble matter including silicon dioxide" and silicon dioxide represents the "insoluble matter other than silicon dioxide."

Iron and Aluminum Oxides

7. To the HCl solution from the determination of SiO_2 add a few drops of bromine water or HNO_3 and boil the solution until all trace of bromine or chlorine is gone. Then add HCl, if not already present, sufficient to ensure a total volume of 10 to 15 ml. of HCl (sp. gr. 1.18).[12] Add a few drops of methyl red solution and after diluting to 200 to 250 ml. heat the liquid to boiling. Neutralize by means of NH_4OH (diluted towards the end) until the color of the liquid changes to a distinct yellow. Boil for 1 or 2 min., allow to settle, filter, and immediately wash the precipitate two or three times with hot NH_4Cl (2 per cent) and dry by suction.[13] Set the filtrate aside. Dissolve any precipitate from the paper in hot, diluted HCl, the solution passing into the beaker in which the precipitation was made, and wash the paper thoroughly with hot water. Boil the solution to expel any trace of chlorine, and precipitate the hydroxides with NH_4OH as before. Ignite the moist precipitate in a weighed platinum crucible,[7] cool, and weigh as Al_2O_3 and Fe_2O_3.[14]

Total Iron, Standard Procedure

8. Fuse the combined iron and aluminum oxides[15] (Section 7) in a platinum crucible at a very low temperature with 3 to 4 g. of $Na_2S_2O_7$ or $K_2S_2O_7$.[16] Treat the melt with sufficient diluted H_2SO_4 to insure the presence of not less than 5 g. of absolute acid and enough water to effect solution on heating. Evaporate the solution and eventually heat until acid fumes come off copiously. After cooling and redissolving in water, filter out the small amount of SiO_2, wash, ignite, weigh, and correct by HF and H_2SO_4.[17] Add the weight so corrected to the weight of SiO_2 previously found and deduct from the gross weight of the oxides of iron and aluminum. Reduce the filtrate by zinc.[18] Titrate with a 0.05 *N* $KMnO_4$ solution.

Total Iron, Alternative Procedure

9. (*a*) Dissolve 2 to 5 g. (depending upon the amount of iron present) of the properly prepared sample in HCl and evaporate rapidly to dryness. Treat the residue with water and HCl, filter off the SiO_2, and wash several times with hot water. Precipitate the iron in a

[11] Fusion with pyrosulfate is to be avoided on account of the subsequent introduction of sulfates into the solution.

[12] See U. S Geological Survey *Bulletin 700*, p. 258.

[13] See U. S. Geological Survey *Bulletin 700*, p. 107.

[14] This precipitate may also contain TiO_2, P_2O_5, and Mn_3O_4.

[15] When the iron is present in small quantities it is rather unsatisfactory to determine it in the ignited oxides from the 0.5-g. sample. Under these conditions the alternative procedure may be used.

[16] The pyrosulfates are less troublesome and more effective than the bisulfates.

[17] This correction for impurities should not be made when the HF correction of the main SiO_2 determination has been omitted. After two evaporations, 1 to 2 mg. of SiO_2 are still to be found with the R_2O_3 precipitate.

[18] Zinc will also reduce titanium. If this metal is to be determined and deducted from Al_2O_3, then H_2S must be used for reduction (boiling out the H_2S in a stream of CO_2 before titration). If titanium is not to be determined, the slight error introduced by its reduction with zinc is so small as to be negligible except in the most exact and detailed analyses.

boiling solution with fixed alkali, allow to settle, filter, and wash free of chlorides, using hot water. Dissolve in diluted H_2SO_4.

(*b*) Ignite the insoluble matter from the evaporated HCl solution in a platinum crucible. Treat with H_2SO_4 and HF and heat until fumes of H_2SO_4 appear. Bring the residue into solution with the addition of a few drops more of H_2SO_4 and combine the solution with that of the bulk of the iron. Reduce this solution by zinc and titrate the iron with 0.05 *N* $KMnO_4$.

Aluminum Oxide

10. Subtract the calculated weight of Fe_2O_3, obtained in accordance with Section 8, from the weight of $Al_2O_3 + Fe_2O_3$ (Section 7). Report the remainder as Al_2O_3. In case phosphorus is determined, calculate it to P_2O_5 and deduct also.

Calcium Oxide by Gravimetric Method[19]

11. Add a few drops of NH_4OH to the combined filtrate from the $Al_2O_3 + Fe_2O_3$ precipitate, and bring the solution to boiling. To the boiling solution add 35 ml. of a saturated solution of $(NH_4)_2C_2O_4$, and continue the boiling until the precipitated CaC_2O_4 assumes a granular form. Allow it to stand 20 min., or until the precipitate has settled and the supernatant liquid is clear, filter, and wash thoroughly with boiling water.[20] Place the wet filter and precipitate in a platinum crucible, and burn off the paper over the small flame of a bunsen burner or in a muffle. Ignite the residue, dissolve in hot diluted HCl, and make up the volume of the solution to 100 ml. with water. Add NH_4OH in slight excess and boil the liquid. If a small amount of $Al_2(OH)_6$ separates, filter it out, wash with NH_4Cl (2 per cent), ignite, weigh, and add this weight to that found in the first determination. Then reprecipitate the lime by $(NH_4)_2C_2O_4$, allow to stand until settled, filter, wash thoroughly with boiling water,[20] and weigh as CaO after ignition to constant weight in a covered platinum crucible.

Calcium Oxide by Volumetric Method[21]

12. Make the filtrate from the iron and aluminum oxide precipitate alkaline with NH_4OH, boil, and add 35 ml. of a boiling saturated solution of $(NH_4)_2C_2O_4$. Stir vigorously and allow to stand until the precipitate has settled, filter on an 11-cm. paper, and wash ten times with hot water.[22] Transfer the paper and precipitate to the beaker in which the precipitation was made, spreading the paper out against the upper portion of the beaker. Wash the precipitate from the paper with a jet of hot water, fold the paper, and leave it adhering to the upper portion of the beaker. Add to the contents of the beaker 50 ml. of diluted H_2SO_4 (1:10), dilute to a volume of 250 ml. with hot water, and heat to 80 to 90 C. Titrate with the standard $KMnO_4$ solution (Section 3) until the pink end point is obtained. Now drop the folded filter paper (which has been adhering to the side of the beaker) into the liquid; the pink color of the latter will be discharged. Finish the titration by adding $KMnO_4$ drop by drop until the pink end point is again obtained. A Gooch crucible may be used instead of filter paper. From the total quantity of standard $KMnO_4$ solution used, calculate the percentage of CaO.

---

[19] The gravimetric method must be employed when a recovery of aluminum is desired, or when a determination of strontium is contemplated.

[20] Care must be exercised in this washing, as 1000 ml. of boiling water will dissolve over 10 mg. of CaC_2O_4.

[21] The volumetric method may be used for ordinary control work in the plant laboratory. It must be borne in mind that in this method all strontium oxide is reported as calcium oxide.

[22] Use not more than 125 ml. for this wash.

Strontium Oxide

13. Transfer the weighed oxides obtained in the gravimetric determination of calcium oxide (Section 11) to a small flask of 20-ml. capacity and dissolve in HNO_3. Evaporate to dryness and heat at 150 to 160 C. Treat the thoroughly dried nitrates with as little (rarely over 2 ml.) of a mixture of equal parts of absolute alcohol and ether as may be needed to dissolve the calcium salt, solution being hastened by occasional gentle agitation. After standing over night in the corked flask, collect the insoluble matter on the smallest possible filter and wash with more of the above mixture of alcohol and ether. After drying, pass a few milliliters of hot water through the filter, on which may remain a few tenths of a milligram of residue which usually does not contain any lime or other alkaline earth and whose weight is therefore to be deducted from that of the lime unless it can be shown that it is derived from the glass of the small flask in which the nitrates of calcium and strontium were evaporated. To the solution of strontium nitrate in a small beaker add a few drops of H_2SO_4 and then its volume of alcohol, whereby the strontium is precipitated as sulfate. After 12 hr., filter on a small filter paper, and wash the residue with 50 per cent alcohol. Ignite at a low temperature, moisten with diluted H_2SO_4, evaporate, again ignite, and weigh as $SrSO_4$. Test the sulfate spectroscopically as to freedom from calcium and barium. Calculate the weight of SrO and deduct from the weight of CaO as obtained in Section 11.

Magnesium Oxide

14. (*a*) Acidify the combined filtrates from the calcium precipitates with HCl, concentrate on the water bath to about 150 ml., and heat to boiling. To the boiling solution add 10 ml. of a saturated solution of $Na(NH_4)HPO_4$ and continue the boiling for several minutes. Then cool to room temperature, and add NH_4OH drop by drop, while stirring constantly, until the crystalline ammonium-magnesium orthophosphate begins to form and then in moderate excess, the stirring being continued for several minutes. Allow the liquid to stand in a cool atmosphere for from 12 to 48 hr.[23] and filter.

(*b*) Dissolve the precipitate in hot diluted HCl, dilute the solution with water to about 100 ml., add 1 ml. of the saturated solution of $Na(NH_4)HPO_4$ and NH_4OH drop by drop, while stirring constantly, until the precipitate is again formed as above described and the NH_4OH is present in moderate excess. Then allow it to stand in a cool atmosphere for from 12 to 48 hr.[23] Filter on paper or in a Gooch crucible, wash with diluted NH_4OH containing NH_4NO_3,[24] ignite,[6] cool, and weigh as $Mg_2P_2O_7$.[25]

Loss on Ignition

15. Place 1 g. of the prepared sample[26] in a weighed platinum crucible, cover with the lid, and heat gently[6] for 5 min., gradually increasing the temperature to the maximum of the muffle, and maintain at this temperature until constant weight is obtained (usually about 15 min.). The difference between the original weight of the sample and the final weight represents the loss on ignition.

---

[23] The less the amount of magnesium present, the longer the precipitate must be allowed to settle.

[24] Made by diluting NH_4OH with distilled water until the solution contains 2.5 per cent of NH_3 by weight, then adding three or four drops of HNO_3 (sp. gr. 1.42).

[25] When manganese is present in the sample, it will be caught in large part with the magnesium precipitate. (See U. S. Geological Survey *Bulletin 700*, p. 134.) In case manganese was not eliminated before this precipitation, the weighed pyrophosphate must be dissolved in HNO_3, tested for manganese with bismuthate, the manganese determined and deducted as $Mn_2P_2O_7$.

[26] This determination may be made, if desired, upon the 0.5-g. sample ignited for solution in HCl as described in Section 4.

Mechanical Moisture in Limestone

16. Weigh 1 g. of the prepared sample in a tared, wide, low-form, flat-bottomed weighing bottle. Heat uncovered in a ventilated drying oven at 120 C. for 2 hr. Quickly stopper, cool in a desiccator, and weigh, lifting the stopper momentarily just before weighing. The use of a similar weighing bottle as a counterpoise carried through all of the operations is a desirable procedure. The loss in weight represents "mechanical moisture" or "hygroscopic water" at 120 C.

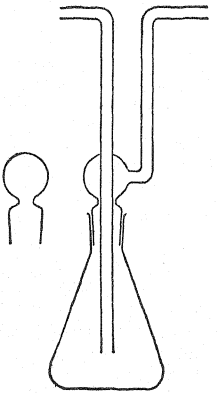

FIG. 1.—Bottle for Determination of Superficial Moisture.

Mechanical Moisture in Hydrated Lime

17. (*a*) *Arrangement of Apparatus.*—Mechanical moisture in hydrated limes shall be determined by aspirating over the sample in a closed container at 120 C. a slow stream of dry, CO_2-free air. The container for the sample shall be equipped with two interchangeable stoppers one to be used during weighings and the other to be used during the drying. The second stopper shall be equipped with two entry tubes for conducting the air stream over the sample.[27] (See Fig. 1.) The container shall be connected in a train, having before it a soda-lime tower, a lime-water bottle, a sulfuric acid bottle, and a phosphoric anhydride bulb, in the order named, and after it another protective phosphoric anhydride bulb. The lime-water bottle is useful for giving indication of the exhaustion of the soda lime. The train shall be placed in position, with connection for the sample bottle, in a drying oven at 120 C.

(*b*) *Procedure.*—Place 2.5 to 3 g. of the prepared sample into the previously weighed bottle, and immediately restopper it. A glazed paper funnel will aid rapid manipulation. Insert the bottle in the train by quickly exchanging the stoppers, and draw a slow current of dry, CO_2-free air through the apparatus for 2 hr. Remove the sample bottle from the oven with another quick exchange of stoppers, and set it in a desiccator to cool. When cool, remove it to the balance case for several minutes before weighing it, and just before weighing, lift the stopper slightly for an instant to relieve any vacuum that may exist in the bottle. The loss in weight of the sample represents "mechanical moisture" or "hygroscopic water" at 120 C. Use a bottle similar to the one containing the sample as a counterpoise in all weighings.

Carbon Dioxide by Standard Method[28]

18. (*a*) *Size of Sample.*—With limestone, use 0.5 g. of the sample; with

[27] A small bottle of 20 to 30-ml. capacity with glass stoppers, as described, ground to fit, is a convenient form of apparatus. (See Fig. 1.)

[28] This method is in accordance with the method given in U. S. Geological Survey *Bulletin 700*, p. 217. An illustration showing the arrangement of the component parts of the necessary apparatus is shown on p. 218 of that Bulletin.

burned lime, hydrated lime, etc., use 5 g. of the sample.

(*b*) *Procedure.*—Boil the weighed amount of prepared sample with diluted HCl(1:1) in a small Erlenmeyer flask attached to an upwardly inclined condenser, whence, after passing through a drying system—calcium chloride, anhydrous copper sulfate to retain hydrogen sulfide from decomposable sulfides and any HCl that may pass over, then calcium chloride again—the CO_2 is caught by absorption tubes filled with soda lime followed by calcium chloride. the observation bulbs (containing H_2SO_4 to show the rate of gas flow) being attached directly to the drying system. Then close the stopcock in the separatory funnel, half fill the latter with HCl (1:1), replace the rubber stopper of the funnel, insert the absorption tubes between the drying system and the observation bulbs, and allow the acid to flow into the flask, slowly if there is much CO_2, rapidly if there is but little. When effervescence diminishes in the former case, at once in the latter, light the burner under the flask and start the

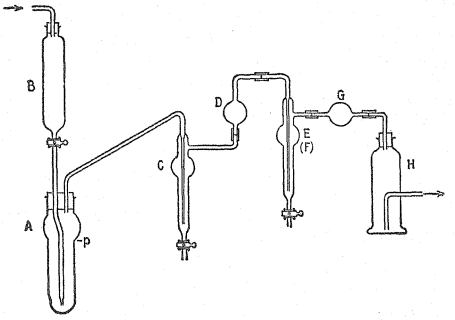

FIG. 2.—Apparatus for Determination of Carbon Residue.

Arrangements should be made for a current of air free from CO_2 with which to sweep out the apparatus before and after the determination, and for a slow current during its continuance. The results are very accurate and the determination can be quickly carried out. The manipulations are as follows: Pour hot water upon the powder in the flask fitted with a separatory funnel and delivery tube; attach this to the condenser, and force a current of air free from CO_2 through the whole system, except the weighed absorption tubes, until the original air has been displaced, flow of water through the condenser. Keep the flame low, so as to secure steady but quiet ebullition, and do not interrupt the air current although it should be reduced to a slow rate. With much CO_2 the rate of absorption is very readily noted by holding the hand to the soda-lime tubes, which become hot or warm when absorption is taking place. Sufficient time having elapsed,[29] extinguish the flame and increase the air current. When cool, disconnect the

[29] Boiling for 1 min. is usually sufficient.

soda-lime tubes from the apparatus and allow to stand in the balance case until two weights taken 30 min. apart agree within 0.5 mg. The soda lime for use in this determination must be porous, not hard and unabsorptive like that sometimes used for the combustion of nitrogenous organic substances.

Carbon Dioxide by Alternative Method

19. (*a*) *Apparatus.*—The apparatus illustrated in Fig. 2, which is a modification of the usual form, may be used if desired. The principle of its operation is the same as that of the procedure described in Section 18. The apparatus consists of the following:

Tube A, for decomposition of the sample.

Tube B, to contain acid. A soda-lime tower is placed ahead of tube *B* so that air drawn through the apparatus is free of CO_2.

Micro-drier C, containing water, to act as a condenser and to retain most of the acid volatilized from tube *A*.

Bulb D, containing mossy zinc to remove the last traces of HCl.

Micro-drier E, containing H_2SO_4 to dry gases. If the sample evolves H_2S, another micro-drier, *F*, containing cadmium chloride solution is inserted between bulb *D* and micro-drier *E*.

Bulb G, containing P_2O_5 to complete the drying of the gases.

Midvale Bulb H, for absorption of CO_2. It is filled as follows: A layer of glass wool extending above the end of the outlet tube is placed in the bottom, and on this a layer of P_2O_5, about $\frac{3}{4}$ in. thick. Immediately on this is placed another layer of glass wool, and the rest of the bulb is filled with ascarite, except for a final layer of glass wool on the top.

(*b*) *Size of Sample.*—With limestone, use 0.5 g. of the sample; with burned lime, hydrated lime, etc., use 3 to 5 g. of the sample.

(*c*) *Procedure.*—The manipulations are as follows: Sweep out tubes *C*, *D*, *E*, *F*, and *G* with a current of CO_2-free air. Place in tube *B* sufficient HCl (sp. gr. 1.1) to completely decompose the sample, but so regulated in volume that the liquid level in tube *A* shall not be above the point *P*. Connect a soda-lime tower to the top of tube *B*. Introduce rapidly into tube *A* the weighed amount[5] of the prepared sample, and immediately cover it with CO_2-free water and attach to the apparatus. Then attach the weighed Midvale bulb *H*. Allow the acid from tube *B* to flow into tube *A*, the rate being governed by the rate of evolution of gas. Then gently heat tube *A* and boil to expel all CO_2[29] while drawing a slow current of air free from CO_2 through the apparatus. Continue the air current for 3 min. after removing the flame. Disconnect the Midvale bulb *H* and weigh it after it has come to equilibrium in the balance case. Use a second Midvale bulb as counterpoise in all weighings.

Sulfur Trioxide

20. Place 2 g. of the prepared sample in a small, dry beaker and stir it up with 10 ml. of cold water until all lumps are broken and the lighter particles are in suspension. Add 15 ml. of diluted HCl (1:1) and heat until solution is complete. Filter through a small paper and wash the residue thoroughly with hot water. Dilute the filtrate to 250 ml., heat to boiling, and add 10 ml. of a boiling solution of $BaCl_2$ (10 per cent) drop by drop, while stirring constantly. Stir well and allow to stand over night. Filter, wash with boiling water, ignite, and weigh as $BaSO_4$.

Total Sulfur

21. Weigh 1 g. of the prepared sample. Add approximately 0.5 g. of Na_2CO_3.

Mix thoroughly in a porcelain crucible[30] and heat gently until sintered. Then ignite for 15 min. at a temperature of approximately 1000 C., taking care to allow access of air to the contents of the crucible. Cool and place the crucible in a 250-ml. beaker and cover with hot water. Add 10 ml. of bromine water, then 30 ml. HCl (1:1) and boil until solution is complete and all bromine has been expelled. Remove the crucible, washing it with water. Add a few drops of methyl red and render the solution alkaline with NH_4OH (1:1). Boil the solution for 1 or 2 min., filter, and wash with hot water. To the filtrate add 5 ml. of HCl (1:1), adjust the volume to about 200 ml., bring the solution to boiling, and while boiling add 10 ml. of hot $BaCl_2$ (10 per cent). Allow to stand overnight. Filter, wash with hot water, ignite, and weigh as $BaSO_4$.

Phosphorus

22. Dissolve 10 g. of the prepared sample in 80 ml. diluted HNO_3 (1:1), filter, and wash the residue with hot water. Ignite, fuse the residue with a little Na_2CO_3, cool the melt, and add its nitric acid solution to the main filtrate.[31] In case the rock is rather argillaceous, mix the powder with half its weight of Na_2CO_3 and blast strongly. Dissolve the cooled melt in HNO_3 and evaporate to dryness. Take up the dry residue with diluted HNO_3 (1:2), filter, and wash the residue with hot water. Ignite the residue in platinum, and evaporate with HF and HNO_3. Finally, evaporate twice with HNO_3 alone to expel all fluorine, dissolve the residue in HNO_3 and add the solution to the main filtrate.[31] Oxidize the nitric acid solution by boiling with 10 ml. of $KMnO_4$ (1.5 per cent) until MnO_2 is precipitated. Dissolve the oxide by addition of H_2SO_3 or a sulfite free from phosphorus and boil to expel the oxides of nitrogen and sulfur. Neutralize the HNO_3 with NH_4OH and then add 1 ml. of HNO_3 (sp. gr. 1.42) for every 100 ml. of solution. Bring the solution to a temperature of 40 C., add ammonium molybdate solution[32] and shake for 10 min. Allow to stand at a temperature of not over 40 C. for 1 to 12 hr. Filter and wash ten times with KNO_3 (1 per cent). Return the precipitate to the precipitating vessel, add a measured excess of 0.1 *N* NaOH and 25 ml. of water free from CO_2 and shake or stir until the precipitate is dissolved. Dilute to 100 to 200 ml. with water free from CO_2, add 3 drops of phenolphthalein (0.2 per cent), and discharge the pink color with standard acid. Finish the titration by adding standard alkali until the reappearance of the pink color. The alkali solution should be free from carbonate and be standardized against the National Bureau of Standards' standard sample 39*e* of benzoic acid.[33] The ratio of phosphorus to NaOH should be considered as 1:23 in calculating results.[34]

Manganese

23. Dissolve 10 g. of the sample in 100 ml. of diluted HNO_3 (1:1), filter, and

[30] It is usually desirable to make a fusion in a platinum crucible. However, it has been found that with limestones very high in impurities, when the fusion is made in a muffle, the damage to platinum ware is considerable. It has been proved that the use of porcelain crucibles introduces no appreciable error.

[31] In limestones very low in phosphorus it may be deemed desirable to concentrate the phosphorus from a considerable weight of sample. In this case, proceed as directed by F. Hinden (*Zeitschr. Anal. Chemie*, Vol. 54 p. 214 (1915)), as follows: To the nitric acid solution of the large sample add a few drops of $FeCl_3$ solution and then NH_4OH until the liquid becomes slightly turbid. Then add 0.5 g. of pure precipitated $CaCO_3$ and boil for 5 min. Filter, dissolve the precipitate in diluted HNO_3, and proceed as above.

[32] See Blair, "The Chemical Analysis of Iron," 8th Edition, p. 92.

[33] See *Journal*, Am. Chem. Soc., Vol. 34, p. 1027 (1912), and Vol. 35, p. 1309 (1913).

[34] Titanium and vanadium, which interfere in this determination, should not be encountered in appreciable amounts in this class of material.

Instead of the specified alkalimetric titration method, the phosphorus in the phosphomolybdate may be determined as magnesium pyrophosphate (U. S. Geological Survey *Bulletin 700*, pp. 178-179), or by the reductor method (A. A. Blair, "Chemical Analysis of Iron," 8th Edition, pp. 91-92).

wash the residue with hot water. Ignite the residue in platinum, fuse with a little Na_2CO_3, and add the nitric acid solution of the melt to the main filtrate. Dilute the solution to 150 ml. and add 0.5 g. of sodium bismuthate.[35] Heat for a few minutes, or until the pink color has disappeared and MnO_2 has precipitated. If MnO_2 does not precipitate add more bismuthate. Clear the solution by adding a few drops of a saturated solution of sodium bisulfite or other suitable reducing agent free from chlorides, and boil to expel all oxides of nitrogen and sulfur. Cool to 15 C., add an excess of sodium bismuthate, agitate, and let stand for a few minutes. Add 50 ml. of HNO_3 (3 per cent) and filter through asbestos. Wash with HNO_3 (3 per cent) until the washings run through colorless. Add a measured excess of a standard $FeSO_4$ solution and titrate back with a standard $KMnO_4$ solution, the strength of which has been determined by means of the National Bureau of Standards' standard sample 40c of sodium oxalate.[36]

Ferrous Iron in the Absence of Carbonaceous Matter[37]

24. Introduce the powder, one to several grams, into a stout flask of about 200 to 250-ml. capacity and boil with a little water until all air is expelled. While still boiling, add diluted H_2SO_4 a little at a time until effervescence ceases, then a further amount. Calcium sulfate precipitates, but the iron will remain in solution. Remove the flame and tightly insert a stopper through which passes a small stopcock funnel. When the flask is cool or nearly so, pour cold water into the funnel and cautiously open the cock so the water may be drawn into the flask, pouring more water into the funnel as fast as it empties until the solution amounts to 100 to 150 ml. Such precaution to exclude air is hardly necessary in most cases, however, since in the presence of H_2SO_4, the oxidation of ferrous iron is exceedingly slow. It is ordinarily quite sufficient to equalize the internal and external pressures by opening the cock, removing the stopper, and pouring in cold water. Bring the flask under a burette containing 0.05 *N* $KMnO_4$ solution and titrate the iron without delay. With a carbonate which is wholly decomposable without the aid of heat, solution may be accomplished in a flask filled with CO_2, using cold acid, whereby the danger of attack of silicates is lessened if these are present. If the preference is for the $K_2Cr_2O_7$ method of titration, HCl may be used instead of H_2SO_4, in absence of MnO_2. In this case there is, of course, no separation of an insoluble calcium salt, a fact which renders easier the subsequent determination of the iron in any insoluble residue the limestone may yield. The ferrous iron thus found is mostly, if not altogether, that existing as carbonate.[38]

Ferrous Iron In Presence of Carbonaceous Matter[37]

25. Decompose the powder in a flask with diluted H_2SO_4 in an atmosphere of CO_2. With limestones and active agitation no heat need be used, but with dolomites it will be necessary. Quickly filter the solution through asbestos (in

[35] The persulfate method may be employed, if desired.

[36] The separation of manganese with the R_2O_3 precipitate by the use of bromine is not recommended on account of the incompleteness of the precipitation. Separation of manganese by means of ammonium sulfide after the ammonia precipitation is also undesirable on account of the introduction of the reagent and the slimy character of the precipitate.

See also footnote 25 concerning the contamination of magnesium pyrophosphate by manganese pyrophosphate and the need of corrective measures when manganese is present in the material under analysis.

[37] In limestones, the presence of carbonaceous matter renders the exact or even approximate determination of ferrous iron often impossible. Nevertheless, even in its presence acceptable results are sometimes obtainable if the amount of such matter is small and if it does not give with acid a colored solution. Occasionally limestones show films of manganese peroxide which likewise interfere with the determination.

[38] If a determination of ferrous iron in the insoluble residue is desired, see U. S. Geological Survey *Bulletin 700*, p. 265.

an atmosphere of CO_2 if much iron is present), wash the residue and filter a few times with water, and titrate the filtrate at once with 0.05 *N* $KMnO_4$. If it is colored by organic matter, the result may be in error. As above, HCl and titration by $K_2Cr_2O_7$ may be used in absence of MnO_2. In either case it is important to allow the acid to act no longer than is necessary and to filter quickly. A determination of the ferrous iron in the insoluble matter is usually not worth attempting, because of the admixed organic matter.

Available Lime Index

26. (*a*) *Available Lime Index.*—"The available lime index" of high calcium quicklime and hydrated lime designates those constituents which enter into the reaction under the conditions of this specified method. The interpretation of results obtained by the following method shall be restricted by this definition.

(*b*) *Standard Hydrochloric Acid Solution.*—Prepare a solution containing 13.7 ml. of HCl (sp. gr. 1.18) per liter. This solution will be slightly stronger than necessary. Standardize the HCl solution[39] against 0.85 g. of pure, dry Na_2CO_3 using methyl orange as the indicator. Adjust the solution either by the addition of water if too strong, or by the addition of HCl if too weak, so that 0.85 g. of Na_2CO_3 exactly neutralizes 90 ml. of the standard HCl solution. One milliliter of the standard HCl solution is equivalent to 1 per cent CaO.

(*c*) *Rapid Sugar Method.*—Weigh 0.5 g. of the prepared sample (passing a No. 100 (149-micron) sieve) and brush carefully into a 300-ml. Erlenmeyer flask containing about 20 ml. of distilled water (Note 1), and immediately stopper the flask loosely with a rubber stopper. Disperse the sample thoroughly in the water by a swirling motion, heat to boiling, and boil for 2 min. Remove the stopper, add 150 ml. of distilled water at room temperature, and then add 15 g. of granulated sugar (sucrose) (Note 2). Stopper the flask, shake vigorously at intervals for a 5-min. period, and allow to stand for 30 min., but not longer than 1 hr. Add 2 drops of phenolphthalein indicator, wash down the stopper and sides of the flask with distilled water, and titrate (in the original flask) with the standard HCl solution (Note 3).

NOTE 1.—It is particularly important to have a little water in the flask before adding the sample. This is especially true in the case of quicklime, since by adding water on top of a dry charge in a flask there is frequently a tendency for the material to cake and form lumps difficult to completely dissolve in the sugar solution later. On the other hand, if the lime is added to a little water, conditions are favorable to a thorough dispersion of fine particles to produce a more rapid solution. In the case of quicklime, probably some slaking action occurs to facilitate the dispersion and solution.

NOTE 2.—The 15 g. of sugar and the 150 ml. of water used are only approximate amounts. It is not necessary to weigh the sugar each time. A small measure can be employed, such as a spoon which when level full holds slightly more than 15 g. This saves time in running a large number of samples, and just as accurate results are obtained as when the sugar is carefully weighed. A little excess weight of sugar always insures at least a 10 per cent sugar solution.

NOTE 3.—In titrating, first add without shaking about 90 per cent of the acid requirement from a 100-ml. burette. Then shake the flask and finish the titration more carefully, but as rapidly as possible (shaking the flask vigorously), to the first complete disappearance of pink color. Note the reading in per cent and ignore return of color. Unless the operator is familiar with previous analyses of the lime under test, and in cases where the available lime content varies to extremes, it is good practice to run a preliminary test by slow titration to determine the proper amount to add without first shaking the flask. Inasmuch as the method is very simple, this entails no great hardship.

[39] This solution may also be standardized against National Bureau of Standards' standard sample 39 of benzoic acid or standard sample 84 of potassium acid phthalate through an NaOH solution.

Standard Definitions of

TERMS RELATING TO LIME[1]

A.S.T.M. Designation: C 51 - 44

ADOPTED, 1928; REVISED, 1939, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 51; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Lime.—A general term which includes the various chemical and physical forms of quicklime, hydrated lime, and hydraulic lime used for any purpose.

Quicklime.—A calcined material, the major part of which is calcium oxide or calcium oxide in natural association with a lesser amount of magnesium oxide, capable of slaking with water.

Lump Lime.—Quicklime as it comes from the kilns.

Lump Lime Screened.—Lump lime after forking or screening to remove the finer portion.

NOTE.—The portion removed is usually that which will pass a ½-in. sieve.

Pulverized Lime.—Quicklime which will pass a fine sieve of specified size.

NOTE.—The size of the sieve is usually ¼-in.

Hydrated Lime.—A dry powder obtained by treating quicklime with water enough to satisfy its chemical affinity for water under the conditions of its hydration.

NOTE.—It consists essentially of calcium hydroxide or a mixture of calcium hydroxide and magnesium oxide and magnesium hydroxide.

Liming Material.—A general term which includes all of the various chemical and physical forms of lime, limestone, mollusk shells, and marl whose calcium and magnesium content is capable of neutralizing soil acidity.

Air-Slaked Lime.—The product containing various proportions of the oxides, hydroxides, and carbonates of calcium and magnesium which results from the excessive exposure of quicklime to the air.

Calcia.—The chemical compound CaO, calcium oxide.

Magnesia.—The chemical compound MgO, magnesium oxide.

Building or Construction Lime.—A lime whose chemical and physical characteristics and method of processing make it suitable for the ordinary or special construction uses of the product.

Chemical Lime.—A lime whose chemical and physical characteristics and method of processing make it suitable for one or more of the many and varied chemical and industrial uses of the product.

Agricultural Lime.—A lime whose calcium and magnesium content is capable of neutralizing soil acidity.

Available Lime.—Those constituents of a lime which enter into a desired reaction under the conditions of a specific method or process.

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-7 on Lime.

[2] Prior to adoption as standard, these definitions were published as tentative from 1922 to 1928, being revised in 1924 and 1928.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A49.1-1941

Standard Specifications for

GYPSUM[1]

A.S.T.M. Designation: C 22 - 41

ADOPTED, 1925; REVISED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 22; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover gypsum, calcium sulfate combined with two molecules of water in crystalline form and having the approximate chemical formula $CaSO_4 \cdot 2H_2O$.

(*b*) No material may be considered gypsum within the meaning of these specifications that contains less than 64.5 per cent by weight of $CaSO_4 \cdot 2H_2O$.

Size

2. Gypsum may be crushed and ground to the size specified by the purchaser.

Chemical Composition

3. The chemical composition, within the limits prescribed by Section 1, shall be a matter of contract.

Sampling

4. (*a*) *Bulk.*—When gypsum is shipped in bulk, samples of about 5 lb. each shall be taken at regular intervals during the complete loading or unloading of the carrier, in such a way as to accumulate at least 200 lb. of material and to represent correctly the percentages of both the coarse particles and the fines in the shipment. This shall be broken to pass a 1-in. round-hole screen, thoroughly mixed, and reduced by quartering to provide not less than a 1-lb. sample for the laboratory.

(*b*) *Packages.*—When gypsum is shipped in packages, at least 3 per cent of the packages shall be sampled. Samples shall be taken from both the surface and the center of the packages. These samples shall then be broken, mixed, and quartered as directed above.

Laboratory Samples

5. Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for test.

Methods of Testing

6. The chemical analysis and physical properties of gypsum shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26)

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1919 to 1925, being revised in 1920, 1921, 1923, 1924, and 1925.

of the American Society for Testing Materials.[3]

Packing and Marking

7. (*a*) Gypsum may be shipped either in packages or in bulk.

(*b*) When shipped in packages for resale, the following information (Note) shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Description of material, and
Net and gross weights of package.

(*c*) When shipped in bulk, a card containing the required information shall be conspicuously placed in the carrier.

NOTE.—State laws may require additional information.

Inspection

8. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

9. Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications, and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

10. Claims for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A49.3-1940

Standard Specifications for

GYPSUM PLASTERS[1]

A.S.T.M. Designation: C 28 - 40

ADOPTED, 1921; REVISED, 1927, 1930, 1939, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 28; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover four gypsum plasters: namely,
Gypsum ready-sanded plaster,
Gypsum neat plaster,
Gypsum wood-fibered plaster, and
Calcined gypsum for finishing coat.

Calcined Gypsum

2. The term calcined gypsum in these specifications refers to $CaSO_4 \cdot \frac{1}{2}H_2O$, calculated from the SO_3 content.

CHEMICAL AND PHYSICAL PROPERTIES

Gypsum Ready-Sanded Plaster

Description

3. Gypsum ready-sanded plaster is a plastering material in which the predominating cementitious material is calcined gypsum, and which is mixed at the mill with all the constituent parts, including sand, in their proper proportion. Only the addition of water is required to make it ready for use.

Composition

4. The following shall govern the composition of gypsum ready-sanded plaster for the desired coats:

(*a*) *Scratch or First Coat Plaster.*—Gypsum ready-sanded plaster used for scratch or first coat shall contain not more than two-thirds by weight of sand. The other one-third shall contain not less than 60.5 per cent by weight of calcined gypsum. The remainder may consist of materials to control the working quality, the setting time, and the fibering.

(*b*) *Brown or Second Coat Plaster.*—Gypsum ready-sanded plaster used for browning or second coat shall contain not more than three-fourths by weight of sand. The other one-fourth shall contain not less than 60.5 per cent by weight of calcined gypsum. The remainder may consist of materials to control the working quality, the setting time, and the fibering.

Time of Setting

5. Gypsum ready-sanded plaster shall conform to the following requirements as to time of setting:

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1920 to 1921, being revised in 1921.

(*a*) *Scratch or First Coat Plaster.*—Not less than 1½ nor more than 7 hr.

(*b*) *Brown or Second Coat Plaster.*—Not less than 2 nor more than 6 hr.

Tensile Strength

6. Gypsum ready-sanded plaster shall conform to the following requirements as to tensile strength:

(*a*) *Scratch or First Coat Plaster.*—Not less than 125 psi.

(*b*) *Brown or Second Coat Plaster.*—Not less than 75 psi.

Gypsum Neat Plaster

Description

7. Gypsum neat plaster is a plastering material in which not less than 60.5 per cent of the cementitious material is calcined gypsum, and which is mixed at the mill with other materials.

Composition

8. Gypsum neat plaster shall contain not less than 60.5 per cent by weight of calcined gypsum. The remainder may consist of materials to control the working quality, the setting time, and the fibering.

Time of Setting

9. Gypsum neat plaster when mixed with three parts by weight of standard sand shall set in not less than 2 nor more than 32 hr.

Tensile Strength

10. Gypsum neat plaster as tested with two parts of standard sand shall have a tensile strength of not less than 125 psi.

Gypsum Wood-Fibered Plaster

Description

11. Gypsum wood-fibered plaster is a gypsum plaster in which wood fiber is used as an aggregate.

Composition

12. Gypsum wood-fibered plaster shall contain not less than 60.5 per cent by weight of calcined gypsum and not less than 1 per cent by weight of wood fiber made from a nonstaining wood. The remainder may consist of materials to control the working quality and setting time.

Time of Setting

13. Gypsum wood-fibered plaster shall set in not less than 1½ nor more than 8 hr.

Tensile Strength

14. Gypsum wood-fibered plaster shall have a tensile strength of not less than 125 psi.

Calcined Gypsum for Finishing Coat

Description

15. Calcined gypsum for finishing coat may or may not contain retarder, and may be classified in two grades: namely, "white" and "gray."

Fineness

16. Calcined gypsum for finishing coat shall all pass a No. 14 (1410-micron) sieve, and not less than 60 per cent shall pass a No. 100 (149-micron) sieve.[3]

Time of Setting

17. Calcined gypsum for finishing coat, when not retarded, shall set in not less than 20 nor more than 40 min., and when retarded, shall set in not less than 40 min.

Tensile Strength

18. Calcined gypsum for finishing coat shall have a tensile strength of not less than 200 psi.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

SAMPLING

Sampling

19. At least 3 per cent of the packages shall be sampled, and shall be so selected as to be representative of the shipment. Samples shall be taken from both the surface and the center of each package so selected. The material so obtained shall be thoroughly mixed and reduced by quartering to provide not less than a 15-lb. sample for the laboratory.

Laboratory Samples

20. Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for test.

METHODS OF TESTING

Methods of Testing

21. The chemical analysis and physical properties of gypsum plasters shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials.[4]

NOTE.—Distilled water shall be used for conducting all tests.

PACKING AND MARKING

Packing and Marking

22. (*a*) Gypsum plasters shall be dry and free from lumps, and shall be shipped in packages.

(*b*) When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Brand,
Description, and
Net and gross weights of package.

INSPECTION AND REJECTION

Inspection

23. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carrier being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

24. Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications, and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

25. Claim for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A49.4-1940

Standard Specifications for

GYPSUM MOLDING PLASTER[1]

A.S.T.M. Designation: C 59 - 40

ADOPTED, 1929; REVISED, 1930, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 59; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover gypsum molding plaster, a material consisting essentially of calcined gypsum for use in making interior embellishments, cornices, etc.

Composition

2. Gypsum molding plaster shall contain not less than 80 per cent of calcined gypsum ($CaSO_4 \cdot \frac{1}{2}H_2O$).

Time of Setting

3. Gypsum molding plaster shall set in not less than 20 nor more than 40 min.

Tensile Strength

4. Gypsum molding plaster shall have a tensile strength of not less than 200 psi.

Fineness

5. Gypsum molding plaster shall all pass a No. 30 (590-micron) sieve and not less than 90 per cent shall pass a No. 100 (149-micron) sieve.[3]

Sampling

6. At least 3 per cent of the packages shall be sampled and shall be so selected as to be representative of the shipment. Samples shall be taken from both the surface and the center of each packag so selected. The material so obtained shall be thoroughly mixed and reduced by quartering to provide not less than a 15-lb. sample for the laboratory.

Laboratory Samples

7. Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for test.

Methods of Testing

8. The chemical analysis and physical properties of gypsum molding plaster shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials.[4]

NOTE.—Distilled water shall be used for conducting all tests.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1926 to 1929, being revised in 1929.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Packing and Marking

9. (*a*) Gypsum molding plaster shall be dry and free from lumps and shall be shipped in packages.

(*b*) When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Brand,
Description, and
Net and gross weights of package.

Inspection

10. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carrier being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

11. Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications, and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

Standard Specifications for

GYPSUM POTTERY PLASTER[1]

A.S.T.M. Designation: C 60 - 40

ADOPTED, 1929; REVISED, 1930, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 60; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover gypsum pottery plaster, a material consisting essentially of calcined gypsum for use in making pottery molds.

Composition

2. Gypsum pottery plaster shall contain not less than 90 per cent of calcined gypsum ($CaSO_4 \cdot \frac{1}{2}H_2O$).

Time of Setting

3. Gypsum pottery plaster shall set in not less than 20 nor more than 40 min.

Tensile Strength

4. Gypsum pottery plaster shall have a tensile strength of not less than 250 psi.

Fineness

5. Gypsum pottery plaster shall all pass a No. 30 (590-micron) sieve and not less than 94 per cent shall pass a No. 100 (149-micron) sieve.[3]

Sampling

6. At least 3 per cent of the packages shall be sampled and shall be so selected as to be representative of the shipment. Samples shall be taken from both the surface and the center of each package so selected. The material so obtained shall be thoroughly mixed and reduced by quartering to provide not less than a 15-lb. sample for the laboratory.

Laboratory Samples

7. Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for test.

Methods of Testing

8. The chemical analysis and physical properties of gypsum pottery plaster shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[4] except

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1926 to 1929, being revised in 1929.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

that in the measurement of the time of setting and tensile strength the plaster and water shall be mixed in the proportion of 100 g. of plaster to 60 ml. of water.

NOTE.—Distilled water shall be used for conducting all tests.

Packing and Marking

9. (*a*) Gypsum pottery plaster shall be dry and free from lumps and shall be shipped in packages.

(*b*) When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Brand,
Description, and
Net and gross weights of package.

Inspection

10. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carrier being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

11. Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications, and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

12. Claim for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A66.1-1941

Standard Specifications for

KEENE'S CEMENT[1]

A.S.T.M. Designation: C 61 - 40

ADOPTED, 1930; REVISED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 61; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover Keene's cement, anhydrous calcined gypsum the set of which is accelerated by the addition of other materials.

NOTE.—Various grades of Keene's cement of different fineness and setting time are available. These specifications are directly applicable to the grades manufactured for use in the base and finish coats of plastering. Grades intended for use in Scagliola, castings, and other special purposes should conform to the requirements of these specifications in all respects except those for fineness and time of set, which will vary according to the particular use for which the grade is designed.

Time of Setting

2. Keene's cement shall set in not less than 1 nor more than 4 hr.

Tensile Strength

3. The cement shall have a tensile strength of not less than 400 psi.

Fineness

4. The cement shall all pass a No. 14 (1410-micron) sieve, not less than 98 per cent shall pass a No. 40 (420-micron) sieve, and not less than 80 per cent shall pass a No. 100 (149-micron) sieve.[3]

Combined Water

5. The cement shall not show a combined water content of more than 2 per cent.

Sampling

6. At least 3 per cent of the packages shall be sampled and shall be so selected as to be representative of the shipment. Samples shall be taken from both the surface and the center of each package so selected. The material so obtained shall be thoroughly mixed and reduced by quartering to provide not less than a 15-lb. sample for the laboratory.

Laboratory Samples

7. Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for test.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1926 to 1930, being revised in 1928, 1929, and 1930.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Methods of Testing

8. The chemical analysis and physical properties of Keene's cement shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[4] except that in the determination of the time of setting and tensile strength, the consistency used shall be such that a 150-g. modified Vicat needle, described in Section 15 of the Standard Methods C 26, shall give a penetration of 30 ± 2 mm., 20 sec. after release, the measurement being made 5 min. after the addition of the Keene's cement to the gaging water.

NOTE.—A 20-min. mixing and soaking period for the Keene's cement and water with occasional stirring to remove entrained air or gas bubbles is required before filling the molds in the strength determination. The use of 0.1 per cent retarder in determining the testing consistency is necessary when working with quick-setting cements.

Packing and Marking

9. (*a*) Keene's cement shall be dry and free from lumps and shall be shipped in packages.

(*b*) When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Brand,
Description, and
Net and gross weights of package.

Inspection

10. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

11. Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

12. Claims for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPENDIX

FIELD TEST FOR KEENE'S CEMENT

In many instances it is desirable to have a simple test whereby Keene's cement may be identified. Such a test will not indicate the quality of the cement, which should be determined by the laboratory tests enumerated in the body of these specifications, but is of especial value to plasterers, material dealers, and superintendents.

The following procedure is satisfactory for this purpose:

Take a cupful of the material, mix with water to the consistency of a thick paste, and pour upon a plate or piece of glass. Let stand until fairly firm and definite signs of set having begun are manifest. This will be some time less than 2 hr., depending on climatic conditions.

Divide the sample, allowing one half to remain undisturbed. Take the other half and break it down adding a little water, remix, and then allow it to "set up" again on the plate or glass.

If the material is Keene's cement, the remixed portion will, within a few hours, become quite as hard and strong as the portion that was not remixed.

ASA NO.: A65.1-1941

Standard Specifications for
CALCINED GYPSUM FOR DENTAL PLASTERS[1]

A.S.T.M. Designation: C 72 – 40

ADOPTED, 1930; REVISED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 72; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover calcined gypsums having specific properties with reference to time of setting, fineness, and water-carrying capacity, for use in the preparation of dental plasters. Three grades are covered, as follows:

Grade Q (Quick setting),
Grade M (Medium setting), and
Grade S (Slow setting).

Composition

2. Calcined gypsum for use in the preparation of dental plasters shall contain not less than 93 per cent of calcined gypsum ($CaSO_4 \cdot \frac{1}{2}H_2O$).

Time of Setting

3. The calcined gypsum shall conform to the following requirements as to time of setting:

Grade Q.—Not less than 2 nor more than 4 min.

Grade M.—Not less than 6 nor more than 12 min.

Grade S.—Not less than 20 nor more than 40 min.

Tensile Strength

4. The calcined gypsum shall have a tensile strength of not less than 300 psi.

Fineness

5. The calcined gypsum shall all pass a No. 30 sieve (590-micron) and not less than 95 per cent shall pass a No. 100 (149-micron) sieve.[3]

Sampling

6. At least 3 per cent of the packages shall be sampled and shall be so selected as to be representative of the shipment. Samples shall be taken from both the surface and the center of each package so selected. The material so obtained shall be thoroughly mixed and reduced by quartering to provide not less than a 15-lb. sample for the laboratory.

Laboratory Samples

7. Each laboratory sample shall be placed immediately in an airtight con-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1928 to 1930, being revised in 1929 and 1930.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

tainer and shipped to the laboratory for test.

Methods of Testing

8. The chemical analysis and physical properties of calcined gypsum for use in the preparation of dental plasters shall be determined in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[4] except that in the determination of the time of setting and the tensile strength the calcined gypsum and water shall be mixed in the proportion of 100 g. of calcined gypsum to 60 ml. of water. The calcined gypsum shall be allowed to soak in distilled water at 70 F. (21 C.) for 30 sec., and shall then be stirred for 30 sec. and placed immediately in the molds.

Packing and Marking

9. (*a*) Calcined gypsum for use in the preparation of dental plasters shall be dry and free from lumps and shall be shipped in packages.

(*b*) When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

Name of manufacturer,
Brand,
Description, and
Net and gross weights of package.

Inspection

10. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carrier being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

11 Any rejection shall be based upon the specific cause of failure to conform to the requirements of these specifications and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

Rehearing

12. Claim for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A69.1-1942

Standard Specifications for

GYPSUM WALL BOARD[1]

A.S.T.M. Designation: C 36 - 42

ADOPTED, 1934; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 36; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover gypsum wall board, which is designed to be used without the addition of plaster for walls, ceilings, or partitions and affords a surface suitable to receive decoration.

Composition

2. Gypsum wall board shall consist of an incombustible core of gypsum with or without fiber, but not exceeding 15 per cent of fiber by weight, and surfaced with paper or other fibrous material firmly bonded to the core.

Flexural Strength

3. When tested, either face up or face down, in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[3] specimens taken from the gypsum wall board shall carry not less than the following loads without showing a breaking of the bond between the surfacing and the core:

Thickness, in.	Load, lb. Bearing Edges Across Fiber of Surfacing	Load, lb. Bearing Edges Parallel to Fiber of Surfacing
$\frac{1}{4}$	50	24
$\frac{3}{8}$	80	34
$\frac{1}{2}$	105	45

Sampling

4. At least 1 per cent of the number of gypsum wall boards in a shipment, but not less than ten boards, shall be so selected as to be representative of the shipment. Twenty-five per cent of such selected boards, but not less than ten individual boards, shall constitute a sample for purpose of tests. When a shipment consists of more than one car or carrier load, a sample shall be taken from each car or carrier.

Dimensions, Weights, and Permissible Variations

5. (*a*) *Thickness.*—The nominal thickness of gypsum wall board shall be $\frac{1}{4}$ in., $\frac{3}{8}$ in., or $\frac{1}{2}$ in., with permissible variations in the nominal thickness of plus or minus

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1921 to 1925, being revised in 1922, 1924, and 1925. They were adopted in 1925 but withdrawn and replaced in 1933 by C 36 - 33 T which were published as tentative from 1931 to 1934.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

$\frac{1}{64}$ in., and with permissible local variations of plus or minus $\frac{1}{32}$ in. from the nominal thickness. Edges, or edges and ends of $\frac{3}{8}$ in. and $\frac{1}{2}$ in. board may be plain or recessed to receive a joint reinforcing strip; if recessed, the depression shall be not less than 0.02 in.

(*b*) *Width.*—The nominal width of gypsum wall board shall be 24 in., 32 in., 36 in., or 48 in., with a permissible variation of $\frac{3}{32}$ in. under the specified width.

(*c*) *Length.*—The nominal length of $\frac{1}{4}$-in. gypsum wall board shall be from 4 ft. to 12 ft. and of $\frac{3}{8}$-in. and $\frac{1}{2}$-in. board from 4 ft. to 14 ft., inclusive, with permissible variations of plus or minus $\frac{1}{4}$ in. from the specified length.

(*d*) *Weight.*—The weight of gypsum wall board per 1000 sq. ft. shall conform to the following requirements:

Thickness, in.	Weight per 1000 sq. ft., lb. Minimum	Maximum
$\frac{1}{4}$	900	1500
$\frac{3}{8}$	1350	2000
$\frac{1}{2}$	1800	3000

Finish

6. The surfaces of gypsum wall board shall be true and free from imperfections that would render the wall board unfit for use with or without decoration. The edges and ends shall be straight and solid. The corners shall be square with a permissible variation of $\frac{1}{8}$ in. in the full width of the board.

NOTE 1.—Gypsum wall board $\frac{1}{2}$-in. in thickness is available either with square edges or V-tongue and grooved edges. Recessed board is available only with square edges.

NOTE 2.—Gypsum wall board is also available with one surface covered with aluminum or other heat-reflecting type of foil.

Packing and Marking

7. (*a*) Gypsum wall board shall be shipped so as to be kept dry and free from moisture.

(*b*) When shipped for resale, the name of the manufacturer and the brand shall be legibly marked on each board or package.

Inspection

8. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

9. Any rejection shall be based upon failure to conform to the requirements of these specifications and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser. The notice of rejection shall contain a specific statement of the respects in which the boards have failed to conform to the requirements of these specifications.

Rehearing

10. Claims for rehearing shall be valid only if made within 20 working days from the receipt of notice of specific cause for rejection.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A67.1-1942

Standard Specifications for

GYPSUM LATH[1]

A.S.T.M. Designation: C 37 – 42

ADOPTED, 1934; REVISED, 1940, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 37; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover plain, perforated, and other mechanical key types of gypsum lath, which are designed to be used as a base for the reception of gypsum plaster.

Composition

2. Gypsum lath shall consist of an incombustible core of gypsum with or without fiber, but not exceeding 15 per cent of fiber by weight, and surfaced with paper or other fibrous material firmly bonded to the core.

Flexural Strength

3. When tested, either face up or face down, in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[3] specimens taken from the gypsum lath shall carry not less than the following loads without showing a breaking of the bond between the surfacing and the core:

Thickness, in.	Load, lb. Bearing Edges Across Fiber of Surfacing	Load, lb. Bearing Edges Parallel to Fiber of Surfacing
$\frac{1}{4}$	40	16
$\frac{5}{16}$	52	22
$\frac{3}{8}$	60	27
$\frac{1}{2}$	100	40

Sampling

4. At least 1 per cent of the number of gypsum lath in a shipment, but not less than ten lath, shall be so selected as to be representative of the shipment. Twenty-five per cent of such selected lath but not less than ten individual lath, shall constitute a sample for purpose of tests. When a shipment consists of more than one car or carrier load, a sample shall be taken from each car or carrier.

Dimensions, Weights, and Permissible Variations

5. (*a*) *Thickness.*—The nominal thickness of gypsum lath shall be $\frac{1}{4}$ in., $\frac{5}{16}$ in., $\frac{3}{8}$ in., or $\frac{1}{2}$ in., with permissible variations

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1921 to 1925, being revised in 1922 and 1925. They were adopted in 1925, revised 1930, but withdrawn and replaced in 1933 by C 37 – 31 T which was published as tentative from 1931 to 1934.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

in the nominal thickness of plus or minus $\frac{1}{32}$ in., and with permissible local variations of plus or minus $\frac{1}{16}$ in. from the nominal thickness.

(*b*) *Width.*—The nominal width of gypsum lath shall be 16 in., 24 in., or 32 in., with permissible variations of $\frac{1}{4}$ in. under and $\frac{1}{8}$ in. over the specified width.

(*c*) *Length.*—The nominal length of gypsum lath shall be 32 in., 36 in., or 48 in., with permissible variations of $\frac{1}{4}$ in. under and $\frac{1}{8}$ in. over the specified length.

(*d*) *Weight.*—The weight of gypsum lath per 1000 sq. ft. shall conform to the following requirements:

Thickness, in.	Weight per 1000 sq. ft., lb. Minimum	Maximum
$\frac{1}{4}$	900	1500
$\frac{5}{16}$	1125	1750
$\frac{3}{8}$	1350	2000
$\frac{1}{2}$	1800	3000

Finish

6. (*a*) The surfaces of gypsum lath shall be such that they will readily receive and retain gypsum plaster. The edges and ends shall be straight and solid. The corners shall be square with a permissible variation of $\frac{1}{4}$ in. in the full width of the lath. Gypsum lath shall be free of cracks and imperfections that will render them unfit for use.

(*b*) Gypsum lath that have their corners burred or broken shall be considered acceptable provided that the broken portion is not more than 1 in. along either dimension.

NOTE.—Gypsum lath is also available with one surface covered with aluminum or other heat-reflecting type of foil.

Packing and Marking

7. (*a*) Gypsum lath shall be shipped so as to be kept dry and free from moisture.

(*b*) When shipped for resale, the name of the manufacturer and the brand shall be legibly marked on each lath or package.

Inspection

8. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

9. Any rejection shall be based upon failure to conform to the requirements of these specifications and shall be reported to the seller within 10 working days from receipt of the shipment by the purchaser. The notice of rejection shall contain a specific statement of the respects in which the lath have failed to conform to the requirements of these specifications.

Rehearing

10. Claims for rehearing shall be valid only if made within 20 working days from the receipt of notice of specific cause for rejection.

ASA NO.: A68.1-1942

Standard Specifications for

GYPSUM SHEATHING BOARD[1]

A.S.T.M. Designation: C 79 – 42

ADOPTED, 1934; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 79; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover gypsum sheathing board, which is designed to be used as a sheathing in buildings.

Composition

2. Gypsum sheathing board shall consist of an incombustible core of gypsum with or without fiber, but not exceeding 15 per cent of fiber by weight, and surfaced with paper or other fibrous material firmly bonded to the core.

Flexural Strength

3. When tested, either face up or face down, in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[3] specimens taken from the gypsum sheathing boards shall carry not less than the following loads without showing a breaking of the bond between the surfacing and the core:

Thickness, in.	Load, lb. Bearing Edges Across Fiber of Surfacing	Load, lb. Bearing Edges Parallel to Fiber of Surfacing
$\frac{1}{2}$	110	50

Sampling

4. At least 1 per cent of the number of gypsum sheathing boards in a shipment, but not less than ten boards, shall be so selected as to be representative of the shipment. Twenty-five per cent of such selected boards, but not less than ten individual boards, shall constitute a sample for purpose of tests. When a shipment consists of more than one car or carrier load, a sample shall be taken from each car or carrier.

Dimensions, Weights, and Permissible Variations

5. (*a*) *Thickness.*—The nominal thickness of gypsum sheathing board shall be $\frac{1}{2}$ in., with permissible variations in the nominal thickness of plus or minus $\frac{1}{32}$ in., and with permissible local variations of plus or minus $\frac{1}{16}$ in. from the nominal thickness.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1930 to 1934, being revised in 1931.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) *Width.*—The nominal width of gypsum sheathing board shall be 24 in., with a permissible variation of plus or minus $\frac{1}{8}$ in. from the specified width.

(*c*) *Length.*—The nominal length of gypsum sheathing board shall be either 6 ft. 8 in. or 8 ft., with permissible variations of plus or minus $\frac{1}{4}$ in. from the specified length.

(*d*) *Weight.*—The weight of gypsum sheathing board per 1000 sq. ft. shall conform to the following requirements:

Thickness, in.	Weight per 1000 sq. ft., lb. Minimum	Maximum
$\frac{1}{2}$	1800	3000

Finish

6. The edges and ends of gypsum sheathing board shall be straight and solid. The corners shall be square with a permissible variation of $\frac{1}{8}$ in. in the full width of the board. Gypsum sheathing board shall be free of cracks and imperfections that will render them unfit for use.

NOTE.—Gypsum sheathing board is available either with square edges or V-tongue and groove edges.

Packing and Marking

7. (*a*) Gypsum sheathing board shall be shipped so as to be kept dry and free from moisture.

(*b*) When shipped for resale, the name of the manufacturer and the brand shall be legibly marked on each board or package.

Inspection

8. Inspection may be made either at the point of shipment or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

9. Any rejection shall be based upon failure to conform to the requirements of these specifications and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser. The notice of rejection shall contain a specific statement of the respects in which the boards have failed to conform to the requirements of these specifications.

Rehearing

10. Claims for rehearing shall be valid only if made within 20 working days from the receipt of notice of specific cause for rejection.

Standard Specifications for

GYPSUM PARTITION TILE OR BLOCK[1]

A.S.T.M. Designation: C 52 – 41

ADOPTED, 1925; REVISED, 1927, 1933, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 52; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover gypsum partition tile or block, a gypsum building unit in form of tile or block for use in non-load-bearing construction in the interior of buildings and for the protection of columns, elevator shafts, etc., against fire.

NOTE 1.—The words "tile" and "block" are synonymous and are used so as to be in accord with certain freight association nomenclature.

NOTE 2.—Gypsum cored tile, 3 or 4 in. in thickness, may be split and used for furring purposes.

Composition

2. Gypsum tile shall consist of set gypsum with or without aggregates. The weight of combustible materials shall not exceed 15 per cent of the weight of the dry tile.

Compressive Strength

3. (*a*) When tested in accordance with the Standard Methods of Testing Gypsum and Gypsum Products (A.S.T.M. Designation: C 26) of the American Society for Testing Materials,[2] the compressive strength of gypsum tile shall be not less than 75 psi., based on gross area.

(*b*) When completely saturated, the compressive strength shall be not less than one third of the strength required for such tile when dried to constant weight.

Sampling

4. At least 1 per cent of the number of gypsum tile in a shipment, but in no case less than ten tile, shall be so selected as to be representative of the shipment. Twenty-five per cent of such selected tile, but in no case less than ten tile, shall constitute a sample for purpose of tests. In case a shipment consists of more than one car or carrier load, a sample shall be selected from each car or carrier. Samples for test shall be selected at the place of manufacture or at the point of delivery, as specified in the order.

Form

5. Gypsum tile may be solid or cored and shall be rectangular in shape with

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these specifications were published as tentative from 1923 to 1925, being revised in 1924 and 1925.

[2] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

straight and square edges and true surfaces. They may also be of special shape, provided the requirements as otherwise prescribed in these specifications are met. They shall be free from cracks and other imperfections that would render them unfit for use and shall be dried before shipment.

Core Spaces

6. (*a*) The core spaces shall be symmetrically spaced.

(*b*) *Shell Thickness.*—Shell thickness shall be not less than the following:

Thickness of Tile, in.	Side and Edge Shell Thicknesses, in. Circular Cores	Elliptical or Rectangular Cores
3	$\frac{1}{2}$	$\frac{11}{16}$
4	$\frac{1}{2}$	$\frac{13}{16}$
5	$\frac{7}{16}$	1
6	$\frac{1}{2}$	$1\frac{1}{16}$

The sum of the thicknesses of the two side (face) shells plus the thickness of the center vertical web of 6-in. tile shall be not less than 2 in. for tile having circular cores and not less than $2\frac{3}{4}$ in. for tile having elliptical or rectangular cores.

Dimensions

7. (*a*) Gypsum tile may be of any convenient length and height, but in general they shall not exceed 30 in. in length and 12 in. in height. The thickness shall be uniform throughout and within the limits specified in Paragraph (*b*).

(*b*) *Thickness.*—Gypsum tile shall conform to the specified thicknesses within the following permissible variations:

Nominal Size of Tile or Block, in.	Minimum Thickness, in.	Maximum Thickness, in.
$1\frac{1}{2}$ (Furring)	$1\frac{3}{8}$	$1\frac{5}{8}$
2 (Furring)	$1\frac{3}{8}$	$2\frac{1}{8}$
2	2	$2\frac{1}{8}$
3	$2\frac{7}{8}$	$3\frac{1}{8}$
4	$3\frac{7}{8}$	$4\frac{1}{8}$
5	$4\frac{7}{8}$	$5\frac{1}{8}$
6	$5\frac{7}{8}$	$6\frac{1}{8}$

(*c*) *Measurement of Dimensions.*—Over-all dimensions shall be measured between opposite faces of the tile, the greatest measurement observed being taken as the dimension.

Sectional dimensions of cored tile shall be taken 1 in. in from the ends of the tile, the least measurement observed being taken as the dimension.

Shell dimensions shall be measured from the surface of the core space to the normal surface of the tile inside the scoring.

(*d*) *Permissible Variations in Dimensions.*—A variation of $\frac{1}{4}$ in. in the nominal height and $\frac{3}{8}$ in. in the nominal length of the tile is permissible.

Scoring

8. When the surfaces of the tile are scored, the scoring shall not reduce materially the thickness of the shell. Surfaces of the tile shall be such that they afford a suitable bond with plaster.

Marking

9. When gypsum tile are shipped for resale, the manufacturer's "Brand" name shall be shown upon each tile.

Inspection

10. Inspection may be made either at the place of manufacture or at the point of delivery. The inspector representing the purchaser shall have free access to the carriers being loaded for shipment to the purchaser. He shall be afforded all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the loading of the carriers.

Rejection

11. Any rejection shall be based upon

failure to conform to the requirements of these specifications, and shall be reported within 10 working days from the receipt of the shipment by the purchaser. The notice of rejection shall contain a specific statement of the respects in which the tile have failed to meet the requirements of these specifications.

Rehearing

12. Claims for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A70.1-1942

Standard Methods of

TESTING GYPSUM AND GYPSUM PRODUCTS[1]

A.S.T.M. Designation: C 26 - 42

ADOPTED, 1923; REVISED, 1927, 1930, 1933, 1939, 1940, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 26; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the chemical analysis and physical testing of gypsum and gypsum products.

Free Water

2. (*a*) Weigh a sample of not less than 1 lb. of the material as received and spread it out in a thin layer in a suitable vessel. Place in an oven and dry at 113 F. (45 C.) for 2 hr., then cool in an atmosphere free from moisture, and weigh again. The loss of weight corresponds to the free water, and shall be calculated as a percentage of the sample as received.

(*b*) Retain the dried sample in an air-tight container until used for the fineness test (Section 3).

Fineness

3. Determine fineness by sieving a known weight of the dried sample through sieves of the specified sizes (Note). The size of the sample to be used in determining fineness depends upon the particle size of the material. If the material will pass a $\frac{1}{4}$-in. sieve,[3] a 100-g. sample will be sufficient; if the largest particles are more than 1 in. in diameter, use at least a 1000-g. sample. With these limitations the size of sample to be used is left to the discretion of the operator. Shake the sample through each sieve with as little abrasion as possible. Weigh the amount of material retained on each sieve and calculate the fineness expressed as a percentage of the weight of the original sample.

NOTE.—The sizes of the sieves to be used are given in the specifications of the American Society for Testing Materials covering the particular product in question.

CHEMICAL ANALYSIS

Preparation of Sample

4. Weigh a sample of not less than 1 lb. of the material as received and spread it out in a thin layer in a suitable vessel. Place in an oven and dry at 113 F. (45 C.) for 2 hr., then cool in an

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these methods were published as tentative from 1919 to 1923, being revised in 1920, 1921, and 1923.

[3] Detailed requirements for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

atmosphere free from moisture. Reduce the sample to pass a No. 60 (250-micron) sieve,[3] using extreme care not to expose unduly the material to moisture or to overheating. Thoroughly remix the ground sample, and store it in an air-tight container until used.

COMPLETE PROCEDURE

Combined Water

5. Place 1 g. of the sample in a covered crucible and dry to constant weight at 420 to 445 F. (215 to 230 C.). Calculate the loss of weight to percentage of sample as received, and report as combined water.

Carbon Dioxide

6. Place the residue, obtained after drying as described in Section 5, in a suitable flask and dissolve it in diluted HCl (not stronger than 1:4) in such a way that the gas evolved, after being freed from water vapor by calcium chloride or sulfuric acid, can be collected in either soda-lime or caustic potash and weighed. Boil the solution for 1 min., and pass a current of CO_2-free air through the apparatus for 30 min. The increase of weight of the soda-lime or caustic potash corresponds to the weight of carbon dioxide. Calculate the CO_2 to percentage of sample as received.

Silicon Dioxide and Insoluble Matter

7. Place 0.5 g. of the sample in a porcelain casserole. Add about 25 ml. of HCl (1:5), and evaporate to apparent dryness on a hot plate. Cool, and add enough HCl (sp. gr. 1.19) to wet thoroughly. Add about 10 ml. of water, boil, filter, and wash. Put the filtrate back in the same casserole. Evaporate it to dryness and heat to about 250 F. (120 C.) for 1 hr. and then cool. Add enough HCl (sp. gr. 1.19) to wet thoroughly. Add about 25 ml. of water, boil, filter, and wash. Transfer the two papers containing the two precipitates to the same crucible, ignite, and weigh. Calculate the SiO_2 and insoluble matter to percentage of sample as received.

Iron and Aluminum Oxides

8. To the filtrate obtained as described in Section 7, add a few drops of HNO_3, and boil to insure oxidation of the iron. Add 2 g. of NH_4Cl previously dissolved in water. Make alkaline with NH_4OH. Digest hot for a few minutes until the precipitate coagulates. Filter, wash, ignite the precipitate, and weigh as $Fe_2O_3 + Al_2O_3$. Calculate the iron and aluminum oxides to percentage of sample as received. This precipitate may be further treated to separate the two oxides, but this is generally unnecessary.

Lime

9. (*a*) To the filtrate obtained as described in Section 8, add 5 g. of $(NH_4)_2C_2O_4$ dissolved in water. Digest hot for 30 min., making sure that the solution is always alkaline with NH_4OH. Filter, wash, and ignite to constant weight in a platinum crucible over a strong blast. Calculate the CaO to percentage of sample as received.

(*b*) *Alternative Method.*—To the filtrate obtained as described in Section 8, add 5 g. of $(NH_4)_2C_2O_4$ dissolved in water. Digest hot for 30 min., making sure that the solution is always alkaline with NH_4OH. Filter and wash. Transfer the precipitate to a beaker, and wash the filter paper with hot diluted H_2SO_4, catching the washings in the same beaker. Heat gently to complete solution, adding more H_2SO_4 if necessary. While still warm, titrate with a solution of $KMnO_4$ containing 5.6339 g. per liter, until the pink color is permanent. The number of milliliters of $KMnO_4$ used gives directly the percentage of lime in the dried sample.

Recalculate the CaO to percentage of sample as received.

Magnesium Oxide

10. To the filtrate obtained as described in Section 9 (*a*) or (*b*), add enough water to give a total volume of about 600 ml. Cool, and add 10 ml. of NH_4OH and 5 g. $NaNH_4HPO_4$ dissolved in water. Stir until precipitate begins to form. Let stand over night. Filter, wash with NH_4NO_3 (2.5 per cent). Ignite and weigh. Multiply this weight by 0.36207 to find the weight of MgO. Calculate the MgO to percentage of sample as received.

Sulfur Trioxide

11. Dissolve 0.5 g. of the sample in 50 ml. of HCl (1:5). Boil. Add 100 ml. of boiling water, and continue boiling for 5 min. Filter immediately and wash thoroughly with hot water. Boil, and while boiling, add slowly 20 ml. of a boiling solution of $BaCl_2$ (10 per cent). Digest hot for 1 hr., or until the precipitate settles. Filter and wash. Dry carefully. Ignite over a bunsen burner at the lowest heat possible until the filter paper is burned off. Ignite at bright red heat for 15 min., and weigh. Multiply this weight by 0.34297 to determine the weight of SO_3. Calculate the SO_3 to percentage of sample as received.

Sodium Chloride

12. Dissolve 1 g. of the sample, in boiling water, filter, and wash with 250 ml. of boiling water. Add two or three drops of K_2CrO_4 to the filtrate and titrate with $AgNO_3$ (0.05 *N*). One milliliter of $AgNO_3$ is equivalent to 0.002923 g. of sodium chloride. Calculate the NaCl to percentage of sample as received.

Report

13. Report the results obtained in the analysis as follows:

	Per cent
Free water	.....
Combined water	.....
Carbon dioxide, CO_2	.....
Silicon dioxide (SiO_2) and insoluble matter	.....
Iron and aluminum oxides, $Fe_2O_3 + Al_2O_3$	.....
Lime, CaO	.....
Magnesium oxide, MgO	.....
Sulfur trioxide, SO_3	.....
Sodium chloride, NaCl	.....
Total	100.00±

NOTE 1.—Since it is frequently advisable to recalculate the results obtained in the chemical analysis in order that they may be more enlightening, the following is submitted for consideration:

(*a*) Multiply percentage of MgO by 2.0912 to find percentage of $MgCO_3$.

(*b*) Multiply the percentage of MgO by 1.0914 to find the percentage of CO_2 as $MgCO_3$.

(*c*) Deduct CO_2 as $MgCO_3$ from the CO_2 determined.

(*d*) Multiply the CO_2 remaining by 2.2742 to find percentage of $CaCO_3$.

(*e*) Add together the percentage of SiO_2, $Fe_2O_3+Al_2O_3$, $MgCO_3$, and $CaCO_3$, and report in the aggregate.

(*f*) Multiply the percentage of $CaCO_3$ by 0.56031 to find the percentage of CaO as $CaCO_3$.

(*g*) From the total percentage of CaO, deduct the percentage of CaO as $CaCO_3$. The remainder may be called "available CaO."

(*h*) The "available CaO" should bear to the SO_3 a ratio of 0.6991 to 1. Determine which (if either) is in excess.

(*i*) If the CaO is in excess, multiply the SO_3 by 0.6991, and subtract the result from the "available CaO." The remainder is reported as "excess CaO."

(*j*) If the SO_3 is in excess, multiply the "available CaO" by 1.4304 and subtract the result from the SO_3. The remainder is reported as "excess SO_3."

(*k*) Add together the "available CaO," and the SO_3, and subtract the "excess CaO" or "excess SO_3." The remainder is $CaSO_4$.

(*l*) If the $CaSO_4$ is present as $CaSO_4 \cdot \frac{1}{2}H_2O$, the percentage of $CaSO_4$ should bear to the percentage of combined water a ratio of 15.12 to 1. Determine which (if either) is in excess.

(*m*) If the $CaSO_4$ is in excess, some of it is present in the anhydrous form. Multiply the

percentage of combined water by 15.12 to find the percentage of $CaSO_4$ as $CaSO_4 \cdot \frac{1}{2}H_2O$. The difference between the total $CaSO_4$ and the percentage of $CaSO_4$ as $CaSO_4 \cdot \frac{1}{2}H_2O$, is the $CaSO_4$ in the anhydrous form.

(*n*) If the water is in excess, some of the $CaSO_4$ is present as gypsum. Let x = percentage of $CaSO_4 \cdot \frac{1}{2}H_2O$, and y = percentage of $CaSO_4 \cdot 2H_2O$.

Then:

$x + y$ = percentage of $CaSO_4$ (as found in *k*) + percentage of water.

$0.06206x + 0.2093y$ = percentage of combined water.

Solve these equations for x and y. Report x as percentage of "calcined gypsum," $CaSO_4 \cdot \frac{1}{2}H_2O$. Report y as percentage of gypsum, $CaSO_4 \cdot 2H_2O$.

NOTE 2.—Having made the calculations listed in Note 1, the results may be reported as follows:

	Per cent
Gypsum, $CaSO_4 \cdot 2H_2O$	.....
Calcined gypsum, $CaSO_4 \cdot \frac{1}{2}H_2O$	.....
Anhydrite $CaSO_4$	.....
Excess CaO or Excess SO_3	.....
Sodium chloride, NaCl	.....
Other ingredients	.....
Total	100.00±

NOTE 3.—The presence of the different forms of $CaSO_4$ may be corroborated by a microscopic examination.

ALTERNATIVE PROCEDURE FOR CALCIUM SULFATE BY AMMONIUM ACETATE METHOD[4]

Nature of Test

14. This procedure is intended for determining calcium sulfate in gypsum and gypsum products by extraction with ammonium acetate solution, and may be used as an alternative method to the complete procedure described in Sections 2 to 13.

Reagents

15. (*a*) *Ammonium Acetate Solution.*—Dissolve 454 g. of c.p. ammonium acetate in 2 liters of water. Add sufficient NH_4OH to make the solution distinctly ammoniacal, using phenolphthalein as the indicator.

(*b*) *Ammonium Hydroxide Wash Solution.*—Dilute 100 ml. of NH_4OH (sp. gr. 0.90) to 1 liter.

(*c*) *Filter Aid.*—Analytical grade diatomaceous silica.

Procedure Using Gooch Crucible

16. (*a*) Weigh rapidly approximately 4 g. (Note 1) of the well-mixed sample and transfer to a 600-ml. beaker.

NOTE 1.—All weighings shall be made to 0.001 g., except that weights of crucibles and of their contents shall be determined to 0.0001 g.

(*b*) Without delay, weigh 1 g. of the well-mixed sample in a tared weighing bottle having a ground-glass stopper. Dry the sample and weighing bottle to constant weight at 45 C. (Note 2), and calculate the percentage loss in weight at 45 C. (largely uncombined water) as follows:

$$\text{Loss in weight at 45 C., per cent} = \frac{A - B}{C} \times 100$$

where:

A = original weight of sample and weighing bottle,

B = weight of sample and weighing bottle dried to constant weight at 45 C., and

C = original weight of sample.

Calculate the weight of the 4-g. sample (Paragraph (*a*)) corrected for loss on heating to constant weight at 45 C.

If the percentage by weight of combined water held by the calcium sulfate is desired, heat the sample and weighing bottle to constant weight at 220 C. (Note 2), and calculate the percentage of combined water as follows:

$$\text{Combined water, per cent} = \frac{B - D}{B - E} \times 100$$

[4] This procedure was prepared by L. S. Wells and W. F. Clarke, National Bureau of Standards, and modified by B. E. Kester, United States Gypsum Co.

where:

B = weight of sample and weighing bottle dried to constant weight at 45 C.,
D = weight of sample and weighing bottle dried to constant weight at 220 C., and
E = weight of weighing bottle.

NOTE 2.—Stopper weighing bottles immediately upon removal from the oven in order to prevent absorption of moisture from the air upon cooling.

(*c*) To the contents of the 600-ml. beaker (Paragraph (*a*)), add 350 ml. of the ammonium acetate solution, and stir the mixture thoroughly so as to loosen all of the solid matter from the bottom of the beaker. Add 0.2000 g. of redried diatomaceous silica to the mixture, heat the beaker and contents to 70 C. on a steam bath, and maintain at that temperature for 30 min., while stirring frequently. During the heating, keep the solvent ammoniacal by additions of NH_4OH and phenolphthalein, if indicated. (Meanwhile, heat a supply of the ammonium acetate solution to 70 C., keeping it also distinctly ammoniacal.) Filter the mixture, with suction, through a tared Gooch crucible, stirring frequently during filtration to keep the diatomaceous earth suspended in the liquid. Wash the Gooch crucible containing the residue with five 10-ml. portions of the warm acetate solution, draining thoroughly after each washing. Wash in the same manner with eight 10-ml. portions of the NH_4OH wash solution. Care shall be exercised to wash the upper walls of the Gooch crucible. Drain the crucible dry with suction, place in an oven at 70 C., and dry to constant weight (Note 3). Allow the crucible to cool in a desiccator before weighing.

NOTE 3.—Avoid overheating in all oven drying of ammonium acetate residues; that is, place crucibles well away from the heating elements. This is of particular importance for samples high in impurities, as these impurities often have water of hydration that is lost on local overheating.

(*d*) Calculate the percentage of $CaSO_4 \cdot XH_2O$ on the basis of the sample dried to constant weight at 45 C., as follows:

$$CaSO_4 \cdot XH_2O, \text{ per cent} = \frac{F - (G - H)}{F} \times 100$$

where:

F = weight of sample, corrected for loss on heating to constant weight at 45 C.,
G = weight of dried crucible and contents, and
H = weight of crucible plus diatomaceous silica used as filter aid.

Procedure Using Tared Filter Papers[5]

17. (*a*) Dry a quarter-folded, 11-cm., quantitative filter paper overnight at 70 C. in a wide-form, glass-stoppered, 30 by 60-mm. weighing bottle. After drying, cool the weighing bottle and paper in a desiccator, and weigh.

(*b*) Treat the sample exactly as described in Section 16 prior to the filtration. Filter the mixture by gravity through an ordinary 7-cm. glass funnel, stirring frequently during filtration to keep the diatomaceous silica suspended in the liquid. Wash the filter paper and residue with five 10-ml. portions of warm acetate solution, draining thoroughly after each washing. Wash in the same manner with eight 10-ml. portions of the NH_4OH wash solution. After final draining replace the paper and residue in the weighing bottle, and dry at 70 C. to constant weight (see Note

[5] This procedure is suggested where several samples are to be analyzed at once. It has been found that gravity filtration on six samples will proceed as rapidly as it is possible to handle them.

3 under Section 16 (*c*)). Cool the weighing bottle, paper, and residue in a freshly prepared desiccator before weighing; this is essential, due to the hygroscopic character of paper.

(*c*) Calculate the percentage of $CaSO_4 \cdot XH_2O$ as described in Section 16 (*d*), substituting the weight of the weighing bottle and filter paper for the weight of the crucible.

PHYSICAL TESTS

Precautions for Physical Tests

18. Gypsum products are peculiar in that their properties are very greatly affected by the small amounts of impurities which may be introduced by careless laboratory manipulation. In order to obtain concordant results, it is therefore absolutely essential to observe the following precautions:

(*a*) All apparatus shall be kept thoroughly clean. Especially shall all traces of set plaster be removed.

(*b*) Distilled water, free from chlorides and sulfates, shall be used exclusively.

(*c*) Standard sand shall be used exclusively consisting of a natural silica sand from Ottawa, Ill. It shall be prepared for use by washing once with HCl (1:4) and four times with distilled water, and then drying.

NORMAL CONSISTENCY OF GYPSUM PLASTER

NOTE.—An accurate method for determining normal consistency is the most important step in the standardizing of physical methods for testing cementitious materials.

Apparatus

19. (*a*) *Modified Vicat Apparatus.*—The modified Vicat apparatus (Fig. 1) shall consist of a bracket, *A*, bearing a movable brass rod, *B*, 6.3 mm. in diameter and of suitable length to fit the Vicat bracket. On the lower end of the rod shall be attached a plunger, *C*, 19.0 mm. in diameter and 44.4 mm. in length, made of aluminum tubing. The total weight of the rod with plunger shall be 50 g. This total weight may

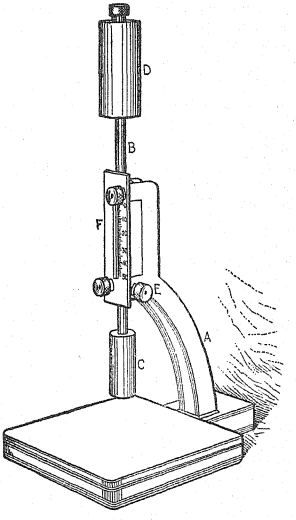

FIG. 1.—Modified Vicat Apparatus.

be increased by means of a weight, *D*, screwed into the rod. The rod can be held in any desired position by a screw *E*. The rod shall have a mark midway between the ends which moves under a scale, *F*, graduated in millimeters, attached to the bracket, *A*.

(*b*) *Mold.*—The conical ring mold shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 7 cm. at the base and 6 cm. at the top and a height of 4 cm.

(*c*) *Base Plate.*—The base plate for supporting the ring mold shall be of plate glass and about 10 cm. square.

Procedure

20. (*a*) The plunger, mold, and base plate of the modified Vicat apparatus shall be cleaned. A thin coat of vaseline or other suitable lubricant shall be applied to the upper surface of the base plate in order to prevent leaks during the test.

(*b*) A 200-g. sample shall be sifted into a known volume of water to which has been previously added 0.2 g. of commercial retarder. After allowing the sample to soak for 2 min. the mixture shall be stirred for 1 min. to an even fluidity. This sample shall then be poured into the ring mold, worked slightly to remove air bubbles and then struck off flush with the top of the mold. The plunger of the modified Vicat apparatus shall then be wet and lowered to the surface of the sample at approximately the center of the mold. The scale shall be read and the plunger released immediately. After the rod has settled, the scale shall be read again. Readings are reproducible on a retarded mix, and therefore, in order to eliminate error, two or three determinations should be made on each mix, care being taken to have the mold completely filled and the plunger clean and wet.

Normal Consistency

21. (*a*) *Normal Consistency, Calcined Gypsum.*—Calcined gypsum shall be considered of normal consistency when a penetration of 30 ± 2 mm. is obtained when tested in accordance with Section 20, weight of rod and plunger for this determination to be 50 g. Normal consistency shall be expressed as the number of milliliters of water required to be added to 100 g. of the gypsum.

(*b*) *Normal Consistency, Gypsum Mixtures.*—Sanded gypsum mixtures and gypsum wood-fiber plaster shall be considered of normal consistency when a penetration of 20 ± 3 mm. is obtained when tested in accordance with Section 20, weight of rod and plunger for these determinations to be 150 g. Normal consistency shall be expressed as the number of milliliters of water required to be added to 100 g. of the mixture.

WATER-CARRYING CAPACITY

Water-Carrying Capacity

22. The water-carrying capacity is the amount of water, calculated as percentage by weight of the dry material, that is necessary to bring the mixture to normal consistency.

DRY BULK

Procedure

23. Dry bulk is the volume in cubic centimeters occupied by 100 g. of dry material.[6] A No. 10 (2000-micron) sieve[3] shall be placed above a No. 20 (840-micron) sieve[3] and the two sieves held at a height of 12 in. (30 cm.) above a perpendicular-sided receptacle of known volume (about 400 cu. cm.). The material under test shall be placed on top of the No. 10 sieve and passed through the No. 10 and No. 20 sieves, filling the receptacle. The material shall be struck off flush with the top of the receptacle and the net weight obtained of the contents in grams. The average result of three tests shall be obtained according to this method and reported in cubic centimeters per 100 g.

WET BULK

Wet Bulk

24. Wet bulk is the volume in cubic centimeters occupied by a mixture of

[6] Dry bulk is expressed as the volume in cubic centimeters occupied by 100 g. of dry material instead of "grams per 100 cu. cm.," since bulk is understood to mean volume per unit weight rather than weight per unit volume.

100 g. of dry material mixed with water to normal consistency.

TIME OF SETTING

Apparatus

25. (*a*) *Vicat Apparatus.*—The Vicat apparatus (Fig. 2) shall consist of a frame *A*, bearing a movable rod *B*, weighing 300 g., one end *C*, the plunger end, being 1 cm. in diameter for a distance of at least 5 cm., the other end having a removable needle *D*, 1 mm. in diameter and 5 cm. in length. The rod *B* shall be reversible, and can be held in any desired position by a screw *E*, and shall have an adjustable indicator *F* which moves over a scale (graduated in millimeters) attached to the frame *A*. The paste is held in a rigid conical ring *G*, resting on a glass plate *H* about 10 cm. square. The ring shall be made of a noncorroding, nonabsorbent material and shall have an inside diameter of 7 cm. at the base, 6 cm. at the top, and a height of 4 cm.

(*b*) In addition to the above, the Vicat apparatus shall conform to the following requirements:

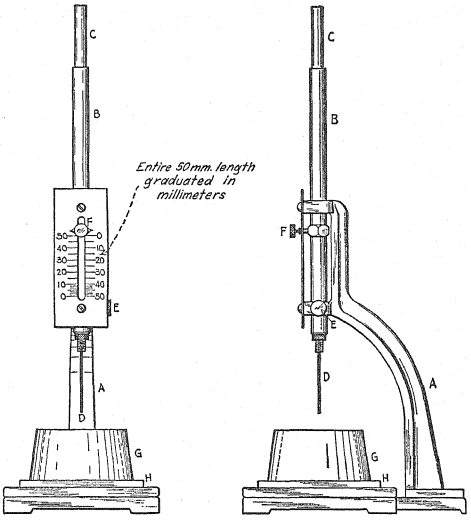

FIG. 2.—Vicat Apparatus.

Weight of plunger	300 ± 0.5 g. (0.661 lb. ± 3 grains)
Diameter of larger end of plunger.	1 ± 0.005 cm. (0.394 ± 0.002 in.)
Diameter of needle	1 ± 0.05 mm. (0.039 ± 0.002 in.)
Inside diameter of ring at bottom	7 ± 0.3 cm. (2.75 ± 0.12 in.)
Inside diameter of ring at top	6 ± 0.3 cm. (2.36 ± 0.12 in.)
Height of ring.	4 ± 0.1 cm. (1.57 ± 0.04 in.)
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm. at all points, shall not show a deviation at any point greater than 0.25 mm.

Procedure

26. (*a*) *All Calcined Gypsum Products, Except Gypsum Neat Plaster.*—A 200-g. sample (Note) shall be mixed with enough water to make a paste of normal consistency as described in Sections 19 to 21. The paste shall be placed in the conical ring and, after completely filling the ring, the paste shall be tested for final set with a Vicat needle. When conducting the test, the needle shall be allowed to sink into the paste at frequent intervals. After each penetration, the needle shall be wiped clean, and the paste moved slightly so that the needle will not strike the same place twice. The frequency of the penetration will depend upon the character of the material. If the sample is not retarded, it shall be tested every 2 min. until nearly set, and then every 1 min. If the sample is retarded, it shall be tested at such intervals as are necessary to determine whether it complies with the requirements for time of setting for the product tested. Set shall be considered complete when the needle no longer penetrates to the bottom of the paste. The elapsed time in minutes from the time when the sample was first added to the water to the time when set is complete shall be recorded as the time of setting of the sample.

NOTE.—When the material to be tested is gypsum ready-mixed sanded plaster, a 300-g. sample shall be mixed to normal consistency for sanded gypsum mixture.

(*b*) *Gypsum Neat Plaster.*—Gypsum neat plaster shall be tested for time of setting as mixed with three parts by weight of standard sand that has been washed and dried in accordance with the procedure described in Section 18 (*c*). A 100-g. sample of the gypsum neat plaster and 300 g. of the standard sand shall be mixed dry, and then sufficient water added to produce a mixture of normal consistency for sanded gypsum mixtures as described in Section 21 (*b*). The mortar shall be placed in the conical rings and tested for time of setting as described in Paragraph (*a*). Until set, the test specimens shall be stored in a cabinet at a temperature of not less than 68 F. (20 C.) nor more than 72 F. (22.2 C.) in an atmosphere having a relative humidity of not less than 85 nor more than 100 per cent. The specimens shall not be tested with the Vicat needle until they show evidence of stiffening or setting. Excessive penetration of the mix with the needle tends to accelerate the setting time. For plaster setting in less than 5 hr. the setting time shall be determined to the nearest 15-min. interval, and for plaster setting in more than 5 hr., to the nearest 30-min. interval.

TENSILE STRENGTH

Apparatus

27. (*a*) *Molds.*—The molds for making test specimens shall be made of noncorroding material and shall have sufficient material in the sides to prevent spreading during molding. The dimensions of the briquet molds shall conform to the following requirements: width of mold, between inside faces, at waist line of briquet, 1 in. with permissible variations of plus or minus 0.01 in. for old molds and plus or minus 0.005 in. for new molds; thickness of new mold, measured at point of greatest thickness on either side of mold at waist line, 1 in. with permissible variations of plus 0.004 in. and minus 0.002 in.

(*b*) *Testing Machine.*—Any form of universal testing machine suitable for making tension tests may be used.

Test Specimen

28. (*a*) *All Calcined Gypsum Products Except Gypsum Neat Plaster.*—A

500-g. sample (Note) shall be mixed to normal consistency in accordance with Sections 19 to 21 and cast in a briquet mold of the shape and size shown in Fig. 3. Before being filled, the molds shall be oiled with a thin film of mineral oil. The briquet specimens shall not be cast successively, but instead, the containing vessel shall be moved back and forth over the molds while pouring continuously. The briquets shall be worked slightly with the point of the

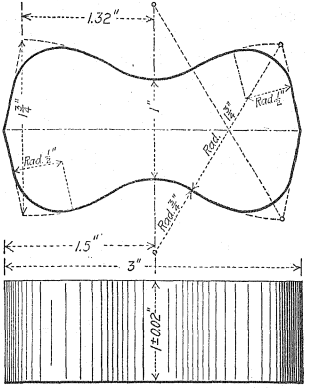

FIG. 3.—Briquet Specimen for Tensile Strength Test.

trowel to remove air bubbles and leveled off flush with the top of the mold. The briquet shall be retained not less than 24 hr. in the mold in moist air until thoroughly hardened. The specimens shall then be removed from the mold and dried at not less than 70 F. (21.1 C.) nor more than 100 F. (37.8 C.) in an atmosphere having a relative humidity of not more than 50 per cent. The specimen shall be weighed at 1-day intervals until the weight has become constant to within 0.1 per cent.

NOTE.—When the material to be tested is gypsum ready-mixed sanded plaster, a sample of not less than 750 g. shall be used and mixed to normal consistency for sanded gypsum mixture.

(*b*) *Gypsum Neat Plaster.*—Gypsum neat plaster, both fibered and unfibered, shall be tested for tensile strength as mixed with two parts of standard sand; fibered plaster shall be sieved through a No. 6 (3360-micron) sieve to remove the major portion of the long fibers present. A 250-g. sample of the gypsum neat plaster and 500 g. of standard sand shall be mixed dry, and then sufficient water added to produce a mixture of normal consistency in accordance with Section 21 (*b*). The mortar shall be cast into the molds as described in Paragraph (*a*), except that the molds shall be so filled as to allow a slight excess of the mortar to extend above the top of the molds. After the mortar has set, the excess mortar shall be screeded from the top of the molds with a broad knife or similar implement. The mortar briquet specimens shall be dried as described in Paragraph (*a*).

Procedure

29. As soon as the briquet specimens have been dried (Section 28) their tensile strengths shall be determined.

Report

30. The average tensile strength shall be reported as the tensile strength of the material, except that if the strengths of one or two of the briquets vary more than 15 per cent from the average of the five, they shall be discarded and the tensile strength shall be reported as the average of the remaining specimens. In case the tensile strengths of three or more briquet specimens vary more than 15 per cent from the average, the results shall be discarded and the test repeated.

COMPRESSIVE STRENGTH

Test Specimens

31. A 1500-g. sample shall be mixed to normal consistency as described in Sections 19 to 21, and cast into five 2-in. split-cube molds set plumb upon metal or glass plates. The cubes shall not be cast successively, but instead, the containing vessel shall be moved back and forth over the molds while pouring continuously. The cubes shall be worked slightly with the point of the trowel to remove air bubbles, and leveled off flush with the top of the molds. The cubes shall be retained not less than 24 hr. in the molds in moist air until thoroughly hardened. The specimens shall then be removed from the molds and dried at a temperature of not less than 70 F. (21.1 C.) nor more than 100 F. (37.8 C.) in an atmosphere having a relative humidity of not more than 50 per cent. The specimens shall be weighed at 1-day intervals until the weight has become constant to within 0.1 per cent.

Procedure

32. As soon as the cube specimens have been dried (Section 31) their compressive strengths shall be determined.

Report

33. The average compressive strength shall be reported as the compressive strength of the material, except that if the strengths of one or two of the cubes vary more than 15 per cent from the average of the five, they shall be discarded and the compressive strength shall be reported as the average of the remaining specimens. In case the tensile strengths of three or more cubes vary more than 15 per cent from the average, the results shall be discarded and the test repeated.

DETERMINATION OF SAND IN SET PLASTER

Ammonium Acetate Method

34. Any method for the determination of the sand content of set gypsum plaster requires for accurate results the following determinations:

(*a*) Determination of the percentage of insoluble matter in the sand used with the plaster,

(*b*) Determination of the percentage of insoluble matter in the gypsum neat plaster, and

(*c*) Determination of the percentage of insoluble matter in the sanded calcined plaster.

NOTE.—If samples of the original gypsum neat plaster and the sand are not available, an approximation of the insoluble matter may be obtained by use of this method on plaster and sand from the same sources as those from which the plaster to be analyzed was originally prepared.

Sampling

35. Where plaster to be tested is part of a two-coat or three-coat plastering operation, the sample for analysis shall be taken from that portion of the entire plaster sheet which comprises the single coat being tested. Succeeding coats of plaster shall be separated by use of a stiff putty knife or similar implement. At least 500 g. shall be taken as a sample, the sample preferably being obtained from different sections of the wall or ceiling under examination.

Procedure

36. (*a*) In a clean porcelain mortar, grind the set-plaster sample to the size of the largest sand particles present, or smaller, so that approximately 100 per cent of the sample will pass a No. 8 (2380-micron) sieve. Fine grinding makes solution of the gypsum faster. Place about 200 g. of the ground sample in a porcelain casserole or evaporating dish, and calcine on a sand bath. Stir

the sample continuously with a thermometer during the heating, and adjust the rate of heating so that 20 to 30 min. will be required to raise the temperature of the sample to 320 ± 9 F. (160 ± 5 C.). Cool the sample to room temperature.

(*b*) After cooling, weigh accurately 20 ± 0.05 g. of the calcined sample into a 600-ml. beaker. Add 300 to 350 ml. of ammonium acetate (25 per cent), which should be slightly alkaline to litmus paper. If acidic, add a few milliliters of diluted NH_4OH (1 per cent) to the stock solution of ammonium acetate to render it slightly alkaline prior to the addition to the test sample.

(*c*) Warm the suspension to a temperature of 158 ± 9 F. (70 ± 5 C.) and stir continuously for 20 to 30 min. Filter the warm suspension with the aid of suction through a small Büchner funnel or Gooch crucible in which an asbestos mat or filter paper has previously been formed, the funnel and mat having been dried at 230 F. (110 C.) to constant weight within 0.01 g. Refilter the first 100 ml. of the filtrate. Wash the sand remaining in the beaker onto the filter with an additional 100 ml. of warm ammonium acetate solution. Wash the beaker and residue with 200 to 300 ml. of water, dry the funnel and sand at 212 F. (100 C.) to constant weight. Subtract the weight of the residue from the original weight of the sample to obtain the weight of the insoluble matter.

(*d*) *Percentage of Insoluble Matter in Plaster.*—Multiply the weight of the insoluble matter obtained in Paragraph (*c*) by 5 to obtain the percentage of insoluble matter in the sanded plaster.

(*e*) *Percentage of Insoluble Matter in Sand.*—Determine the weight of insoluble matter in the sand as described in Paragraphs (*a*) to (*c*), except that no grinding of the sample is necessary. Multiply the weight of the insoluble matter obtained by 5 to obtain the percentage of insoluble matter in the sand.

(*f*) *Percentage of Insoluble Matter in Gypsum Neat Plaster.*—Determine the weight of insoluble matter in the gypsum neat plaster as described in Paragraphs (*a*) to (*c*), except that only a 5-g. sample is required and no grinding of the sample is necessary. Multiply the weight of the insoluble matter obtained by 20 to obtain the percentage of insoluble matter in the gypsum neat plaster.

Calculation

37. (*a*) The percentage of sand in the sanded plaster shall be calculated as follows:

$$X = \frac{(C - B)100}{A - B}$$

where:

X = percentage of sand in sanded plaster,
A = percentage of insoluble matter in the sand,
B = percentage of insoluble matter in the gypsum neat plaster, and
C = percentage of insoluble matter in the sanded plaster.

(*b*) To express the results as a ratio of the parts of sand per part of plaster by weight, the following formula may be used:

$$\text{Ratio of sand to plaster} = \frac{X}{100 - X}$$

NOTE.—The results obtained by the above procedure indicate the amount of sand originally mixed with the gypsum neat plaster before it had been gaged with water or set.

WOOD-FIBER CONTENT IN WOOD-FIBER GYPSUM PLASTER

Procedure

38. (*a*) A 100-g. sample of wood-fiber plaster, prepared as described in Section 4

shall be placed on a No. 30 (590-micron) sieve nested over a No. 100 (149-micron) sieve. The plaster on the No. 30 sieve shall then be washed with a stream of cold water, removing the No. 30 sieve when the fiber on it is practically or entirely free of plaster. The material on the No. 100 sieve shall next be washed until the bulk of the plaster has been washed through the sieve and the residue is mainly fiber. The material retained on the No. 100 sieve shall then be transferred to a 3-qt. vitreous enamel lipped pan, adding the charge on the No. 30 sieve if the fiber contains any adhering particles of plaster. The material in the pan shall then be elutriated (purified by washing and straining, effecting as clean a separation of fiber from plaster as is feasible) catching the elutriated fibers on a No. 100 sieve. To avoid loss of the fine particles of fiber, it may be necessary to make the transfer from the pan to the No. 100 sieve by several stages of washing, stirring the charge, and quickly pouring upon the sieve the fiber flotations, repeating the elutriation procedure several times. The fiber collected on the No. 100 sieve shall then be examined, and the elutriation shall be repeated if it seems desirable.

(*b*) The sieves (or sieve, as the case may be) and the residue contained therein shall then be dried overnight in an oven maintained at a temperature of 45 C. The sieves, or sieve, shall then be carefully inverted over a piece of white paper, and the residual material transferred to the paper by brushing the bottom of the inverted sieve. The transferred material shall then be examined visually, noting whether the separation of fibers from plaster has been complete. The material shall then be transferred to a weighed platinum crucible and dried to constant weight at a temperature of 45 C. If the previous visual examination of the charge on the white paper showed that the fiber was practically free of particles of plaster, the weight of the fiber dried at 45 C., divided by 100, shall be reported as the percentage of fiber. If, on the other hand, the visual examination revealed the presence of an appreciable quantity of plaster associated with the fiber, the contents of the crucible shall be ignited carefully to constant weight. The loss on ignition, divided by 100, shall, in this case, be reported as the percentage of fiber.

COMPRESSIVE STRENGTH OF GYPSUM PARTITION TILE OR BLOCK

Test Specimens

39. Not less than ten full-size tile or block specimens shall be tested. The specimens shall be dried at a temperature of not less than 70 F. (21.1 C.) nor more than 100 F. (37.8 C.) in an atmosphere having a relative humidity of not more than 50 per cent. The specimens shall be weighed at 1-day intervals until constant weight is attained. At the option of the manufacturer or purchaser, strength tests may be conducted on specimens that are dried at room temperature. However, in cases of controversy all test specimens shall be dried to constant weight as herein prescribed.

Procedure

40. (*a*) The specimen shall be tested in the position in which the tile or block is designed to be used, and shall be bedded on and capped with a felt pad not less than $\frac{1}{8}$ nor more than $\frac{1}{4}$ in. in thickness. At the option of the manufacturer or purchaser, or in cases of controversy, the specimens may be suitably capped with calcined gypsum mortar, or the bearing surfaces of the tile may be planed or rubbed smooth and true. When calcined gypsum is used for capping, the test may be conducted after the capping has set and the specimen has been dried to constant weight in accordance with Section 39.

(*b*) The loading head shall completely cover the bearing area of the specimen, and the applied load shall be transmitted through a spherical bearing block of proper design. The speed of the moving head of the testing machine shall be not more than 0.05 in. per min.

FLEXURAL STRENGTH OF GYPSUM BOARDS

Test Specimens

41. Test specimens shall be taken from not less than ten gypsum boards. The test specimens shall be 12 in. in width and a proximately 16 in. in length. The specimens shall be weighed to within 0.5 g. and then stored at a temperature of 60 to 85 F. (15.6 to 29.4 C.) in an atmosphere having a relative humidity of 25 to 50 per cent. The specimens shall be weighed once a day until the weight has become constant to within 0.1 per cent.

Procedure

42. The test specimen shall be centrally supported on fixed parallel bearings spaced 14 in. between centers, and the load-applying block shall be brought in contact with the upper surface of the specimen midway between the supports. All bearings and load surfaces shall be true, shall engage the full width of the test specimen, and shall be rounded to a radius of $\frac{1}{8}$ in. The test load shall be applied at a uniform rate of 60 lb. per min. with a permissible variation of plus or minus 10 per cent in the rate.

Report

43. The results of the flexural strength tests shall be reported for the load applied across the fiber of the surfacing and also parallel to the fiber of the surfacing.

Standard Definitions of

TERMS RELATING TO GYPSUM[1]

A.S.T.M. Designation: C 11 – 41

ADOPTED, 1926; REVISED, 1928, 1939, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 11; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Accelerator.—In the case of stucco, plaster, mortar, concrete, etc., a substance which will hasten the set.

Binder.—In the case of plaster and stucco, etc., a fibrous material, which will increase their cohesiveness, while they are in a plastic state.

Cement.—A material or a mixture of materials (without aggregate) which, when in a plastic state, possesses adhesive and cohesive properties, and which will harden in place.

NOTE.—The word "cement" is used without regard to the composition of the material.

Calcined Gypsum.—Gypsum partially dehydrated by means of heat, having the approximate chemical formula $CaSO_4 \cdot \frac{1}{2}H_2O$.

Crushed Gypsum.—Gypsum subjected to a primary crushing operation.

Gypsum.—Calcium sulfate, combined with two molecules of water, in crystalline form, having the approximate chemical formula $CaSO_4 \cdot 2H_2O$.

Gypsum Lath.—A sheet or slab having an incombustible core of gypsum, containing not more than 15 per cent by weight of fiber, and surfaced with paper suitable to receive gypsum plaster.

Gypsum Molding Plaster.—A material consisting essentially of calcined gypsum for use in making interior embellishments, cornices, etc.

Gypsum Pottery Plaster.—A material consisting essentially of calcined gypsum for use in making pottery molds.

Gypsum Partition Tile or Block.—A gypsum building unit in form of tile or block for use in nonbearing construction in the interior of buildings and for the protection of columns, elevator shafts, etc., against fire.

NOTE 1.—The words "tile" and "block" are synonymous and are used so as to be in accord with certain freight association nomenclature.

NOTE 2.—Gypsum cored tile, 3 or 4 in. in thickness, may be split and used for furring purposes.

Gypsum Sheathing Board.—A sheet or slab having an incombustible core of gypsum, containing not more than 15 per cent by weight of fiber, and surfaced with a water-resistive paper.

Gypsum Wall Board.—A sheet or slab having an incombustible core of gypsum, containing not more than 15 per cent by

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-11 on Gypsum.

[2] Prior to adoption as standard, these definitions were published as tentative from 1916 to 1926, being revised in 1921, 1922, 1924, and 1925.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

weight of fiber, and surfaced with paper suitable to receive decoration.

Keene's Cement.—Anhydrous calcined gypsum, the set of which is accelerated by the addition of other materials.

Lath.—A material whose primary function is that of a base or background for the reception of plaster or stucco.

Mortar.—A material used in a plastic state, which can be troweled, and becomes hard in place, to bond units of masonry structures.

NOTE.—The word "mortar" is used without regard to the composition of the material, and is defined only with reference to its use as a bonding material as contrasted with the words "stucco" and "plaster."

Plaster.—A material used in a plastic state, which can be troweled, to form a hard covering for the interior surfaces, walls, ceilings, etc., in any building or structure.

NOTE 1.—The word "plaster" is used without regard to the composition of the material, and is defined only with reference to its use and location of use as contrasted with the words "stucco" and "mortar."

NOTE 2.—This does not include decorative media ordinarily applied with a brush.

Retarder.—In the case of stucco, plaster, mortar, concrete, etc., a substance which will retard the set.

Sized Gypsum.—Crushed gypsum of prescribed size of individual particles.

Stucco.—A material used in a plastic state, which can be troweled, to form a hard covering for the exterior walls or other exterior surfaces of any building or structure.

NOTE.—The word "stucco" is used without regard to the composition of the material, and is defined only with reference to its use and location of use as contrasted with the words "plaster" and "mortar."

Wood Fiber.—A material produced by grinding or shredding wood.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A75.1-1942

Standard Specifications for

CONCRETE BUILDING BRICK[1]

A.S.T.M. Designation: C 55 - 37

ADOPTED, 1934; REVISED, 1937.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 55; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover concrete building brick manufactured from a mixture of portland cement and suitable aggregates such as sand, gravel, crushed stone, bituminous or anthracite cinders, burned clay or shale, or blast-furnace slag, and intended for use in brick masonry. Two grades[3] of brick are covered:

Grade A.—Brick intended for use where exposed to temperature below freezing in the presence of moisture.

Grade B.—Brick intended for use as back-up or interior masonry.

NOTE.—As an example, brick in exposed masonry protected by a facing of 3 in. or more of suitable masonry.

(*b*) When brick are required having strengths greater than prescribed by these specifications, the purchaser should specify the desired minimum compressive strength.

(*c*) If brick having a particular color, texture, finish, or uniformity are desired, these features should be specified separately by the purchaser.

Physical Properties

2. (*a*) The brick shall conform to the physical requirements for the grade[3] specified, as prescribed in Table I.

TABLE I.—PHYSICAL REQUIREMENTS.

Designation	Minimum Compressive Strength (brick flatwise), psi., average gross area		Minimum Modulus of Rupture (brick flatwise) psi., average gross area	
	Average of 5 Brick	Individual	Average of 5 Brick	Individual
Grade A.....	2500	2000	450	300
Grade B.....	1250	1000	300	200

(*b*) Unless otherwise specified by the purchaser, brick of grade A shall be accepted in lieu of grade B.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1924 to 1934, being revised in 1928 and 1933. Editorially revised and rearranged in 1939.

[3] Attention is called to the fact that when these specifications were editorially revised and rearranged in 1939 the designations of grades A and B were interchanged. The present grade A was formerly designated grade B, and grade B was designated grade A in the standard as published in the 1937 Supplement to Book of A.S.T.M. Standards, Part II.

Size

3. Brick shall conform to the following dimensions:

	Dimension, in.	Permissible Variation, in.
Depth.....	$2\frac{1}{4}$	$\frac{1}{16}$
Width.....	$3\frac{3}{4}$	$\frac{1}{8}$
Length.....	8	$\frac{1}{4}$

Visual Inspection

4. Brick shall pass a visual inspection for freedom from cracks and irregularity.

Sampling and Testing

5. (*a*) For purpose of tests, brick that are representative of the commercial product shall be selected by a competent person appointed by the purchaser, the place or places of selection to be designated when the purchase order is placed. The manufacturer or the seller shall furnish specimens for tests without charge.

(*b*) The brick shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Brick (A.S.T.M. Designation: C 67) of the American Society for Testing Materials.[4]

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: M 114-41

Standard Specifications for

BUILDING BRICK (MADE FROM CLAY OR SHALE)[1]

A.S.T.M. Designation: C 62 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 62; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover brick made from clay or shale and burned, and intended for use in brick masonry (see Explanatory Note). Three grades of brick are covered:

Grade SW.—Brick intended for use where a high degree of resistance to frost action is desired and the exposure is such that the brick may be frozen when permeated with water.

NOTE.—As a typical example, brick used for foundation courses and retaining walls in portions of the United States subject to frost action should conform to this grade. Compliance with this grade is also recommended where a high and uniform degree of resistance to disintegration by weathering is desired.

Grade MW.—Brick intended for use where exposed to temperatures below freezing but unlikely to be permeated with water or where a moderate and somewhat nonuniform degree of resistance to frost action is permissible.

NOTE.—As a typical example, brick used in the face of a wall above ground should conform to this grade. Such exposure is not likely to result in permeation of a brick by water if horizontal surfaces are protected. (See discussion of grade MW in Explanatory Note.)

Grade NW.—Brick intended for use as back-up or interior masonry, or if exposed, for use where no frost action occurs; or if frost action occurs where the average annual precipitation is less than 20 in.

Physical Properties

2. (*a*) *Durability.*—The brick shall conform to the physical requirements for the grade specified, as prescribed in Table I.

(*b*) Unless otherwise specified by the purchaser, brick of grades *SW* and *MW* shall be accepted in lieu of grade *NW*, and grade *SW* in lieu of grade *MW*.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1927 to 1929, being revised in 1928. They were adopted in 1929, published as standard from 1929 to 1938, being revised in 1930. A revision in the form of separate tentative specifications was issued from 1935 to 1944, being revised in 1936, 1937, 1939, 1940, and 1941.

Prior to their publication as tentative in 1927, these specifications comprised a portion of the Standard Specifications for Building Brick (C 21 - 20) which were published as tentative from 1919 to 1920, being revised in 1920, adopted in 1920, but withdrawn and replaced by C 62 - 27 T in 1927.

(*c*) If the average compressive strength is greater than 8000 psi. *or* the average water absorption is less than 8.0 per cent after 24-hr. submersion in cold water, the requirement for saturation coefficient shall be waived.

(*d*) *Freezing and Thawing.*—The requirements specified in Paragraph (*a*) for water absorption (5-hr. boiling) and saturation coefficient shall be waived provided a sample of five brick, meeting all other requirements, complies with the following requirements when subjected to 50 cycles of the freezing-and-thawing test:[a]

Grade SW..... No breakage and not greater than 1.0 per cent loss in dry weight of any individual brick.

Grade MW..... No breakage and not greater than 3.0 per cent loss in dry weight of any individual brick.

[a] Brick are not required to conform to the provisions of Section 2 (*d*), and these do not apply unless the sample fails to conform to the requirements for absorption and saturation coefficient prescribed in Table I as well as the strength and absorption requirements in Section 2 (*c*).

A particular lot or shipment shall be given the same grading as a previously tested lot, without repeating the freezing-and-thawing test, provided the brick are made by the same manufacturer from similar raw materials and by the same method of forming; and provided also that a sample of five brick selected from the particular lot has an average and individual minimum strength not less than a previously graded sample, and has average and individual maximum water absorption and saturation coefficient not greater than those of the previously tested sample graded according to the freezing-and-thawing test.

(*e*) *Strength.*—When brick are required having strengths greater than prescribed by these specifications, the purchaser should specify the desired minimum compressive strength.

NOTE.—A recommended classification is that given in "Recommended Minimum Requirements for Masonry Wall Construction," Report of Building Code Committee of U. S. Department of Commerce (1931). In this report the following four grades of brick according to compressive strength, tested flatwise, are recognized: 1500 to 2500 psi, 2500 to 4500 psi, 4500 to 8000 psi, and over 8000 psi.

TABLE I.—PHYSICAL REQUIREMENTS.

Designation	Minimum Compressive Strength (brick flatwise), psi., gross area		Maximum Water Absorption by 5-hr. Boiling, per cent		Maximum Saturation Coefficient[a]	
	Average of 5 Brick	Individual	Average of 5 Brick	Individual	Average of 5 Brick	Individual
Grade SW.....	3000	2500	17.0	20.0	0.78	0.80
Grade MW.....	2500	2200	22.0	25.0	0.88	0.90
Grade NW.....	1500	1250	no limit	no limit	no limit	no limit

[a] The saturation coefficient is the ratio of absorption by 24-hr. submersion in cold water to that after 5-hr. submersion in boiling water.

(*f*) *Appearance.*—If brick having a particular color, texture, finish, uniformity or freedom from cracks, warpage, exposed stones, pebbles, or particles of lime are desired, these features should be specified separately by the purchaser, or a sample or samples should be selected to serve as a standard of comparison to which the brick furnished shall conform.

NOTE.—Minor identations or surface cracks, incidental to the usual method of manufacture or the small chipping resulting from the customary methods of handling in shipment and delivery should not be deemed grounds for rejection unless particularly specified to the contrary.

Size and Coring

3. (*a*) *Size.*—The size of brick shall be as specified by the purchaser within permissible variations of plus or minus $\frac{1}{16}$ in. in depth, plus or minus $\frac{1}{8}$ in. in width, and plus or minus $\frac{1}{4}$ in. in length.

NOTE.—The standard size of brick is $2\frac{1}{4}$ by $3\frac{3}{4}$ by 8 in. At present, brick of this size are not produced in some parts of the United States and purchasers should ascertain the size or sizes available.

(*b*) *Coring.*—The net cross-sectional area of brick shall be at least 75 per cent of the gross cross-sectional area (including holes), when measured in a plane parallel with the bearing surface of the brick.

Visual Inspection

4. (*a*) The brick, as delivered to the site, shall, by visual inspection, conform to the requirements specified by the purchaser or to the sample or samples approved as the standard of comparison and to the samples passing the tests for physical requirements.

(*b*) Unless otherwise agreed upon by the purchaser and the seller, a delivery of brick shall contain not more than 5 per cent of broken brick (bats).

Sampling and Testing

5. (*a*) For purpose of tests, brick that are representative of the commercial product shall be selected by a competent person appointed by the purchaser, the place or places of selection to be designated when the purchase order is placed. The manufacturer or the seller shall furnish specimens for tests without charge.

(*b*) The brick shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Brick (A.S.T.M. Designation: C 67) of the American Society for Testing Materials.[3]

Cost of Tests

6. Unless otherwise specified in the purchase order, the cost of tests shall be borne as follows:

(*a*) If the results of the tests show that the brick do not conform to the requirements of these specifications, the costs shall be borne by the seller.

(*b*) If the results of the tests show that the brick do conform to the requirements of these specifications, the costs shall be borne by the purchaser.

EXPLANATORY NOTE

Extensive tests of brick masonry as well as observations of masonry structures in the field indicate that the important properties of brick which affect the appearance and performance of masonry in buildings are size, color and texture, compressive strength, durability, and suction when laid. Data indicate that a low rate of suction (20 g. per min. or less) is desirable both from the standpoint of bond and watertightness, and since the suction rate of brick that normally have high rates of suction can be reduced to any predetermined value by wetting before laying, this property should not be included in specifications for brick, but may properly be made a part of specifications governing workmanship.

Other properties of brick such as density, soluble salt content, and homogeneity probably also affect the performance of the masonry. Data are not available, however, from which measures of those properties or their effects upon the masonry may be determined, and consequently there are no bases for controlling these factors through a specification. Their effects may be best judged by the record of performance of similar products.

These specifications provide a basis for specifying the following properties of brick, which, as indicated above, appear to be important:

Size.—The dimensions of the standard size brick, together with permissible variations, are given in Section 3 of these specifications. Many brick and solid units are produced in other

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

sizes, however, and when sizes other than standard are acceptable or required, such sizes, together with permissible variations in dimensions, should be specified by the purchaser.

Color and Texture.—Brick are manufactured in a wide variety of colors and textures, neither of which have been standardized. Both color and texture are difficult to describe and a complete list of the products now produced, if obtainable, would be too voluminous to include in a specification. These properties are covered in Section 2 (*f*) of these specifications, which provides that color, texture, finish, and uniformity should be specified by the purchaser. The common practice is to refer to an approved sample.

Compressive Strength.—The compressive strength of brick produced in the United States ranges from 1000 psi. or less (under-burned) to over 20,000 psi. Data are available from which the compressive strength of masonry walls may be predicted with reasonable accuracy if the strength of the brick and the strength of the mortar are known. In the great majority of cases, however, the compressive stresses in masonry walls are relatively low (under 100 psi.) and for such structures minimum compressive strengths of brick of from 1500 to 2500 psi. are ample. These minimum values are included in Section 2 (*a*) of these specifications; when brick having higher strengths are desired, the required strength should be specified by the purchaser as provided in Section 2 (*e*). Strength gradings as set up by the Building Code Committee of the U. S. Department of Commerce are included in this section.

Durability.—Experience has indicated that any well-burned brick will resist the action of freezing and thawing over a long period of time and, from a structural standpoint, may be considered durable. There is a reasonably close correlation between the performance of brick in the freezing-and-thawing test and under the agents of weathering in masonry structures, and at the present time this test appears to be the best measure of the durability of brick. Freezing-and-thawing tests consist of subjecting the brick to alternate cycles (50 or more) of freezing and thawing in the presence of moisture, which requires a period of 10 weeks or more to complete. This makes it impractical as an acceptance test, and for this reason extensive research has been carried on to correlate other physical properties of brick with their resistance to the freezing-and-thawing test.

For brick produced of the same raw material and by the same method of manufacture, either compressive strength or total absorption may be taken as fairly accurate measures of the resistance of such brick to the freezing-and-thawing test; however, limits on these properties that apply to one product do not apply to products produced from different raw materials or by different manufacturing processes, and consequently they alone cannot be used as measures of durability in general specifications. A third property known as "saturation coefficient", when used in conjunction with compressive strength and total absorption by 5-hr. boiling, has been found to provide a means of predicting the resistance of most types of brick to freezing-and-thawing tests with greater accuracy than any other method developed to date.

The saturation coefficient is the ratio of the absorption by 24-hr. submersion in cold water to the absorption after 5-hr. submersion in boiling water and is defined generally as the ratio of easily filled to total fillable pore space. The theory of the saturation coefficient is that if only a part of the total pore space is occupied by water there is room for expansion on freezing into the remaining pore space without disruption of the material. The data indicate that if the easily fillable pore space, that is, the maximum water that might be absorbed by a brick in a wall subjected to excessive moisture does not exceed 80 per cent of the total pore space, the remaining space will relieve the pressure due to expansion on freezing.

While this theory seems to be applicable to many types of brick, it has been found that it does not apply to certain types of de-aired products. Strength and absorption are, therefore, used as measures of durability for these products and their acceptance should be based upon Section 2 (*c*) of these specifications.

The relationship also does not appear to hold for some brick of very high absorption (exceeding the maximum permitted in these specifications) and the acceptance of these products should be in accordance with Section 2 (*d*) which provides for special measures based upon actual freezing-and-thawing tests of the particular product.

In classifying brick according to their resistance to the freezing-and-thawing test, they fell into three general groups as indicated in Table I of these Specifications:

Grade SW which are not affected by the test, and whose appearance and structure remain unchanged.

Grade MW which are for the most part well-burned brick but may include some brick which change materially in appearance when exposed to weathering.

The limits for absorption and saturation coefficient in the grade MW classification have been set to include the average production of

those districts which do not grade or classify their kiln output beyond elimination of extremely underburned (salmon) brick. These "kiln run" shipments frequently include a small percentage of brick which, on exposure to weathering, will lose their surfaces by powdering, flaking, or spalling, and thus produce an unsightly appearance of the exposed masonry surface. Data indicate that brick cannot be classified into intermediate durability. Actually grade MW includes a mixture of durable and nondurable brick. It should be emphasized, however, that disintegration is not necessarily a characteristic of brick in this grade. Certain plants may supply brick under the grading, all of which remain unchanged in appearance even under severe conditions of exposure. The purchaser is advised to examine the field behavior of brick in districts where production classifies as grade MW and reach his own decision as to whether the appearance and condition of masonry at the age of 10 or 20 years is satisfactory.

Grade NW which includes underburned brick that will disintegrate when subjected to freezing and thawing. Such brick should not be used in structures that will be subjected to severe weathering.

In using these specifications the purchaser is urged to consider both the requirements of the structure and the physical properties of the brick available. To a degree at least, brick are a natural product, since such properties as color, compressive strength, and absorption are more or less inherent in the raw material and frequently can be changed only within narrow limits by different methods of manufacture. While the committee believes that the specifications as they now stand provide the best means available of specifying the desirable properties of brick, it recognizes that the specifications are not perfect and that due to the wide variation in raw materials and methods of manufacture, it is probable that some brick which do not conform to the requirements of grade SW still have satisfactory durability. It may also be true that some products which meet these requirements, particularly of grade MW, do not have satisfactory resistance to weathering. For this reason and because of the lack of data on some properties that may have an important bearing upon the performance of masonry, the purchaser should be guided to a degree by the record of performance of any particular product.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A78.1-1942

Standard Specifications for
SAND-LIME BUILDING BRICK[1]

A.S.T.M. Designation: C 73 – 39

ADOPTED, 1939.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 73; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover brick made from sand and lime and intended for use in brick masonry. Three grades of brick are covered:

Grade SW.—Brick intended for use where exposed to temperature below freezing in the presence of moisture.

NOTE.—As a typical example, brick used for foundation courses and parapets in the northeastern quarter of the United States should conform to grade SW.

Grade MW.—Brick intended for use where exposed to temperature below freezing but unlikely to be saturated with water.

NOTE.—As a typical example, brick exposed in the face of the wall other than parapet or foundations, or brick intended for structures located in regions of the United States characterized by less severe frost action or by drier climate than is found in the northeastern quarter of the United States, should conform to grade MW.

Grade NW.—Brick intended for use as back-up or interior masonry or if exposed, for use where no frost action occurs; or if frost action occurs where the average annual precipitation is less than 15 in.

TABLE I.—PHYSICAL REQUIREMENTS.

Designation	Minimum Compressive Strength (brick flatwise), psi., average gross area		Minimum Modulus of Rupture (brick flatwise), psi., average gross area	
	Average of 5 Brick	Individual	Average of 5 Brick	Individual
Grade SW.....	4500	3500	600	400
Grade MW.....	2500	2000	450	300
Grade NW.....	1500	1500	300	200

(*b*) When brick are required having strengths greater than prescribed by these specifications the purchaser should specify the desired minimum compressive strength.

(*c*) If brick having a particular color, texture, finish, or uniformity are desired,

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1928 to 1930. They were adopted in 1930, published as standard from 1930 to 1938, being revised in 1937, but withdrawn and republished as tentative from 1938 to 1939.

these features should be specified separately by the purchaser.

Physical Properties

2. (*a*) The brick shall conform to the physical requirements for the grade specified, as prescribed in Table I.

(*b*) Unless otherwise specified by the purchaser, brick of grades SW and MW shall be accepted in lieu of grade NW and grade SW in lieu of grade MW.

Size

3. Brick shall conform to the following dimensions:

	Dimension, in.	Permissible Variation, plus or minus, in.
Depth	$2\frac{1}{4}$	$\frac{1}{8}$
Width	$3\frac{3}{4}$	$\frac{1}{8}$
Length	8	$\frac{1}{4}$

Visual Inspection

4. Brick shall pass a visual inspection for soundness, compact structure, reasonably uniform shape, and freedom from the following: cracks, warpage, large pebbles, balls of clay, or particles of lime that would affect the serviceability or strength of the brick.

Sampling and Testing

5. (*a*) For purpose of tests, brick that are representative of the commercial product shall be selected by a competent person appointed by the purchaser, the place or places of selection to be designated when the purchase order is placed. The manufacturer or the seller shall furnish specimens for tests without charge.

(*b*) The brick shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Brick (A.S.T.M. Designation: C 67) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

PAVING BRICK[1]

A.S.T.M. Designation: C 7 - 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 7; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover vitrified clay brick for use in the construction of pavements.

Manufacture

2. Paving brick shall be manufactured from fire clay, semi-fire clay, or shale, or combinations thereof. The manufacturing process shall be such that the brick are thoroughly annealed, tough, durable, and evenly burned so that, when broken, they show a uniformly dense structure free from lime, air pockets and marked laminations. The name of the brick or the manufacturer shall be impressed on the side or end of each brick in recessed letters.

Lugs

3. (*a*) *Side Lugs.*—The brick shall be provided on one side with not less than two lugs, which shall be $\frac{3}{16}$ in. in height with a permissible variation of plus or minus $\frac{1}{16}$ in. The area of the projections or lugs measured at the base of the lug shall not exceed in total area 3 sq. in. No lug shall be continuous from top to bottom of the brick, but shall be of a type that allows free horizontal flow of the filler.

(*b*) *End Lugs.*—Vertical fiber brick shall be provided with not less than two noncontinuous lugs or portions of lugs on each end of each brick. Lugs shall be nonmeshing and shall have a total base area of not more than $2\frac{1}{2}$ sq. in. and shall be manufactured so there may be free horizontal flow of the filler. The lugs shall project from the ends so as to insure a joint opening of $\frac{3}{16}$ in. with a permissible variation of plus or minus $\frac{1}{16}$ in.

Types and Sizes

4. (*a*) Paving brick shall conform to the following types and nominal sizes. The dimensions of the brick shall be construed as applying to the body of the brick only, exclusive of lugs.

	Depth, in.	Width, in.	Length, in.
Repressed lug brick	4	$3\frac{1}{2}$	$8\frac{1}{2}$
Vertical fiber lug brick	$2\frac{1}{2}$	4	$8\frac{1}{2}$
	3	4	$8\frac{1}{2}$
	$3\frac{1}{2}$	4	$8\frac{1}{2}$
Wire-cut lug brick	4	$3\frac{1}{2}$	$8\frac{1}{2}$

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1913 to 1915, being revised in 1914. They were adopted in 1915, published as standard from 1915 to 1937, being revised in 1923 and 1930, but withdrawn, revised, and republished as tentative from 1937 to 1942, being revised in 1938 and 1940.

NOTE.—These sizes and varieties correspond to those described in Simplified Practice Recommendation R 1-40[3] of the U. S. Department of Commerce, and are subject to change from year to year.

(*b*) The edges of repressed brick shall be rounded to a radius of not more than $\frac{3}{16}$ in.

Permissible Variations in Size

5. For any lot of paving brick furnished under these specifications, the individual brick shall not vary from the nominal size requirements specified in Section 4 (*a*) by more than plus or minus $\frac{1}{8}$ in. in either transverse dimension, exclusive of kiln marks, or by more than plus or minus $\frac{1}{4}$ in. in length.

Loss in Rattler Test

6. (*a*) The percentage of loss in the rattler test of the respective sizes of paving brick specified shall not exceed the following limits:

Size of Brick, Transverse Dimensions, in.	Length, in.	Maximum Loss in Rattler Test, per cent
2½ by 4	8½	26
3 by 4	8½	24
3½ by 4	8½	22

(*b*) The total number of pieces weighing 1 lb. or more remaining after the completion of the rattler test shall not exceed 12.

Visual Inspection

7. Paving brick shall be subject to visual inspection prior to shipment, after delivery, and during laying for the purpose of culling out and rejecting individual imperfect brick. Subject to the exceptions specified in Paragraph (*b*), individual brick may be culled and rejected for the following causes:

(*a*) *Variation in Size.*—Brick which vary from the nominal size specified in Section 4 (*a*) by more than plus or minus $\frac{1}{8}$ in. in either transverse dimension, exclusive of kiln marks, or by more than plus or minus $\frac{1}{4}$ in. in length.

(*b*) *Broken or Chipped Brick.*—Brick which are chipped or broken so that neither wearing surface remains substantially intact, or so that the lower, or bearing surface is reduced in area more than 15 per cent, or are weakened structurally. However, brick so rejected but otherwise acceptable may be used for part-brick for beginning courses and for batting provided the portion so used conforms to all of the requirements for visual inspection.

(*c*) *Cracked Brick.*—Brick which are cracked to such a degree, either from shocks received in shipping and handling or from defective manufacture, as to produce defects described in Paragraph (*b*), unless such cracks are plainly superficial, and insufficient to weaken the brick under the conditions of use.

(*d*) *Warped or Kiln-Marked Brick.*—Brick which are kiln-marked more than $\frac{3}{16}$ in. or which are misshapen, bent, or twisted so that they will not form a proper surface, or align with other brick in conformance with the specifications for laying brick in the pavement. Vertical fiber brick shall have no kiln-marks in the wire cut surface.

(*e*) *Under-Burned Brick.*—Brick which are obviously too soft and too poorly vitrified to endure traffic wear. If disagreement on this requirement arises between the purchaser and the seller it shall be the right of the purchaser to make one or more rattler tests of the brick he wishes to exclude, and if in any or all tests the brick fail to conform to the requirements of these specifications, then all brick having the same objectionable appearance may be excluded.

Basis of Acceptance

8. Acceptance of any lot of paving brick shall be based on the results of

[3] Reaffirmed without change June 29, 1943. Copies are available at 5 cents each from the Superintendent of Documents, Government Printing Office, Washington, D. C.

tests on samples representing that lot, subject only to rejection at any time of individually imperfect or unsatisfactory brick, in accordance with the requirements under Section 6.

Retesting

9. (*a*) If the percentage of loss in the rattler test on any sample exceeds by not more than 2 per cent the maximum permissible rattler loss specified in Section 6 (*a*) for the size specified, or if the number of pieces weighing 1 lb. or more remaining after the completion of the rattler test exceeds 12 as specified in Section 6 (*b*), two additional tests shall be made. Each of these additional tests shall comply with the requirements of both Section 6 (*a*) and (*b*) and, in addition, the average rattler loss for the three tests shall not exceed the maximum permissible loss specified in Section 6 (*a*).

(*b*) Where a lot of paving brick is rejected for failure to meet the test requirements prescribed in these specifications, the purchaser may, at his option, permit the seller to regrade the rejected brick and again offer the brick for test and acceptance. The regraded brick shall be resampled and tested and if they again fail, the purchaser may definitely and finally reject the lot represented by the test.

Payment for Cost of Testing

10. Unless otherwise agreed, the seller shall furnish at the place of manufacture, without charge to the purchaser, the use of an approved rattler in efficient operating condition, conforming to the requirements specified in Section 12. Payment of the cost of testing shall be made by the purchaser, except that the cost of testing additional samples in accordance with Section 9, made necessary by the failure of any lot or lots, or of testing supplemental samples to determine the acceptability of a portion of any lot or lots, shall be paid by the seller; provided, however, that if the supplemental tests show the brick under examination to be acceptable, then the cost of such tests shall be paid by the purchaser.

RATTLER TEST

Sampling

11. (*a*) *Selection of Sample.*—The sample for the rattler test shall consist of ten whole undamaged brick which conform individually to the visual inspection requirements specified in Section 7. Samples shall preferably be selected at the place of manufacture and tested prior to shipment. However, in special cases where less than 100,000 brick are involved, samples, when required, may be selected subsequent to delivery at the destination.

(*b*) *Number of Samples.*—In general, one sample shall be selected for each 15,000 brick or fraction thereof; provided, however, that when the sampling is done at the place of manufacture prior to shipment and the total number of brick involved is more than 100,000 brick, the number of brick for which one sample is considered representative may be increased at the option of the purchaser to not more than 50,000 brick.

Apparatus

12. The machine[4] used in the rattler test shall be of good mechanical construction, self-contained, and shall conform to the following details as regards the material and dimensions. It shall consist of a barrel, frame, and driving mechanism as described in Sections 13 to 15.

[4] A detailed illustration of a rattler showing the construction of a machine which will meet the requirements specified is available from the Headquarters of the American Society for Testing Materials, 260 S. Broad St., Philadelphia 2, Pa. This illustration was published previously as Plate I of the 1936 Book of A.S.T.M. Standards, Part II, p. 128.

Barrel

13. The barrel of the machine shall consist of the heads, headliners, staves, and staveliners comforming to the following requirements:

(*a*) *Heads.*—The heads may be cast in one piece with the trunnions which shall be $2\frac{7}{16}$ in. in diameter and shall have a bearing 6 in. in length; or they may be cast with heavy hubs which shall be bored out for $2\frac{7}{16}$-in. shafts and shall be key-seated for two keys, each $\frac{1}{2}$ by $\frac{3}{8}$ in. and spaced 90 deg. apart. The shaft shall be a snug fit and when keyed shall be entirely free from lost motion. The distance from the end of the shaft or trunnion to the inside face of the head shall be $15\frac{3}{8}$ in. for the head of the driving end of the rattler and $11\frac{3}{8}$ in. for the other head, and the distance from the face of the hubs to the inside face of the heads shall be $5\frac{1}{8}$ in.

The heads shall not be less than $\frac{3}{4}$ nor more than $\frac{7}{8}$ in. in thickness. In outline, each head shall be a regular 14-sided polygon inscribed in a circle $28\frac{5}{8}$ in. in diameter. Each head shall be provided with flanges not less than $\frac{3}{4}$ in. in thickness, and extending outward $2\frac{1}{2}$ in. from the inside face of the head to afford a means of fastening the staves. The surface of the flanges of the head shall be smooth and give a true and uniform bearing for the staves. To secure the desired true and uniform bearing, the surfaces of the flanges of the head shall be either ground or machined. The flanges shall be slotted on the outer edge, so as to provide for two $\frac{3}{4}$-in. bolts at each end of each stave, the slots to be $1\frac{3}{16}$ in. in width and $2\frac{3}{4}$ in. center to center. Each slot shall be provided with a recess for the bolt head, which shall act to prevent the turning of the same. Between each two slots there shall be a brace $\frac{3}{8}$ in. in thickness extending not less than 2 in. down the outward side of the head.

(*b*) *Headliners.*—There shall be for each head a cast-iron headliner, 1 in. in thickness and conforming to the outline of the head, but inscribed in a circle $28\frac{1}{8}$ in. in diameter. This headliner shall be fastened to the head by seven $\frac{5}{8}$-in. cap screws, through the head from the outside. Whenever these headliners become worn down $\frac{1}{2}$ in. below their initial surface level, at any point of their surface, they shall be replaced with new ones. The metal of these headliners shall be hard machinery iron and should contain not less than 1 per cent of combined carbon.

(*c*) *Staves.*—The staves shall be made of 6-in. medium-carbon steel structural channels $27\frac{1}{4}$ in. in length and weighing 15.5 lb. per lineal foot. The staves shall have two holes $\frac{13}{16}$ in. in diameter drilled in each end, the center line of the holes being 1 in. from the end and $1\frac{3}{8}$ in. either way from the longitudinal center line. The spaces between the staves shall be as uniform as practicable, but shall not exceed $\frac{6}{16}$ in.

(*d*) *Staveliners.*—The interior or flat side of each stave shall be protected by a liner $\frac{3}{8}$ in. in thickness by $5\frac{1}{2}$ in. in width by $19\frac{3}{4}$ in. in length. The liner shall consist of medium-carbon steel plate, and shall be riveted to the channel by three $\frac{1}{2}$-in. rivets, one of which shall be on the center line both ways and the other two on the longitudinal center line and spaced 7 in. from the center each way. The rivet holes shall be countersunk on the face of the liner and the rivets shall be driven hot and chipped off flush with the surface of the liners. These liners shall be inspected from time to time, and if found loose shall be at once re-riveted.

(*e*) *Relining.*—No stave shall be used for more than 70 consecutive tests without renewing its lining. Two of the 14 staves shall be removed and relined at a time in such a way that of each

pair one falls upon one side of the barrel and the other upon the opposite side, and also so that the staves changed shall be consecutive but not contiguous; for example, 1 and 8, 3 and 10, 5 and 12, 7 and 14, 2 and 9, 4 and 11, 6 and 13, etc., to the end that the interior of the barrel at all times shall present the same relative conditions of repair. The changes in the staves should be made at the time when the shot charges are being corrected, and the record must show the number of charges run since the last pair of new lined staves was placed in position.

(*f*) *Construction.*—The staves when bolted to the heads shall form a barrel 20 in. in length, inside measurement, between headliners. The liners of the staves shall be so placed as to drop between the headliners. The staves shall be bolted tightly to the heads by four $\frac{3}{4}$-in. bolts and each bolt shall be provided with a locknut and shall be inspected at not less frequent intervals than every fifth test and all nuts kept tight. A record shall be made after each inspection showing in what condition the bolts were found.

Barrel Frame

14. The barrel shall be mounted on a cast-iron frame of sufficient strength and rigidity to support it without undue vibration. It shall rest on a rigid foundation with or without the interposition of wooden plates, and shall be fastened thereto by bolts at not less than four points.

Driving Mechanism

15. The barrel shall be driven by gearing whose ratio of driver to driven is not less than one to four. The counter shaft upon which the driving pinion is mounted shall not be less than $1\frac{15}{16}$ in. in diameter, with bearing not less than 6 in. in length. If a belt drive is used, the pulley shall be not less than 18 in. in diameter and $6\frac{1}{2}$ in. in face. A belt at least 6 in. in width, properly adjusted to avoid unnecessary slipping, should be used.

Preliminary Operation

16. When a new rattler in which a complete set of new staves is furnished is first put into operation, it shall be charged with 400 lb. of shot of the same sizes and in the same proportion as provided in Section 17, and shall then be run for 18,000 revolutions at the rate of speed specified in Section 21 (*a*). The shot shall then be removed and a standard shot charge inserted, after which the rattler may be charged with brick for a test.

Abrasive Charge

17. The abrasive charge shall consist of cast-iron spheres of two sizes:

(*a*) *Large Spheres.*—When new, the larger spheres shall be 3.75 in. in diameter and shall weigh approximately 7.5 lb. (3.40 kg.) each. Ten spheres of this size shall be used. These shall be weighed separately after each ten tests, and if the weight of any large sphere falls to 7 lb. (3.175 kg.) it shall be discarded and a new one substituted; provided, however, that all of the large spheres shall not be discarded and substituted by new ones at any single time, and that in so far as possible the large spheres shall compose a graduated series in various stages of wear.

(*b*) *Small Spheres.*—When new, the smaller spheres shall be 1.875 in. in diameter and shall weigh approximately 0.95 lb. (0.43 kg.) each. In general, the number of small spheres in a charge shall not fall below 245 nor exceed 260. The collective weight of the large and small spheres shall be as nearly 300 lb. as possible. No small sphere shall be retained in use after it has been worn

down so that it will pass a circular hole 1.75 in. in diameter, drilled in an iron plate ¼ in. in thickness, or weigh less than 0.75 lb. (0.34 kg.)

Further, the small spheres shall be tested by passing them over the plate mentioned or by weighing, after every ten tests, and any which pass through or fall below the specified weight shall be replaced by new spheres; provided, however, that all of the small spheres shall not be rejected and replaced by new ones at any one time, and that in so far as possible the small spheres shall compose a graduated series in various stages of wear. At any time that any sphere is found to be broken or defective it shall at once be replaced.

Chemical Composition of Abrasive Charge

18. (*a*) The cast-iron abrasive spheres shall conform to the following requirements as to chemical composition:

Combined carbon, min., per cent	2.50
Graphitic carbon, max., per cent	0.25
Manganese, max., per cent	0.50
Phosphorus, max., per cent	0.25
Sulfur, max., per cent	0.08
Silicon, max., per cent	1.00

(*b*) For each new batch of spheres used, the chemical analysis shall be furnished by the maker or be obtained by the user before introducing the spheres into the abrasive charge, and unless the analysis conforms to the requirements specified the batch of spheres shall be rejected.

Scales

19. The scales used shall be placed on a solid level foundation and shall be sufficiently sensitive to determine the initial weight of 10 brick to the nearest 0.1 lb. The scale shall be tested by a standard test weight at intervals of not more than every ten tests.

Test Specimen

20. The number of brick per test shall be ten whole brick for all weights of brick, and the brick shall be weighed to the nearest 0.1 lb. Brick shall be surface dry when tested. No brick should be selected as part of a regular test that would be rejected by any other requirements of the specifications under which the purchase is made.

Procedure

21. (*a*) The test specimen and the abrasive charge shall be placed in the rattler and the machine rotated for 1800 revolutions at a rate of not less than 29.5 nor more than 30.5 rpm. A counting machine shall be attached to the rattler for counting the revolutions. A margin not to exceed ten revolutions will be allowed for starting and stopping. Only one start and stop per test is, in general, acceptable. If from accidental causes, the rattler is stopped and started more than once during a test, and the percentage loss exceeds the maximum permissible under the specifications, the test shall be disqualified and another made.

(*b*) Any test, at the expiration of which a staveliner is found detached from the stave or seriously out of position, shall be rejected.

Percentage Loss of Weight

22. The loss shall be calculated as a percentage of the original weight of the brick composing the charge, by weighing the brick remaining in the rattler at the end of the test, deducting this weight from the original weight of the brick, dividing this difference by the original weight of the brick and multiplying by 100, as follows:

$$\text{Percentage of loss} = \frac{\text{original wt.} - \text{wt. after testing}}{\text{original wt.}} \times 100$$

In weighing the rattled brick, any piece weighing less than 1 lb. shall be rejected.

Rattler Record

23. (*a*) A complete and continuous record shall be kept of the operation of all rattlers working under the rattler test. This record shall contain the following data concerning each test made:

1. The name of the person, firm, or corporation furnishing each sample tested.
2. The name of the manufacturer of the brick represented in each sample tested.
3. The name of the street or contract which the sample represented.
4. The brands or marks upon the brick by which they were identified.
5. The number of brick furnished.
6. The date on which they were received for test.
7. The date on which they were tested.
8. The drying treatment given before testing, if any.
9. The length, width, and depth of the brick.
10. The collective weight of the ten large spherical shot used in making the test, at the time of their last standardization.
11. The number and collective weight of the small spherical shot used in making the test, at the time of their last standardization.
12. The total weight of the shot charge, after its last standardization.
13. Certificate of the operator that he examined the condition of the machine as to staves, liners, and any other parts affecting the barrel, and found them to conform to the requirements at the beginning of the test.
14. Certificate of the operator as to the number of charges tested since the last standardization of shot charge and last renewals of stave liners.
15. The time of the beginning and ending of each test and the number of revolutions made by the barrel during the test, as shown by the counting machine.
16. Certificate of the operator as to the number of stops and starts made in each test.
17. The initial collective weight of the ten brick composing the charge and their collective weight after rattling.
18. The number of broken brick and remarks upon the portions which were included in the final weighing.
19. General remarks upon the test and any irregularities occurring in its execution.
20. The certificate of the operator that the test was made in accordance with the requirements of the American Society for Testing Materials and that the record is a true record.
21. The signature of the operator or person responsible for the test.
22. The location of the laboratory where the test was made and name of the owner.
23. The serial number of the test.

(*b*) In the event of more than one copy of the record of any test being required, they may be furnished on separate sheets and marked duplicate, but the original record shall always be preserved intact and complete.

Standard Specifications for

SEWER BRICK (MADE FROM CLAY OR SHALE)[1]

A.S.T.M. Designation: C 32 - 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 32; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover brick made from clay or shale and burned, and intended for use in drainage structures for the conveyance of sewage, industrial wastes, and storm water. Three grades of brick are covered:

Grade SA.—Brick intended for use in structures requiring imperviousness and resistance to the action of sewage carrying large quantities of abrasive material at velocities exceeding 8 ft. per sec.

Grade MA.—Brick intended for use in structures requiring imperviousness and resistance to the action: (*1*) of sewage free from abrasive materials, and (*2*) of sewage carrying abrasive materials at velocities of 8 ft. per sec. or less.

Grade NA.—Brick intended for use in structures not requiring high degrees of imperviousness nor of abrasive resistance.

NOTE.—Brick of grade *NA* are suitable for use in catch basins, arches, the upper portions of manholes, and for backing.

TABLE I.—PHYSICAL REQUIREMENTS.

Designation	Minimum Compressive Strength, (brick flatwise), psi., average gross area		Maximum Water Absorption by 5-hr. Boiling, per cent	
	Average of 5 Brick	Individual	Average of 5 Brick	Individual
Grade *SA*.....	8000	5000	6	9
Grade *MA*[a].....	5000	3000	12	16
Grade *NA*[a].....	2500	2000	20	24

[a] Where resistance to frost action in the presence of moisture is required, grades *MA* and *NA* shall conform to the additional requirement that the saturation coefficient (*C/B*), that is, ratio of absorption by 24-hr. submersion in cold water to that after 5 hr. submersion in boiling water, shall not exceed 0.80.

Physical Properties

2. (*a*) The brick shall conform to the physical requirements for the grade specified, as prescribed in Table I.

(*b*) Unless otherwise specified by the purchaser, brick of grade *SA* shall be accepted in lieu of grade *MA*; also grades *SA* and *MA* shall be accepted in

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1921 to 1923. They were adopted in 1923, published as standard from 1923 to 1937, being revised in 1924, but withdrawn, revised, and republished as tentative from 1937 to 1942, being revised in 1939.

lieu of grade *NA*. Brick having absorption between 12 and 20 per cent shall be graded *MA* if the compressive strength conforms to the requirements for grade *SA*.

Size

3. (*a*) Brick shall be furnished of one or more of the following designated sizes as specified:

Size	Depth, in.	Width, in.	Length, in.
No. 1	$2\frac{1}{4}$	$3\frac{3}{4}$	8
No. 2	$2\frac{1}{2}$	4	$8\frac{1}{2}$
No. 3	3	4	$8\frac{1}{2}$
No. 4	$3\frac{1}{2}$	4	$8\frac{1}{2}$

(*b*) For any lot of sewer brick furnished under these specifications, not more than 2 per cent of the brick shall vary from the nominal size requirements specified in Paragraph (*a*) by more than plus or minus $\frac{1}{8}$ in. in either transverse dimension, or by more than plus or minus $\frac{1}{4}$ in. in length.

Visual Inspection

4. (*a*) Brick shall pass a visual inspection for freedom from the following: cracks, warpage, stones, pebbles, or particles of lime that would affect the serviceability of the brick.

(*b*) Brick shall be of rectangular cross-section with substantially straight, square corners. The ends and at least one edge shall have plain surfaces.

(*c*) When paving brick are used, lugs and grooves will be permitted on one edge and the ends. Kiln marks not exceeding $\frac{3}{16}$ in. in depth shall be permitted on the opposite edge.

NOTE.—Where cored brick are permitted by the purchaser, they shall conform to the requirements of these specifications.

Sampling and Testing

5. (*a*) For purpose of tests, brick that are representative of the commercial product shall be selected by a competent person appointed by the purchaser, the place or places of selection to be designated when the purchase order is placed. The manufacturer or the seller shall furnish specimens for tests without charge.

(*b*) Brick shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Brick (A.S.T.M. Designation: C 67) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

SEWER BRICK (MADE FROM CLAY OR SHALE)[1]

A.S.T.M. Designation: C 32 - 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 32; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover brick made from clay or shale and burned, and intended for use in drainage structures for the conveyance of sewage, industrial wastes, and storm water. Three grades of brick are covered:

Grade SA.—Brick intended for use in structures requiring imperviousness and resistance to the action of sewage carrying large quantities of abrasive material at velocities exceeding 8 ft. per sec.

Grade MA.—Brick intended for use in structures requiring imperviousness and resistance to the action: (*1*) of sewage free from abrasive materials, and (*2*) of sewage carrying abrasive materials at velocities of 8 ft. per sec. or less.

Grade NA.—Brick intended for use in structures not requiring high degrees of imperviousness nor of abrasive resistance.

NOTE.—Brick of grade *NA* are suitable for use in catch basins, arches, the upper portions of manholes, and for backing.

TABLE I.—PHYSICAL REQUIREMENTS.

Designation	Minimum Compressive Strength, (brick flatwise), psi., average gross area		Maximum Water Absorption by 5-hr. Boiling, per cent	
	Average of 5 Brick	Individual	Average of 5 Brick	Individual
Grade *SA*.....	8000	5000	6	9
Grade *MA*[a].....	5000	3000	12	16
Grade *NA*[a].....	2500	2000	20	24

[a] Where resistance to frost action in the presence of moisture is required, grades *MA* and *NA* shall conform to the additional requirement that the saturation coefficient (*C/B*), that is, ratio of absorption by 24-hr. submersion in cold water to that after 5 hr. submersion in boiling water, shall not exceed 0.80.

Physical Properties

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A82.1-1944

Standard Methods of

SAMPLING AND TESTING BRICK[1]

A.S.T.M. Designation: C 67 - 44

ADOPTED, 1931; REVISED, 1937, 1939, 1941, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 67; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the sampling and testing of brick for modulus of rupture (flexure test), compressive strength, absorption, saturation coefficient, effect of freezing and thawing, initial rate of absorption (suction), and efflorescence.

Definitions of Terms

2. The Standard Definitions of Terms Relating to Methods of Testing (A.S.T.M. Designation: E 6) of the American Society for Testing Materials[3] shall be considered as applying to the terms used in these methods.

SAMPLING

Selection of Test Specimens

3. For purpose of tests, full-size brick shall be selected by the purchaser or by his authorized representative. Specimens shall be representative of the whole lot of brick from which they are selected.

Number of Specimens

4. For the modulus of rupture, compressive strength, absorption, and freezing-and-thawing determinations, at least five brick shall be selected from each lot of 50,000 brick or fraction thereof. For lots of more than 500,000 brick, five individual brick shall be selected from each 100,000 brick or fraction thereof contained in the lot. In no case shall less than five brick be taken. Additional specimens may be taken at the discretion of the purchaser.

Identification

5. Each specimen shall be marked so that it may be identified at any time. Markings shall cover not more than 5 per cent of the superficial area of the specimen.

MODULUS OF RUPTURE (FLEXURE TEST)

Test Specimens

6. Five dry full-size brick shall be tested.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these methods were published as tentative from 1927 to 1931, being revised in 1928 and 1930.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

7. (*a*) The test specimen shall be supported flatwise on a span of 7 in. and loaded at mid-span. If the specimens have recesses (panels or depressions) they shall be placed so that such recesses are on the compression side. The load shall be applied to the upper surface of the specimen through a steel bearing plate ¼ in. in thickness and 1½ in. in width and of a length at least equal to the width of the specimen. The direction of the load shall be perpendicular to the loaded surface of the specimen.

(*b*) The supports for the test specimen shall be free to rotate in the longitudinal and transverse direction of the test specimen and shall be adjusted so that they will exert no force in these directions.

(*c*) *Speed of Testing.*—The rate of loading shall not exceed 2000 lb. per min., but this requirement may be considered as being met if the speed of the moving head of the testing machine during the application of the load is not more than 0.05 in. per min.

Calculations and Report

8. (*a*) The modulus of rupture of each specimen shall be calculated as follows:

$$\text{Modulus of rupture, psi.} = \frac{3Wl}{2bd^2}$$

where:

W = maximum load indicated by the testing machine, in pounds,
l = distance between the supports in inches (7 in.),
b = average over-all width, face to face, of the specimen, in inches, and
d = average over-all depth, face to face, of the specimen, in inches.

(*b*) The average of the modulus of rupture determinations of all the specimens tested shall be reported as the modulus of rupture of the lot of brick.

COMPRESSIVE STRENGTH

Test Specimens

9. The test specimens shall consist of half brick with approximately plane and parallel ends. A specimen may be obtained from a whole brick by any method that will produce, without shattering, a half brick. Five specimens shall be tested.

NOTE.—This permits the use of suitable half brick available after the flexure test has been made.

Capping Test Specimens

10. (*a*) If the flatwise faces of the test specimen are recessed or paneled, the depressions shall be filled with a neat portland-cement paste, which shall then be aged at least 24 hr. before the specimen is capped.

(*b*) The two opposite flatwise faces of each specimen shall be coated with shellac which shall be allowed to dry thoroughly.

(*c*) One of the dry shellacked faces of the specimen shall be bedded in a thin coat of a neat paste of calcined gypsum (plaster of Paris) that has been spread on an oiled nonabsorbent plate such as glass or a machined metal plate. This procedure shall be repeated with the other dry shellacked face. Care shall be taken that the opposite bearing surfaces so formed will be approximately parallel. The caps shall be aged at least 2 hr. before the specimens are tested.

Procedure

11. (*a*) All specimens shall be tested flatwise (that is, the load shall be applied in the direction of the thickness of the brick).

(*b*) The testing machine shall conform to the requirements of the Standard Methods of Verification of Testing Machines (A.S.T.M. Designation: E 4) of the American Society for Testing Materials.[3]

(*c*) The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to turn in any direction. The diameter of the bearing surface shall be at least 5 in. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. The bearing block surfaces intended for contact with the specimen should have a hardness not less than C60 Rockwell number (Brinell number 620). These surfaces shall not depart from plane surfaces by more than 0.001 in. When the bearing area of the spherical bearing block is not sufficient to cover the area of the specimen, a steel plate with surfaces machined to true planes within plus or minus 0.001 in., and with a thickness equal to at least one third of the distance from the edge of the spherical bearing to the most distant corner, shall be placed between the spherical bearing block and the capped specimen.

(*d*) *Speed of Testing.*—When the load on the specimen exceeds approximately one half of the maximum load, the rate of loading shall be such that the load will be read accurately. Preferably, the rate of loading should not exceed 2000 psi. per min., but this requirement may be considered as being met if the speed of the moving head of the testing machine during the application of the load is not more than 0.05 in. per min.

Calculations and Report

12. (*a*) The compressive strength of each specimen shall be calculated as follows:

$$\text{Compressive strength, psi.} = \frac{W}{A}$$

where:

W = maximum load indicated by the testing machine, in pounds, and

A = average of the gross areas of the upper and lower bearing surfaces of the specimen in square inches.

(*b*) The average compressive strength of all the specimens tested shall be reported as the compressive strength of the lot of brick.

ABSORPTION

Accuracy of Weighings

13. The scale or balance used shall have a capacity of not less than 2000 g. and shall be sensitive to 0.5 g.

24-hr. Submersion Test

Test Specimens

14. The test specimens shall consist of half brick conforming to the requirements of Section 9. Five specimens shall be tested.

Procedure

15. (*a*) *Drying.*—The test specimens shall be dried to constant weight in a ventilated oven at 110 to 115 C. (230 to 239 F.). When cool, each specimen shall be weighed.

NOTE 1.—It can be assumed that heating for 72 hr. at these temperatures will assure constant weight except for deaired brick or brick whose absorption is less than 8.0 per cent by 5-hr. submersion in boiling water as determined in accordance with Section 18 (*b*).

NOTE 2.—Storage of brick, unstacked, with separate placement, in a ventilated room for a period of 4 hr., with a current of air from an electric fan passing over them for a period of at least 2 hr., will cool the specimens to approximately room temperature. Specimens noticeably warm to the touch should not be used for the absorption test.

(*b*) *Saturation.*—The dry specimen shall be submerged, without preliminary partial immersion, in clean water (soft,

distilled, or rain water) at 15.5 to 30 C. (60 to 86 F.) for 24 hr. The specimen shall then be removed, the surface water wiped off with a damp cloth, and the specimen weighed. Weighing of any one specimen shall be completed within 5 min. after removing the specimen from the bath.

Calculations and Report

16. (*a*) The absorption of each specimen shall be calculated as follows:

$$\text{Absorption, per cent} = \frac{100(W_2 - W_1)}{W_1}$$

where:

W_1 = dry weight of the specimen, and
W_2 = saturated weight of the specimen after 24-hr. submersion in cold water.

(*b*) The average absorption of all the specimens tested shall be reported as the absorption of the lot of brick.

5-hr. Boiling Test

Test Specimens

17. The test specimens shall consist of half brick conforming to the requirements of Section 9. Five specimens shall be tested.

Procedure

18. (*a*) The specimen which has been saturated 24 hr. in the cold-water submersion bath shall be returned to the bath and subjected to a 5-hr. boiling test as described in Paragraph (*b*).

(*b*) The specimen shall be submerged in clear water (soft, distilled, or rain water) at 15.5 to 30 C. (60 to 86 F.) in such a manner that water can circulate freely on all sides of the specimen. The water shall be heated to boiling within 1 hr., boiled continuously for 5 hr., and then allowed to cool to 15.5 to 30 C. (60 to 86 F.) by natural loss of heat for not less than 16 nor more than 18 hr. The specimen shall then be removed, the surface water wiped off with a damp cloth, and the specimen weighed. Weighing of any one specimen shall be completed within 5 min. after removing the specimen from the bath.

NOTE.—If the tank is equipped with a drain so that water at 15.5 to 30 C. (60 to 86 F.) can be passed through the tank continuously and at such a rate that a complete change of water takes place in not more than 2 min., weighings can be made at the end of 1 hr.

Calculations and Report

19. (*a*) The absorption of each specimen shall be calculated as follows:

$$\text{Absorption, per cent} = \frac{100(W_3 - W_1)}{W_1}$$

where:

W_1 = dry weight of the specimen, and
W_3 = saturated weight of the specimen after 5-hr. submersion in boiling water.

(*b*) The average absorption of all the specimens tested shall be reported as the absorption of the lot of brick.

Saturation Coefficient

20. The saturation coefficient of each specimen shall be calculated as follows:

$$\text{Saturation coefficient} = \frac{W_2 - W_1}{W_3 - W_1}$$

where:

W_1 = dry weight of the specimen,
W_2 = saturated weight of the specimen after 24-hr. submersion in cold water, and
W_3 = saturated weight of the specimen after 5-hr. submersion in boiling water.

FREEZING AND THAWING

Apparatus

21. (*a*) *Compressor, Freezing Chamber, and Circulator.*—The design and capacity of the freezing apparatus shall be

such that the air of the freezing chamber shall not exceed 16 F. (− 9 C.) 1 hr. after introducing the maximum charge of brick, initially at a temperature not exceeding 90 F. (32 C.).

(*b*) *Trays and Containers.*—The brick shall be set on edge in shallow metal trays having an inside depth of $1\frac{1}{2} \pm \frac{1}{2}$ in., and of suitable strength and size so that the tray with its charge of frozen brick can be removed from the freezing chamber by one man.

(*c*) *Balance.*—The scale or balance used shall have a capacity of not less than 2000 g. and shall be sensitive to 0.5 g.

(*d*) *Drying Oven.*—The drying oven shall provide a free circulation of air through the oven and shall be capable of maintaining a temperature between 110 and 115 C. (230 to 239 F.).

(*e*) *Thawing Tank.*—A thawing tank shall be provided of such dimensions as to permit the complete submergence of the specimens in their trays. Adequate means shall be provided so that the water in the tank may be kept at a temperature of 75 ± 10 F. (24 ± 5.5 C.).

(*f*) *Drying Room.*—A room maintained at a temperature of 75 ± 15 F. (24 ± 8 C.), with a relative humidity between 30 and 70 per cent, and free from drafts shall be provided for the air-drying prescribed in alternate method B.

Test Specimens

22. The test specimens shall consist of half brick with approximately plane and parallel ends resulting from the flexure test. The specimens shall be free from shattering or unsoundness resulting from the flexure test or from the absorption tests (24-hr. submersion test and 5-hr. boiling test). Five specimens shall be tested.

Method A

Procedure

23. (*a*) The specimens that have previously been subjected to the 24-hr. submersion test and to the 5-hr. boiling test shall be dried as prescribed in Section 15 (*a*).

(*b*) When cool, the specimens shall be weighed on a scale or balance to the nearest 0.5 g.

(*c*) The test specimens shall be immediately submerged, without preliminary partial immersion, in the water of the thawing tank for 48 hr. before the start of the freezing-and-thawing test.

(*d*) The test specimens shall be stood on edge in the trays so that a space of at least $\frac{1}{2}$ in. separates the specimens. Sufficient water shall be poured into the trays so that each specimen stands in $\frac{1}{2}$-in. depth of water, and the trays and their contents shall be exposed to the temperature of the freezing chamber for 20 hr.

(*e*) The trays shall be removed from the freezing chamber after 20 hr. and shall be totally immersed with their contents in the water of the thawing tank for a time of 4 hr.

(*f*) The specimens shall be frozen by the procedure prescribed in Paragraph (*d*) and thawed by the procedure prescribed in Paragraph (*e*), three times. The test specimens shall then be dried by exposure for 24 hr. in the drying room followed by 72 hr. in the drying oven as prescribed in Paragraph (*a*). The test specimens shall be cooled, reweighed, immersed in water for 48 hr., and again subjected to three cycles of freezing and thawing in accordance with Paragraphs (*d*) and (*e*).

(*g*) Alternations of drying, weighing, and submersion in water for 48 hr. followed by 3 cycles of freezing and thawing shall be continued until a total of 51 cycles of freezing and thawing has been completed, unless the test specimen has lost more than 3 per cent of its weight, calculated on the basis of its original weight when dry, or has broken,

or has disintegrated, as judged by visual inspection, equivalent to more than 3 per cent loss before completion of 51 cycles.

Calculations and Report

24. The loss in weight after 51 cycles shall be calculated as a percentage of the original weight of the dried specimen; or the number of cycles required to cause breakage or 1 per cent and 3 per cent loss in weight shall be reported.

Method B

Procedure

25. (*a*) The initial drying of the test specimens shall be done as prescribed in Section 15 (*a*).

(*b*) The weight of the dried specimens shall be obtained as prescribed in Section 23 (*b*).

(*c*) The test specimens shall be immediately submerged, without preliminary partial immersion, in the water of the thawing tank for 4 hr. before the start of the freezing-and-thawing test.

(*d*) The test specimens shall be frozen by the procedure prescribed in Section 23 (*d*) and thawed by the procedure prescribed in Section 23 (*e*), five times. Following the 4-hr. thawing after the fifth freezing, the specimens shall be stored for 40 hr. on the floor of the drying room. They shall not be stacked or piled, and there shall be a space of at least 1 in. between any two specimens. Following this period of air-drying, the specimens shall be inspected, submerged in the water of the thawing tank for 4 hr., and again subjected to 5 cycles of freezing and thawing in accordance with Section 23 (*d*) and (*e*).

(*e*) Alternations of drying and submersion in water for 4 hr., followed by 5 cycles of freezing and thawing shall be continued until a total of 50 cycles of freezing and thawing has been completed, unless the test specimen has broken or appears to have lost more than 3 per cent of its original weight as judged by visual inspection.

(*f*) After completion of 50 cycles, or when the specimen is withdrawn from test as a result of evident disintegration, the specimen shall be dried in an oven as prescribed in Section 15 (*a*).

Calculations and Report

26. The loss in weight shall be calculated as a percentage of the original weight of the dried specimen, or the number of cycles causing breakage or withdrawal of the specimen shall be reported.

INITIAL RATE OF ABSORPTION (SUCTION)

Apparatus

27. The apparatus shall consist of the following:

(*a*) *Trays or Containers.*—Watertight trays or containers having an inside depth of not less than $\frac{1}{2}$ in. and of such length and width that an area of not less than 300 sq. in. of water surface is provided. The bottom of the tray shall provide a plane, horizontal upper surface, when suitably supported, so that an area not less than 8 in. in length by 6 in. in width will be level when tested by a spirit level.

(*b*) *Supports for Brick.*—Two noncorrodible metal supports consisting of bars between 5 and 6 in. in length, having triangular, half-round, or rectangular cross-sections such that the thickness (height) will be approximately $\frac{1}{4}$ in. The thickness of the two bars shall agree within 0.001 in. and, if the bars are rectangular in cross-section, their width shall not exceed $\frac{5}{16}$ in.

(*c*) *Means for Maintaining Constant Water Level.*—Suitable means for controlling the water level above the upper surface of the supports for the brick within plus or minus 0.01 in. (Note 1), including means for adding water to

the tray at a rate corresponding to the rate of removal by the brick undergoing test (Note 2). For use in checking the adequacy of the method of controlling the rate of flow of the added water, a reference brick or half brick shall be provided whose displacement in $\frac{1}{8}$ in. of water corresponds to the brick or half brick to be tested within plus or minus 2.5 per cent. The reference brick shall be completely submerged in water for not less than 3 hr. preceding its use as described in Section 3 (*d*).

NOTE 1.—A suitable means for obtaining this accuracy in control of the water level is provided by attaching to the end of one of the bars, two stiff metal wires which project upward and return, terminating in points one of which is $\frac{1}{8} - 0.01$ in. and the other $\frac{1}{8} + 0.01$ in. above the upper surface or edge of the bar. Such precise adjustment is obtainable by use of depth plates or a micrometer microscope. When the water level with respect to the upper surface or edge of the bar is adjusted so that the lower point "dimples" the water surface when viewed by reflected light and the upper point is not in contact with the water, the water level is within the limits specified. Any other suitable means for fixing and maintaining a constant depth of immersion may be used if equivalent accuracy is obtained. As an example of such other suitable means there may be mentioned the use of rigid supports movable with respect to the water level.

NOTE 2.—A rubber tube leading from a siphon or gravity feed and closed by a spring clip will provide a suitable manual control. The so-called "chicken feed" devices as a rule lack sensitivity and do not operate with the very small changes in water level permissible in this test.

(*d*) *Balance.*—A scale or balance having a capacity of not less than 3000 g. and sensitive to 0.5 g.

(*e*) *Drying Oven.*—A drying oven conforming to the requirements of Section 21 (*d*).

(*f*) *Constant Temperature Room.*—A room maintained at a temperature of 70 ± 2.5 F. (21 ± 1.4 C).

(*g*) *Timing Device.*—A suitable timing device, preferably a stop watch or stop clock, which shall indicate a time of 1 min. to the nearest second.

Test Specimens

28. The test specimens shall consist of whole brick or of half brick conforming to the requirements of Section 9. Five specimens shall be tested.

Procedure

29. (*a*) *Drying.*—The test specimens shall be dried in accordance with Section 15 (*a*).

(*b*) *Cooling.*—After drying, the test specimens shall be cooled in the constant temperature room (Section 27 (*f*)) by storage, unstacked, with separate placement for a period of at least 4 hr.

(*c*) *Measurement and Weighing.*—The length and width of the flatwise surface of the test specimen which will be in contact with the water shall be measured to the nearest 0.05 in. The specimen shall be weighed to the nearest 0.5 g.

(*d*) *Adjustment of Water Level.*—The tray for the absorption test shall be set up in the constant temperature room. The position of the tray shall be adjusted so that the upper surface of its bottom shall be level when tested by a spirit level and the saturated reference brick (Section 27 (*c*)) shall be set in place on top of the supports. Water shall be added until the water level is $\frac{1}{8} \pm 0.01$ in. above the top of the supports.

(*e*) *Absorption and Reweighing.* — After removal of the reference brick, the test brick shall be set in place flatwise, counting zero time as the moment of contact of the brick with the water. During the period of contact (1 min. ± 1 sec.) the water level shall be kept within the prescribed limits by adding water as required. At the end of 1 min. ± 1 sec., the brick shall be lifted from contact with the water, the surface water wiped off with a damp cloth, and the brick reweighed to the nearest 0.5

g. Wiping shall be completed within 10 sec. of removal from contact with water and weighing shall be completed within 2 min.

NOTE.—Placing of the brick in contact with the water shall be done quickly but without splashing. Setting the brick in position with a rocking motion will avoid the entrapping of air on its under surface. Brick with frogs or depressions in one flatwise surface shall be tested with the frog or depression uppermost.

Calculations and Report

30. (*a*) The difference in weight in grams between the initial and final weighings is the weight in grams of water absorbed by the brick during 1-min. contact with water. If the test specimen is a whole brick and the area of its flatwise surface (length times width) does not differ more than plus or minus 0.75 sq. in. (plus or minus 2.5 per cent) from 30 sq. in., the gain in weight in grams shall be reported as the initial rate of absorption in 1 min.

(*b*) If the test specimen is not a whole brick or the area of its flatwise surface differs more than plus or minus 0.75 sq. in. (plus or minus 2.5 per cent) from 30 sq. in., the gain in weight shall be calculated to the equivalent for 30 sq. in. as follows:

$$X = \frac{30\ W}{LB}$$

where:

X = gain in weight corrected to basis of 30 sq. in. flatwise area,
W = actual gain in weight of specimen in grams,
L = length of specimen in inches, and
B = width of specimen in inches.

The corrected gain in weight, X, shall be reported as the initial rate of absorption in 1 min.

(*c*) If the test specimen is a cored brick, the net area shall be calculated and substituted for LB in the formula given in Paragraph (*b*). The corrected gain in weight shall be reported as the initial rate of absorption in 1 min.

EFFLORESCENCE

Apparatus

31. The apparatus shall consist of the following:

(*a*) *Trays and Containers.* — Watertight shallow pans or trays made of metal or other material that will not provide soluble salts when in contact with distilled water containing leachings from brick. The pan shall be of such dimensions that it will provide not less than a 1-in. depth of water. Unless the pan provides an area such that the total volume of water is large in comparison with the amount evaporated each day, suitable apparatus shall be provided for keeping a constant level of water in the pan.

(*b*) *Drying Room.*—A drying room conforming to the requirements of Section 21 (*f*).

(*c*) *Drying Oven.*—A drying oven conforming to the requirements of Section 21 (*d*).

Test Specimens

32. (*a*) Ten dry full-size brick shall be tested.

(*b*) The ten specimens shall be sorted into five pairs, so that both specimens of each pair will have the same appearance, as nearly as possible.

Preparation of Specimens

33. The specimens shall be tested as received, except that any adhering dirt that might be mistaken for efflorescence shall be removed by brushing.

Procedure

34. (*a*) One specimen from each of the five pairs shall be set on end, partially immersed in distilled water to a depth of approximately 1 in. for 7 days in the drying room. When several specimens

are tested in the same container, the individual specimens shall be separated by a space of at least 2 in.

NOTE 1.—Testing specimens from different sources simultaneously in the same container is not recommended, because specimens with a considerable content of soluble salts may contaminate the salt-free specimens.

NOTE 2.—The pans or trays should be emptied and cleaned after each test.

(*b*) The second specimen from each of the five pairs shall be stored in the drying room without contact with water.

(*c*) At the end of 7 days, the first set of specimens shall be inspected and both sets shall then be dried in the drying oven for 3 days.

NOTE 3.—A drying period of 24 hr. is sufficient for the purpose of an efflorescence test. A 3-day period of drying prepares the specimens for the other tests (modulus of rupture, compressive strength, absorption, and initial rate of absorption) that may be specified.

Examination and Rating

35. After drying, each pair of specimens shall be examined and compared, observing the top and all four faces of each specimen. If there is no observable difference due to efflorescence, the rating shall be reported as "no efflorescence." If any difference due to efflorescence is noted, the specimens shall be viewed from a distance of 10 ft., under an illumination of not less than 50 foot-candles, by an observer with normal vision. If under these conditions no difference is noted, the rating shall be reported as "slightly effloresced." If a perceptible difference due to efflorescence is noted under these conditions, the rating shall be "effloresced." The appearance and distribution of the efflorescence shall be recorded.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A74.1-1942

Standard Specifications for

STRUCTURAL CLAY LOAD-BEARING WALL TILE[1]

A.S.T.M. Designation: C 34 - 41

ADOPTED, 1936; REVISED, 1939, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 34; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover structural clay load-bearing wall tile made from surface clay, shale, fire clay, or mixtures thereof. Two grades of tile are covered, as follows:

Grade LB X.—Suitable for general use in masonry construction and adapted for use in masonry exposed to weathering, provided they are burned to the normal maturity of the clay. They may also be considered suitable for the direct application of stucco.

Grade LB.—Suitable for general use in masonry where not exposed to frost action, or for use in exposed masonry where protected with a facing of 3 in. or more of stone, brick, terra cotta, or other masonry.

(*b*) If tile having a particular color, texture, or finish are desired, these features should be specified separately by the purchaser (see Explanatory Note 1).

Physical Properties

2. (*a*) Structural clay load-bearing wall tile shall conform to the requirements as to physical properties for the grade specified as prescribed in Table I.

TABLE I.—PHYSICAL REQUIREMENTS.

Grade	Absorption,[a] per cent			Compressive Strength (Based on Gross Area),[b] psi.			
				End-Construction Tile		Side-Construction Tile	
	Average of Five Tests	Individual Maximum	Individual Minimum	Minimum Average of Five Tests	Individual Minimum	Minimum Average of Five Tests	Individual Minimum
LB X	5 to 16	19	4	1400	1000	700	500
LB	5 to 25	28	4	1000	700	700	500

[a] The range in percentage absorption for tile delivered to any one job shall be not more than 12.

[b] Gross area of a unit shall be the total area including cells of a section perpendicular to the direction of loading. Re-entrant spaces are included in the gross area, unless these spaces are to be occupied in masonry by portions of adjacent units.

(*b*) Tile of grade LB X shall be accepted under all conditions in lieu of grade LB.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1921 to 1926, being revised in 1924 and 1926. They were adopted in 1926, revised in 1927, 1930, and 1931, but withdrawn and replaced in 1934 by C 34 - 34 T which were published as tentative from 1933 to 1936, being revised in 1934, 1935, and 1936.

(*c*) End-construction tile are tile designed to be placed in the wall with axes of the cells vertical. Side-construction tile are tile designed to be placed in the wall with the axes of the cells horizontal. Where end-construction tile are used on the side they shall conform to the requirements of side-construction tile and *vice versa*.

(*d*) Bonding tile shall be so designed as to provide recesses for header brick courses when laid up in brick-faced walls.

Number of Cells

3. (*a*) Load-bearing tile shall conform to the following requirements as to minimum number of cells[a] in the direction of wall thickness (see Explanatory Note 2 for approximate weights of tile):

Nominal Horizontal Thickness of Tile as Laid in Wall, in.	Minimum Number of Cells[a] in Direction of Wall Thickness
4	1
6	2
8	2
10	2
12	3

[a] Cells are hollow spaces enclosed within the perimeter of the exterior shells, and having a minimum dimension of not less than $\frac{1}{2}$ in. and a cross-sectional area of not less than 1 sq. in.

(*b*) In double-shell tile, the two voids between exterior and interior shells on either side of the tile shall be considered as one cell in thickness of wall when their combined width is not less than $\frac{1}{2}$ in., provided the short webs between the inner and outer shells are not greater in number or thickness than the long transverse webs holding the inner shells.

(*c*) Re-entrant spaces not less than 1 in. in depth and not less than 1 sq. in. in area, which form cells when the units are laid in the walls, shall be considered as cells in the direction of wall thickness, but not in the units.

Shell and Web Thickness

4. (*a*) The average over-all thickness of the shells, measured between the inner and extreme outer surfaces of end-construction load-bearing tile, shall be not less than $\frac{3}{4}$ in., except that in double-shell tile the combined average over-all thickness of the inner and outer shell shall be not less than $\frac{3}{4}$ in. The thickness of the webs shall be not less than $\frac{1}{2}$ in.

(*b*) The average over-all thickness of the shells, measured between the inner and extreme outer surfaces of side-construction load-bearing tile, shall be not less than $\frac{3}{8}$ in., except that in double-shell tile the combined average over-all thickness of the inner and outer shell shall be not less than $\frac{3}{4}$ in. The thickness of the webs shall be not less than $\frac{1}{2}$ in.

(*c*) The width of any cell in side-construction tile, measured in the direction of wall thickness, shall not exceed four and one half times the average over-all thickness of either the upper or lower bearing shells. If no cell in side-construction tile, measured in the direction of the wall thickness, exceeds four times the average over-all thickness of either the upper or lower bearing shells, the requirements for minimum shell and web thickness specified in Paragraph (*b*) shall be waived.

(*d*) The thickness of bonding and other types of tile manufactured for use in combination with brick or other materials may vary from the nominal thicknesses indicated in Section 3, as required by construction requirements.

Permissible Variations in Dimensions

5. No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form or size of tile.

Scoring

6. Surfaces of all tile intended for the direct application of plaster or stucco shall be scratched or scored. When

scored, each groove shall be not less than $\frac{1}{8}$ nor more than $\frac{1}{4}$ in. in depth, nor more than 1 in. in width. The area covered by the grooves shall not exceed 50 per cent of the area of the scored faces.

Marking

7. All load-bearing wall tile shall bear the word "Load-Bearing," or LB X or LB, and the name, initials, or trade mark of the manufacturer. These marks shall be indented on the exterior of the tile and shall be legible.

Visual Inspection

8. (*a*) All tile shall be reasonably free from laminations and from cracks, blisters, surface roughness, and other defects that would interfere with the proper setting of the tile or impair the strength or permanence of the construction.

(*b*) When unscored (smooth) tile are specified, the requirements, except as to scoring, shall be the same as for scored tile. If closer tolerances on dimensions and on freedom from belt marks, chips, surface discolorations, and roughness are desired, such requirements shall be clearly defined in supplementary specifications.

Rejection

9. In case the shipment fails to conform to the requirements for the grade specified, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to meet the requirements, the entire lot shall be rejected.

Expense of Tests

10. Except as specified in Section 9, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

Sampling and Testing

11. (*a*) The purchaser or his authorized representative shall be accorded proper facilities for sampling and inspection of units both at the place of manufacture and at the site of the work. At least ten days from the time of sampling should be allowed for completion of the tests.

(*b*) Tile shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Structural Clay Tile (A.S.T.M. Designation: C 112) of the American Society for Testing Materials.[3]

EXPLANATORY NOTES

NOTE 1.—Color of tile varies with the type of clay used and degree of burning; hence, it cannot be taken as indicative of classification until after it has been related to absorption and strength by actual tests.

NOTE 2.—The following average weights of structural clay load-bearing wall tile are given only as information:

Nominal Horizontal Thickness of Tile as Laid in Wall, in.	Average Weight, lb. per sq. ft. of tile[a]
4	20
6	30
8	36
10	42
12	52

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[a] The weights given in the above table are for scored tile. If any of the faces are not scored, the weights are increased 1 lb. per sq. ft. of unscored area.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A76.1-1942

Standard Specifications for

STRUCTURAL CLAY NON-LOAD-BEARING TILE[1]

A.S.T.M. Designation: C 56 - 41

ADOPTED, 1936; REVISED, 1939, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 56; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover structural clay non-load-bearing tile (partition, fireproofing, and furring) made from surface clay, shale, fire clay, or mixtures thereof. One grade of tile is covered, designated grade NB.

(*b*) Fireproofing tile intended for use in load-bearing masonry shall conform to the Standard Specifications for Structural Clay Load-Bearing Wall Tile (A.S.T.M. Designation: C 34) of the American Society for Testing Materials.[3]

(*c*) If tile having a particular color (Note), texture, or finish are desired, these features should be specified separately by the purchaser.

NOTE.—Color of tile varies with the type of clay used and degree of burning; hence, it cannot be taken as indicative of classification until after it has been related to absorption by actual tests.

Absorption

2. Structural clay non-load-bearing tile shall conform to the following requirements as to absorption:

Grade	Absorption,[a] per cent		
	Average of Five Tests	Individual Maximum	Individual Minimum
NB.....	5 to 25	28	4

[a] The range in percentage absorption for tile delivered to any one job shall be not more than 12.

Number of Cells and Weights

3. (*a*) Partition and split furring tile shall conform to the requirements prescribed in Table I as to total number of cells, number of cells in the direction of wall thickness, and dry weights per square foot of tile.

(*b*) The requirements for minimum weights of structural clay non-load-bearing tile shall be waived if the overall thickness of the shells, measured between the inner and extreme outer sur-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1924 to 1930, being revised in 1926, 1927, 1928, and 1930. They were adopted in 1930, revised in 1931, but withdrawn and replaced in 1934 by C 56 - 34 T which was published as tentative from 1933 to 1936, being revised in 1934, 1935, and 1936.

faces, is not less than $\frac{5}{8}$ in. and the thickness of the webs is not less than $\frac{1}{2}$ in.

TABLE I.—NUMBER OF CELLS AND WEIGHT OF TILE.

Dimensions, in.	Minimum Number of Cells		Minimum Weight,[a] lb. per sq. ft. of tile	
	In Unit	In Direction of Wall Thickness	Average	Individual
PARTITION TILE				
2 by 12 by 12	3	1	14	13
3 by 12 by 12	3	1	15	14
4 by 12 by 12	3	1	16	15
6 by 12 by 12	3	1	22	21
6 by 12 by 12	4	2	25	24
8 by 12 by 12	4	2	30	28
10 by 12 by 12	4	2	35	33
12 by 12 by 12	4	2	40	38
SPLIT FURRING TILE				
1½ by 12 by 12	3	..	7½	7
2 by 12 by 12	3	..	8	7½

[a] The weights given in the table are for scored tile. If any of the faces are unscored, the weights shall be increased 0.5 lb. per square foot of unscored area.

Permissible Variations in Dimensions

4. No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form or size of tile.

Fireproofing Tile

5. Tile intended for use in fireproofing structural members shall be of such sizes and shapes that they can be erected to cover completely the exposed surfaces of the members.

Scoring

6. Surfaces of all tile intended for the direct application of plaster or stucco shall be scratched or scored. When scored, each groove shall be not less than $\frac{1}{8}$ nor more than $\frac{3}{16}$ in. in depth, nor more than 1 in. in width. The area covered by the grooves shall not exceed 50 per cent of the area of the scored faces.

Marking

7. All non-load-bearing tile shall bear the name, initials, or trade mark of the manufacturer. These marks shall be indented on the exterior of the tile and shall be legible.

Visual Inspection

8. (*a*) All tile shall be reasonably free from laminations and from cracks, blisters, surface roughness, and other defects that would interfere with the proper setting of the tile or impair the strength or permanence of the construction.

(*b*) When unscored (smooth) tile are specified, the requirements, except as to scoring, shall be the same as for scored tile. If closer tolerances on dimensions and on freedom from belt marks, chips, surface discolorations, and roughness are desired, such requirements shall be clearly defined in supplementary specifications.

Rejection

9. In case the shipment fails to conform to the requirements, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to meet the requirements, the entire lot shall be rejected.

Expense of Tests

10. Except as specified in Section 9, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

Sampling and Testing

11. (*a*) The purchaser or his authorized representative shall be accorded proper facilities for sampling and inspection of units both at the place of manu-

facture and at the site of the work. At least ten days from the time of sampling should be allowed for completion of the tests.

(*b*) Tile shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Structural Clay Tile (A.S.T.M. Designation: C 112) of the American Society for Testing Materials.[3]

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A77.1-1942

Standard Specifications for

STRUCTURAL CLAY FLOOR TILE[1]

A.S.T.M. Designation: C 57 – 39

ADOPTED, 1936; REVISED, 1939.[2]
Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 57; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover structural clay floor tile made from surface clay, shale, fire clay, or mixtures thereof. Two grades of tile are covered, designated grade *FT1* and grade *FT2*. Both grades are suitable for use in flat or segmental arches or in combination tile and concrete ribbed-slab construction.

(*b*) If tile having a particular color (Note), texture, or finish are desired, these features should be specified separately by the purchaser.

NOTE—Color of tile varies with the type of clay used and degree of burning; hence, it cannot be taken as indicative of classification until after it has been related to absorption and strength by actual tests.

Physical Properties

2. (*a*) Structural clay floor tile shall conform to the requirements as to physical properties for the grade specified as prescribed in Table I.

(*b*) End-construction floor tile are tile designed to resist forces applied in a direction parallel to axes of the cells. Side-construction floor tile are tile designed to resist forces applied in a direction perpendicular to axes of the cells. Where end-construction tile are used on the side, they shall conform to the requirements of side-construction tile and *vice versa*.

TABLE I.—PHYSICAL REQUIREMENTS.

Grade	Absorption,[a] per cent			Compressive Strength (Based on Net Area),[b] psi.			
				End-Construction Tile		Side-Construction Tile	
	Average of Five Tests	Individual Maximum	Individual Minimum	Minimum Average of Five Tests	Individual Minimum	Minimum Average of Five Tests	Individual Minimum
FT1	5 to 25	25	4	3200	2250	1600	1100
FT2	5 to 25	25	4	2000	1400	1200	850

[a] The range in percentage absorption for tile delivered to any one job shall be not more than 12.
[b] Net area of a unit shall be taken as the area of solid material in shells and webs actually carrying stresses in a direction parallel to the direction of loading.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1924 to 1927, being revised in 1927. They were adopted in 1927, revised in 1930 and 1931, but withdrawn and replaced in 1934 by C 57 – 34 T which was published as tentative from 1933 to 1936, being revised in 1934, 1935, and 1936.

Number of Cells and Weights

3. (*a*) Flat and segmental arch tile shall conform to the requirements prescribed in Table II as to number of cells in the depth of arch, and average dry weights per square foot of tile.

TABLE II.—NUMBER OF CELLS AND WEIGHT OF TILE FOR USE IN ARCHES.

Depth of Arch, in.	Minimum Number of Cells in Depth of Arch	Average Dry Weight, lb. per sq. ft. of tile	
		Minimum	Maximum
FLAT ARCH TILE			
6	1	25	29
7	1	28	34
8	2	30	36
9	2	31	37
10	2	33	39
11	2	36	43
12	2	38	45
13	3	41	48
14	3	44	52
15	3	45	53
16	3	49	58
SEGMENTAL ARCH TILE			
6	2	28	34
8	2	34	40

(*b*) Tile designed to resist stresses in combination tile and concrete ribbed-slab construction shall conform to the requirements prescribed in Table III as to number of cells in the direction of depth of slab, and average dry weights per square foot of tile.

(*c*) The requirements for minimum weights of structural clay floor tile shall be waived if the over-all thickness of the shells, measured between the inner and extreme outer surfaces, is not less than $\frac{5}{8}$ in. and the thickness of the webs is not less than $\frac{1}{2}$ in.

Permissible Variations in Dimension

4. No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form or size of tile.

Visual Inspection

5. All tile shall be reasonably free from laminations and from cracks, blisters, surface roughness, and other defects that would interfere with the proper setting of the tile or impair the strength or permanence of the construction.

TABLE III.—NUMBER OF CELLS AND WEIGHT OF TILE FOR SLAB CONSTRUCTION.

Thickness of Units, in.	Minimum Number of Cells[a] in Thickness of Tile	Average Dry[b] Weight, lb. per sq. ft. of tile	
		Minimum	Maximum
3	1	13.5	16.5
4	1	14.5	17.5
5	1	17.0	21.0
5	2	20.5	25.5
6	1	20.0	24.0
6	2	22.5	27.5
7	1	21.5	26.5
7	2	24.5	29.5
8	1	24.5	29.5
8	2	26.0	32.0
9	2	28.0	34.0
9	3	32.5	39.5
10	2	29.5	36.5
10	3	34.0	42.0
12	2	36.0	44.0
12	3	40.5	49.5

[a] Cells are hollow spaces enclosed within the perimeter of the exterior shells, and having a minimum dimension of not less than $\frac{1}{4}$ in. and a cross-sectional area of not less than 1 sq. in.

[b] The weights given in the table are for scored tile. If any of the faces are unscored, the weights shall be increased 0.5 lb. per sq. ft. of unscored area.

Scoring

6. Surfaces of all tile intended for the direct application of plaster shall be scratched or scored. When scored, each groove shall be not less than $\frac{1}{4}$ nor more than $\frac{3}{16}$ in. in depth, and not more than 1 in. in width. The area covered by the grooves shall not exceed 50 per cent of the area of the scored faces.

Marking

7. All floor tile shall bear the name, initials, or trade mark of the manufacturer. These marks shall be indented on the exterior of the tile and shall be legible.

Rejection

8. In case the shipment fails to conform to the requirements for the grade specified, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to meet the requirements, the entire lot shall be rejected.

Expense of Tests

9. Except as specified in Section 8, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

Sampling and Testing

10. (*a*) The purchaser or his authorized representative shall be accorded proper facilities for sampling and inspection of units both at the place of manufacture and at the site of the work. At least ten days from the time of sampling should be allowed for completion of the tests.

(*b*) Tile shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Structural Clay Tile (A.S.T.M. Designation: C 112) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A83.1-1942

Standard Methods of

SAMPLING AND TESTING STRUCTURAL CLAY TILE[1]

A.S.T.M. Designation: C 112 - 36

ADOPTED, 1936.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 112; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the sampling and testing of structural clay tile for weight determinations, compressive strength, absorption, and freezing and thawing.

Definitions of Terms

2. The Standard Definitions of Terms Relating to Methods of Testing (A.S.T.M. Designation: E 6) of the American Society for Testing Materials[3] shall be considered as applying to the terms used in these methods.

SAMPLING

Selection of Test Specimens

3. For purpose of tests, full-size tile shall be selected by the purchaser or by his authorized representative. Specimens shall be representative of the whole lot of tile from which they are selected.

Number of Specimens

4. For the weight determination, compressive strength, absorption, and freezing-and-thawing tests, at least five tile shall be selected from each kiln or from each lot of 100 tons or fraction thereof. In no case shall less than five tile be taken. Additional specimens may be taken at the discretion of the purchaser.

Identification

5. Each specimen shall be marked so that it may be identified at any time. Markings shall not cover more than 5 per cent of the superficial area of the specimen.

WEIGHT DETERMINATION

Test Specimens

6. Five full-size tile shall be tested.

Procedure

7. The five tile specimens, if not in kiln-dry condition, shall be dried to constant weight in a ventilated oven at 110 to 115 C. (230 to 239 F.) and shall then be weighed separately. The balance used shall be accurate to within 0.5 per cent of the weight of the smallest specimen tested.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these methods were published as tentative from 1934 to 1936, being revised in 1935 and 1936.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Calculations and Reports

8. (*a*) The weight per unit area of a tile specimen shall be calculated by dividing the total weight in pounds by the average area in square feet of the two faces of the tile as laid in the masonry.

(*b*) The results shall be reported separately for each tile with the average for the five tile.

COMPRESSIVE STRENGTH

Test Specimens

9. Five dry full-size tile shall be tested.

Capping Test Specimens

10. (*a*) Bearing surfaces of the test specimens and portions adjoining them which are liable to absorb water from the plastic capping mortar shall be coated with shellac and allowed to dry. A quantity of plastic mortar, made of unretarded gypsum (plaster of Paris) mixed with sufficient water to spread evenly, shall be placed on a plane surface which has been coated with oil. The surface to be capped shall be placed on this mortar, and the specimen, so held that its axis is at right angles to the capping surface, shall be firmly pressed down with a single motion.

(*b*) The average thickness of the cap after the extruded capping mortar has been removed and the edges trued shall be not more than $\frac{1}{8}$ in. Patching of caps after setting shall not be permitted. Imperfect caps shall be removed and replaced with new ones.

(*c*) When specimens have portions of bearing surfaces in different planes, these surfaces shall be made plane and approximately parallel by means of a filling of mortar composed of one part by weight of a quick-hardening cement, conforming to the requirements for type III cement in the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials,[2] and two parts of sand. The filling shall be aged for 1 day, after which the specimens shall be capped as specified in Paragraph (*a*).

(*d*) The caps shall be aged at least 2 days before the specimens are tested.

Procedure

11. (*a*) *Position of Specimens.*—All specimens shall be tested in a position such that the load is applied in the same direction as in service.

(*b*) *Testing Machine.*—The testing machine shall conform to the requirements of the Standard Methods of Verification of Testing Machines (A.S.T.M. Designation: E 4) of the American Society for Testing Materials.[3]

(*c*) *Bearing Block.*—The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to turn in any direction. The diameter of the bearing surface shall be at least 6 in. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. The bearing block surfaces intended for contact with the specimen should have a hardness not less than C60 Rockwell number (Brinell number 620). These surfaces shall not depart from plane surfaces by more than 0.001 in. When the bearing area of the spherical bearing block is not sufficient to cover the area of the specimen, a steel plate with surfaces machined to true planes within plus or minus 0.001 in., and with a thickness equal to at least one-third of the distance

from the edge of the spherical bearing to the most distant corner, shall be placed between the spherical bearing block and the capped specimen.

(*d*) *Speed of Testing.*—The speed of the moving head of the testing machine shall be not more than 0.05 in. per min.

Calculations and Report

12. (*a*) The compressive strength of load-bearing wall tile shall be taken as the maximum load in pounds, divided by the gross cross-sectional area of the tile in square inches. The gross area of a tile is the total area of a section perpendicular to the direction of the load, including areas within cells and within re-entrant spaces unless these spaces are to be occupied in the masonry by portions of adjacent masonry.

(*b*) The compressive strengths of floor tile and non-load-bearing tile shall be taken as the maximum load in pounds, divided by the net cross-sectional area in square inches. The net area of a tile is the area of the fired clay in the section of minimum area taken perpendicular to the direction of the load.

(*c*) The results shall be reported separately for each tile, with the average for the five tile.

ABSORPTION

Test Specimens

13. The specimens for the absorption test shall consist of five tile or three representative pieces from each of these five tile. If small pieces are used, two shall be taken from the shell and one from an interior web, the weight of each piece to be not less than 227 g. (0.5 lb.). The specimens shall have had their rough edges or loose particles ground off and be free from cracks from the failure of the tile in compression, where taken from tile which have been subjected to strength tests.

Accuracy of Weighings

14. The balance used shall be sensitive to within 0.2 per cent of the weight of the smallest specimen tested.

Procedure

15. (*a*) *Drying.*—All specimens shall be dried to constant weight in a ventilated oven at 110 to 115 C. (230 to 239 F.)

(*b*) *Saturation.*—After obtaining the dry weight of the specimens they shall be immersed in soft, distilled, or rain water, the temperature raised to the boiling point, and the water boiled continuously for 1 hr. The specimens shall then be allowed to cool in the water to room temperature.

(*c*) *Weighing.*—After saturation, the specimens shall be removed from the water and allowed to drain for not more than 1 min. The superficial water shall then be removed from the specimens with a damp cloth, after which they shall be weighed immediately.

Calculations and Report

16. The absorption shall be calculated as a percentage of the initial dry weight, carried to the nearest first decimal place. The results shall be reported separately for each tile, with the average for the five tile.

FREEZING AND THAWING

Preparation of Specimens

17. The specimens for the freezing-and-thawing test shall consist of five tile or of a cell not less than 4 in. in length sawed from each of these five tile. The specimens shall be saturated by immersion in cold water for at least 72 hr. prior to starting the freezing.

Procedure

18. Any practical method of obtaining alternate freezings and thawings may

be used, the freezings always to be made with fully saturated specimens and the time and temperature to be such as to insure full freezing and thawing throughout the specimen. The initial weighing and all weighings for loss of weight shall be made on dry specimens.

Accuracy of Weighings

19. The balance used shall be sensitive to within 0.1 per cent of the weight of the smallest specimen tested.

Interpretation of Results

20. Failure under the freezing-and-thawing treatment shall be considered to be reached when:

(*a*) The specimens show superficial disintegration or spalling with loss of weight of more than 5 per cent of the initial weight,

(*b*) The specimens are badly cracked, or

(*c*) The specimens show evident loss of structural strength.

Standard Definitions of

TERMS RELATING TO STRUCTURAL CLAY TILE[1]

A.S.T.M. Designation: C 43 - 36

ADOPTED, 1936.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 43; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

TILE

Structural Clay Tile.—Hollow burned-clay masonry building units with parallel cells.

NOTE.—The term "tile" is understood, within the meaning of these definitions, to mean "structural clay tile." The term "terra cotta," which is applied to ornamental building units of burned clay, should not be used to designate structural clay tile.

Load-Bearing Tile.—Tile for use as load-bearing structural units in masonry walls.

Fireproofing Tile.—Tile for use as a protection for structural members against fire.

Partition Tile.—Tile for use in building interior partitions, subdividing areas into rooms, or similar construction, and carrying no superimposed loads.

Furring Tile.—Tile for lining the inside of walls and carrying no superimposed loads.

Foundation Tile.—Tile for use as load-bearing structural units in foundation walls.

Floor Tile.—Tile for use as structural units in floor and roof construction.

Bonding Tile.—Tile designed to provide recesses for header brick in brick-faced walls.

Book Tile.—Tile with tongue and groove edges resembling a book in shape.

GENERAL TERMS

Side-Construction Tile.—Tile designed to receive its principal stress at right angles to the axes of the cells.

End-Construction Tile.—Tile designed to receive its principal stress parallel to the axes of the cells.

Salt-Glazed Tile.—Tile with vitreous glaze on its surface produced by burning salt in the kiln at the temperature used in finishing the burning.

Porous Structural Clay Tile.—Tile in which the natural porosity of the clay has been increased by the admixture of other ingredients.

RAW MATERIALS

Shale.—A thinly stratified, consolidated, sedimentary clay[3] with well-marked cleavage parallel to the bedding.

Fire Clay.—A sedimentary clay[3] of low flux content.

NOTE.—Fire clay is usually associated with coal measures.

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to their present adoption as standard, these definitions were published as tentative from 1921 to 1924, being revised in 1923 and 1926. They were adopted in 1924, revised in 1931, but withdrawn and republished as tentative from 1933 to 1936, being revised in 1934.

[3] The definitions for the terms "shale," "fire clay" and "surface clay" are based upon the following definition of the term "clay."

Clay.—An earthy or stony mineral aggregate consisting essentially of hydrous silicates of alumina, plastic when sufficiently pulverized and wetted, rigid when dry, and vitreous when fired to a sufficiently high temperature.

Surface Clay.—An unconsolidated, unstratified clay,[3] occurring on the surface.

DESIGNATION OF DIMENSIONS

Thickness.—That dimension designed to lie at right angles to the face of the wall, floor, or other member in which it is used.

Width.—That dimension measured at right angles to the direction of its thickness and length.

Length.—That dimension measured between the cut ends.

NOTE 1.—In practice, the first dimension given represents thickness; the second, width; the third, length.

NOTE 2.—Gross area is taken as total area enclosed by the outside dimensions of the unit in a direction perpendicular to that in which load is carried.

NOTE 3.—Net area shall be taken as the area of solid material in shells and webs actually carrying stresses through the units in a direction parallel to the direction of loading.

PARTS, OPENINGS, AND SURFACE FEATURES

Shell.—The outer walls.

Webs.—The partitions dividing it into cells.

Cells.—Hollow spaces enclosed within the perimeter of the exterior shells and having a minimum dimension of not less than ½ in. and a cross-sectional area of not less than 1 sq. in.

Scoring.—The grooves formed in the exterior faces of the shells to increase the bond of mortar, plaster, or stucco.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A79.1-1944

Standard Specifications for

HOLLOW LOAD-BEARING CONCRETE MASONRY UNITS[1]

A.S.T.M. Designation: C 90 – 44

ADOPTED, 1936; REVISED, 1939, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 90; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover hollow load-bearing concrete masonry wall units made from portland cement and suitable aggregates such as sand, gravel, crushed stone, bituminous or anthracite cinders, burned clay or shale, and blast-furnace slag.[3]

NOTE.—When a particular surface texture, finish, or uniformity of color is desired, these features should be specified separately by the purchaser.

Cinder Aggregate

2. The combustible content present in cinder aggregate shall not exceed 35 per cent of the weight of the aggregate.

Physical Requirements

3. At the time of delivery to the site of the work the units shall conform to the physical requirements prescribed in Table I.

TABLE I.—PHYSICAL REQUIREMENTS.

Minimum Face Shell Thickness, in.	Compressive Strength, min., psi. (Average Gross Area)		Water Absorption, max., lb. per cu. ft.	Moisture Content, max., per cent
	Average of 5 Units	Individual Unit	Average of 5 Units	Average of 5 Units
1¼ or over:				
Grade A[a]	1000	800	15	40
Grade B[b]	700	600	..	40
Under 1¼ and over ¾	1000	800	15	40

[a] For use in exterior walls below grade, and for unprotected exterior walls above grade.

[b] For general use above grade where protected from the weather with two coats of portland cement paint or other satisfactory waterproofing treatment approved by the purchaser.

Permissible Variations in Dimensions

4. No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form of unit.

Visual Inspection

5. (*a*) All units shall be sound and free from cracks or other defects that would interfere with the proper placing of the unit or impair the strength or permanence of the construction.

(*b*) Units that are intended to serve as a base for plaster or stucco shall have a sufficiently rough surface to afford good bond.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1931 to 1936, being revised in 1933 and 1934.

[3] When fire tests are required they shall be conducted in accordance with the Standard Methods of Fire Tests of Building Construction and Materials (A.S.T.M. Designation: C 19), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Marking

6. All units shall bear a distinctive mark of the manufacturer or shall be otherwise readily identified as to origin.

Sampling and Testing

7. (*a*) The purchaser or his authorized representative shall be accorded proper facilities to inspect and sample the units at the place of manufacture from the lots ready for delivery. At least ten days should be allowed for completion of the tests.

(*b*) Units shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Concrete Masonry Units (A.S.T.M. Designation: C 140) of the American Society for Testing Materials.[4]

Rejection

8. In case the shipment fails to conform to the requirements, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to conform to the test requirements, the entire lot shall be rejected.

Expense of Tests

9. Except as specified in Section 8, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

---

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A80.1-1942

Standard Specifications for

HOLLOW NON-LOAD-BEARING CONCRETE MASONRY UNITS[1]

A.S.T.M. Designation: C 129 - 39

ADOPTED, 1939.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 129; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover hollow non-load-bearing concrete masonry wall units made from portland cement and suitable aggregates such as sand, gravel, crushed stone, bituminous or anthracite cinders, burned clay or shale, and blast-furnace slag.

NOTE.—When a particular surface texture, finish, or uniformity of color is desired, these features should be specified separately by the purchaser.

Cinder Aggregate

2. The combustible content present in cinder aggregate shall not exceed 35 per cent of the weight of the aggregate.

Physical Requirements

3. At the time of delivery to the site of the work the units shall conform to the physical requirements prescribed in Table I.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1937 to 1939, being revised in 1938 and 1939.

Dimensions and Permissible Variations

4. (*a*) Minimum face shell thickness shall be not less than $\frac{1}{2}$ in.

(*b*) No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form of unit.

Visual Inspection

5. (*a*) All units shall be sound and free from cracks or other defects that would interfere with the proper placing of the unit.

TABLE I.—PHYSICAL REQUIREMENTS.

Compressive Strength, min., psi. (Average Gross Area)		Moisture Content, max., per cent of total absorption
Average of 5 Units	Individual Unit	Average of 5 Units
350	300	40

(*b*) Units that are intended to serve as a base for plaster or stucco shall have a sufficiently rough surface to afford good bond.

Marking

6. All units shall bear a distinctive mark of the manufacturer or shall be otherwise readily identified as to origin.

Sampling and Testing

7. (*a*) The purchaser or his authorized representative shall be accorded proper facilities to inspect and sample the units at the place of manufacture from the lots ready for delivery. At least ten days should be allowed for completion of the tests.

(*b*) Units shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Concrete Masonry Units (A.S.T.M. Designation: C 140) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Rejection

8. In case the shipment fails to conform to the requirements, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to conform to the test requirements, the entire lot shall be rejected.

Expense of Tests

9. Except as specified in Section 8, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A81.1-1942

Standard Specifications for

SOLID LOAD-BEARING CONCRETE MASONRY UNITS[1]

A.S.T.M. Designation: C 145 - 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 145; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover solid load-bearing concrete masonry wall units (concrete block or tile units with 75 per cent or more net area) made from portland cement and suitable aggregates such as sand, gravel, crushed stone, bituminous or anthracite cinders, burned clay or shale, and blast-furnace slag.[3] Two grades of units are covered: grade A and grade B.

NOTE.—When a particular surface texture, finish, or uniformity of color is desired, these features should be specified separately by the purchaser.

Cinder Aggregate

2. The combustible content present in cinder aggregate shall not exceed 35 per cent of the weight of the aggregate.

Physical Requirements

3. (*a*) At the time of delivery to the site of the work the units shall conform to the physical requirements for the grades specified, as prescribed in Table I.

(*b*) Units that are not exposed to the weather or soil in the finished work need not conform to the absorption requirement prescribed in Table I.

TABLE I.—PHYSICAL REQUIREMENTS.

	Compressive Strength, min., psi. (Average Gross Area)		Water Absorption, max., lb. per cu. ft.	Moisture Content, max., per cent
	Average of 5 Units	Individual Unit	Average of 5 Units	Average of 5 Units
Grade A.....	1800	1600	15	40
Grade B.....	1200	1000	15	40

NOTE.—The above classification is based on strength and does not necessarily measure weather resistance.

Dimensions and Permissible Variations

4. (*a*) The average net area of the unit shall not be less than 75 per cent of the gross area.

(*b*) No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form of unit.

Visual Inspection

5. (*a*) All units shall be sound and free from cracks or other defects that would interfere with the proper placing of the unit, or impair the strength or permanence of the construction.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1939 to 1940.

[3] When fire tests are required they shall be conducted in accordance with the Standard Methods of Fire Tests of Building Construction and Materials (A.S.T.M. Designation: C 19), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) Units that are intended to serve as a base for plaster or stucco shall have a sufficiently rough surface to afford good bond.

Marking

6. All units shall bear a distinctive mark of the manufacturer or shall be otherwise readily identified as to origin.

Sampling and Testing

7. (*a*) The purchaser or his authorized representative shall be accorded proper facilities to inspect and sample the units at the place of manufacture from the lots ready for delivery. At least ten days should be allowed for completion of the tests.

(*b*) Units shall be sampled and tested in accordance with the Standard Methods of Sampling and Testing Concrete Masonry Units (A.S.T.M. Designation: C 140) of the American Society for Testing Materials.[4]

Rejection

8. In case the shipment fails to conform to the requirements, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to conform to the test requirements, the entire lot shall be rejected.

Expense of Tests

9. Except as specified in Section 8, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A73.1-1942

Standard Specifications for

CONCRETE MASONRY UNITS FOR CONSTRUCTION OF CATCH BASINS AND MANHOLES[1]

A.S.T.M. Designation: C 139 - 39

ADOPTED, 1939.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 139; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover solid, precast, segmental concrete masonry units made from portland cement and suitable aggregates such as sand, gravel, crushed stone, and air-cooled blast-furnace slag. The units are intended for use in the construction of catch basins and manholes.

Physical Requirements

2. At the time of delivery to the site of the work the units shall conform to the physical requirements prescribed in Table I.

TABLE I.—PHYSICAL REQUIREMENTS.

Compressive Strength, min., psi. (Average Gross Area)		Water Absorption, max. per cent	
Average of 5 Units	Individual Unit	Average of 5 Units	Individual Unit
2500	2000	8	10

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these specifications were published as tentative from 1938 to 1939.

Dimensions and Permissible Variations

3. (*a*) The thickness of unit shall be not less than 5 in.

(*b*) No over-all dimension shall vary more than 3 per cent over or under the specified dimension for any form of unit.

Visual Inspection

4. All units shall be sound and free from cracks or other defects that would interfere with the proper placing of the unit.

Marking

5. All units shall bear a distinctive mark of the manufacturer or shall be otherwise readily identified as to origin.

Sampling and Testing

6. (*a*) The purchaser of his authorized representative shall be accorded proper facilities to inspect and sample the units at the place of manufacture from the lots ready for delivery. At least ten days should be allowed for completion of the tests.

(*b*) Units shall be sampled and tested in accordance with the Standard Meth-

ods of Sampling and Testing Concrete Masonry Units (A.S.T.M. Designation: C 140) of the American Society for Testing Materials.[3]

Rejection

7. In case the shipment fails to conform to the requirements, the manufacturer may sort it, and new specimens shall be selected by the purchaser from the retained lot and tested at the expense of the manufacturer. In case the second set of specimens fails to conform to the test requirements, the entire lot shall be rejected.

Expense of Tests

8. Except as specified in Section 7, and unless otherwise agreed, the expense of inspection and testing shall be borne by the purchaser.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A84.1-1942

Standard Methods of

SAMPLING AND TESTING CONCRETE MASONRY UNITS[1]

A.S.T.M. Designation: C 140 - 39

ADOPTED, 1939.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation C 140; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the sampling and testing of concrete masonry units for compressive strength, absorption, weight, and moisture content.

NOTE.—Procedures for the sampling and testing of concrete brick are covered in the Standard Methods of Sampling and Testing Brick (A.S.T.M. Designation: C 67) of the American Society for Testing Materials.[3]

Definitions of Terms

2. The Standard Definitions of Terms Relating to Methods of Testing (A.S.T.M. Designation: E 6) of the American Society for Testing Materials[3] shall be considered as applying to the terms used in these methods.

SAMPLING

Selection of Test Specimens

3. For purpose of tests, full-size concrete masonry units shall be selected by the purchaser or by his authorized representative. Specimens shall be representative of the whole lot of units from which they are selected. If test specimens are selected at the site of the work, units for moisture content tests shall be taken within 48 hr. after delivery.

Number of Specimens

4. For the strength, absorption and moisture content determinations, 10 individual units shall be selected from each lot of 10,000 units or fraction thereof and 20 individual units from each lot of more than 10,000 and less than 100,000 units. For lots of more than 100,000 units 10 individual units shall be selected from each 50,000 units or fraction thereof contained in the lot. In no case shall less than 10 units be taken. Additional specimens may be taken at the discretion of the purchaser.

Identification

5. (*a*) Each specimen shall be marked so that it may be identified at any time. Markings shall not cover more than 5 per cent of the superficial area of the specimen.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-15 on Manufactured Masonry Units.

[2] Prior to adoption as standard, these methods were published as tentative from 1938 to 1939, being revised in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) Units for moisture content tests shall be weighed immediately after sampling and marking.

COMPRESSIVE STRENGTH

Test Specimens

6. Five air-dry full-size units shall be tested.

Capping Test Specimens

7. (*a*) A quantity of plastic capping mortar, made of one part (by volume) of portland cement and one part of calcined gypsum (plaster of Paris) mixed with sufficient water to spread evenly, shall be placed on a plane surface which has been coated with oil. The surface to be capped shall be placed on this mortar, and the specimen, so held that its axis is at right angles to the capping surface, shall be firmly pressed down with a single motion.

(*b*) The average thickness of the cap after the extruded capping mortar has been removed and the edges trued shall be not more than $\frac{1}{8}$ in. Patching of caps after setting shall not be permitted. Imperfect caps shall be removed and replaced with new ones.

(*c*) The caps shall be aged at least 6 hr. before the specimens are tested.

Procedure

8. (*a*) *Position of Specimens.*—All specimens shall be tested in a position such that the load is applied in the same direction as in service.

(*b*) *Testing Machine.*—The testing machine shall conform to the requirements of the Standard Methods of Verification of Testing Machines (A.S.T.M. Designation: E 4) of the American Society for Testing Materials.[3]

(*c*) *Bearing Blocks.*—The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to turn in any direction. The diameter of the bearing surface shall be at least 6 in. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. The bearing block surfaces intended for contact with the specimen should have a hardness not less than C60 Rockwell number (Brinell number 620). These surfaces shall not depart from plane surfaces by more than 0.001 in. When the bearing area of the spherical bearing block is not sufficient to cover the area of the specimen, a steel plate with surfaces machined to true planes within plus or minus 0.001 in., and with a thickness equal to at least one-third of the distance from the edge of the spherical bearing to the most distant corner, shall be placed between the spherical bearing block and the capped specimen.

(*d*) *Speed of Testing.*—The speed of the moving head of the testing machine shall be not more than 0.05 in. per min.

Calculations and Report

9. (*a*) The compressive strength of a concrete masonry unit shall be taken as the maximum load in pounds divided by the gross cross-sectional area of the unit in square inches. The gross area of a unit is the total area of a section perpendicular to the direction of the load, including areas within cells and within re-entrant spaces unless these spaces are to be occupied in the masonry by portions of adjacent masonry.

(*b*) *Net Area.*—The average percentage of net area of the unit is equal to the

net volume divided by the gross volume and multiplied by 100:

$$\text{Net area, per cent} = \frac{\text{net vol.} \times 100}{\text{gross vol.}}$$

$$\text{Net volume, cu. ft.} = \frac{\text{dry wt. of unit}}{\text{wt. per cu. ft.}}$$

$$\text{Gross volume, cu. ft.} = \frac{T \times H \times L}{1728}$$

$$\text{Weight per cu. ft., lb.} = \frac{\text{dry wt.} \times 62.4}{\text{wet wt.} - \text{suspended immersion wt.}}$$

where:

T = thickness of the unit in inches,
H = height of the unit in inches, and
L = length of the unit in inches.

(*c*) The results shall be reported separately for each unit, with the average for the five units.

ABSORPTION

Test Specimens

10. Five full-size units shall be used.

Accuracy of Weighings

11. The balance used shall be sensitive to within 0.5 per cent of the weight of the smallest specimen tested.

Procedure

12. (*a*) *Saturation.*—The test specimens shall be completely immersed in water at room temperature at from 15.6 to 26.7 C. (60 to 80 F.) for 24 hr. The specimens shall then be weighed while suspended with a metal wire and completely submerged in water. They shall be removed from the water and allowed to drain for 1 min. by placing on a $\frac{3}{8}$-in. or coarser wire mesh, visible surface water being removed with a damp cloth, and immediately weighed.

(*b*) *Drying.*—Subsequent to saturation all specimens shall be dried in a drier or oven at 100 to 115 C. (212 to 239 F.) and weighed at 24-hr. intervals until the loss in weight does not exceed 1 per cent in a 24-hr. period.

Calculations and Report

13. (*a*) *Absorption.*—The absorption in pounds per cubic foot of concrete is equal to 62.4 times the difference between the wet and dry weights divided by the difference between the wet weight and the suspended weight immersed:

$$\text{Absorption, lb. per cu. ft.} = \frac{(\text{wet wt.} - \text{dry wt.}) \times 62.4}{(\text{wet wt.} - \text{suspended wt. immersed})}$$

The absorption expressed as a percentage of the dry weight is equal to the difference between the wet and dry weights divided by the dry weight and multiplied by 100:

$$\text{Absorption, per cent} = \frac{(\text{wet wt.} - \text{dry wt.}) \times 100}{\text{dry wt.}}$$

(*b*) *Moisture Content.*—The moisture content of the units at time of sampling (expressed as a percentage of the total absorption) is the difference between the average weight as sampled and the average dry weight divided by the difference between the average wet weight and the average dry weight and multiplied by 100:

$$\text{Moisture content, per cent} = \frac{(\text{sampled wt.} - \text{dry wt.}) \times 100}{(\text{wet wt.} - \text{dry wt.})}$$

(*c*) *Report.*—The results shall be reported separately for each unit, with the average for the five units.

Standard Methods of Test for

ABSORPTION AND APPARENT SPECIFIC GRAVITY OF NATURAL BUILDING STONE[1]

A.S.T.M. Designation: C 97 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 97; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover the procedures for determining the absorption by weight or by volume, and the apparent specific gravity of natural building stones used for exterior or interior construction or decorative purposes. The calculation of the dry weight of the stone in pounds per cubic foot may also be made from the results of the apparent specific gravity test.

ABSORPTION

Test Specimens

2. Samples shall be supplied of sufficient size to provide not less than three test specimens of some regular form such as a cube, prism, or cylinder whose greatest dimension shall be not more than 3 in. and whose least dimension shall be not less than 2 in. All surfaces of specimens shall be smooth finished. No chisels or other hand tools shall be used in finishing specimens.

Procedure

3. (*a*) The specimens shall be dried in an oven at 110 to 120 C. for at least 24 hr.

(*b*) After drying, the specimens may be cooled in the room for 30 min. and then weighed. When the specimens cannot be weighed immediately after cooling, they shall be placed in a desiccator. The weight shall be determined to the nearest 0.05 g.

(*c*) The specimens shall be entirely immersed in distilled water at approximately 20 C. for two weeks. At the end of this period the specimens shall be removed one at a time, all faces and edges thoroughly wiped off with a damp cloth, and each specimen immediately weighed to the nearest 0.05 g.

NOTE.—The operator should distinguish between a damp cloth and a wet one. In starting the operation, the towel should be sprinkled lightly. When the surface of the specimen is properly wiped off, it should appear dry.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, these methods were published as tentative from 1930 to 1936, being revised in 1931. Editorially revised and rearranged in 1939.

Calculations and Report

4. (*a*) The percentage of absorption shall be calculated as follows:

$$\text{Absorption, per cent} = \frac{B - A}{A} \times 100$$

where:

A = weight of the dried specimen, and

B = weight of the specimen after immersion.

(*b*) In general, the average of all the tests shall be reported as the absorption of the stone. Individual determinations which differ by more than 25 per cent from the average of all the determinations may be disregarded when there is evidence that such results are of uncertain value. The absorption shall then be reported as the average of the remaining determinations, but all determinations shall be reported as information.

(*c*) The absorption value obtained from this test is the percentage absorption by weight. To convert the result to percentage absorption by volume, multiply by the value of the apparent specific gravity as determined with the same specimens in accordance with Sections 5 and 6.

(*d*) The report of the absorption test shall state whether the absorption has been determined according to weight or volume and, if the percentage of volume absorption is reported, there shall also be reported the percentage absorption by weight and the apparent specific gravity.

APPARENT SPECIFIC GRAVITY

Weighing

5. To obtain the apparent specific gravity, the weight of the specimen suspended in water shall be determined immediately after the weighing of the specimen described in Section 3.

NOTE.—When weighing the specimen suspended in water, various methods of suspending the specimen from the balance beam are in use. Fine silk thread or a cradle of light wire whose weight has been carefully determined may be convenient. The cradle should be of such construction that there will be no possibility of air bubbles forming in it. The water container should be of glass and may be supported on a platform which straddles the balance pan, this method allowing the weighings to be made without detaching the pan.

Calculations and Report

6. (*a*) The apparent specific gravity shall be calculated as follows:

$$\text{Apparent specific gravity} = \frac{A}{B - C}$$

where:

A = weight of the dried specimen,

B = weight of the wet specimen after immersion, and

C = weight of the specimen suspended in water.

(*b*) The apparent specific gravity shall be calculated for those specimens whose absorption values are to be averaged as described in Section 4 (*d*), and the average of the apparent specific gravities so calculated shall be reported as that of the stone.

NOTE.—To determine the weight of the dry stone in pounds per cubic foot, multiply the apparent specific gravity by 62.4.

Standard Method of

FLEXURE TESTING OF NATURAL BUILDING STONE[1]

DETERMINATION OF MODULUS OF RUPTURE

A.S.T.M. Designation: C 99 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 99: the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the modulus of rupture of natural building stones used for exterior or interior construction or decorative purposes.

Apparatus

2. (*a*) *Testing Machine.*—The testing machine shall be sensitive to 5 lb. when loaded to 500 lb.

(*b*) *Knife-Edges.*—For the support of the test specimen a set of knife-edges similar to those shown in Fig. 1 shall be provided. The load shall be applied through a third knife-edge of the same type.

Test Specimens

3. (*a*) Samples shall be representative of the material and shall consist of sections cut from apparently sound material, preferably quarry blocks or slabs. The direction of bedding or rift planes shall be plainly marked on the sample. The sample supplied shall be of sufficient size to provide all of the specimens required for the test.

(*b*) The test specimens shall be sawed from the sample and shall be finished as closely as practicable to 12 by 4 by 1 in. in size either by the use of grinding wheels or by hand rubbing with abrasive powders on steel plates. The 12 by 4-in. faces shall be made as nearly plane and parallel as practicable. No hand cutting with chisels or other tools shall be permitted.

Types of Specimens

4. Three or more specimens shall be prepared for each required combination of load application and bedding or rift plane direction, such as are shown in Fig. 2 and noted below:

(*1*) Load applied perpendicular to bedding or rift planes,

(*2*) Load applied parallel to bedding or rift planes, and

(*3*) Load applied perpendicular to

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

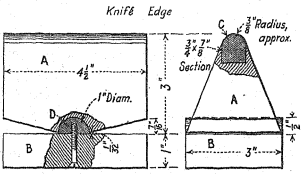
[2] Prior to adoption as standard, this method was published as tentative from 1930 to 1936, being revised in 1931. Editorially revised and rearranged in 1939.

bedding or rift planes with the bedding or rift planes vertical.

Marking Specimens

5. The load-bearing surfaces and the direction of bedding or rift planes shall be carefully marked on each specimen after finishing.

Measuring Specimens



6. The thickness and width of the specimen at the mid-section shall be measured to the nearest 0.01 in.

Conditioning

7. Before testing, the specimens shall be dried in an oven at 110 to 120 C. for 24 hr.

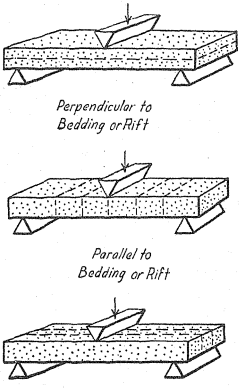
Procedure

8. The test specimen shall be supported on the knife-edges on 10-in. centers and the load applied at the center of the specimen through the third knife-edge (see Fig. 2). The load shall be applied at the rate of 100 lb. per min. The breaking load shall be recorded to the nearest 5 lb.

A, B = Cast Iron Wedges.
C, D = Cold-Rolled Steel.

FIG. 1.—Self-Adjusting Knife-Edge Bearing and Load-Application Device.

Calculations and Report



9. (*a*) The modulus of rupture shall be calculated as follows:

$$R = \frac{3wl}{2bd^2}$$

where:

R = modulus of rupture,
w = breaking load in pounds,
l = length of span in inches,
b = width of specimen in inches, and
d = thickness of specimen in inches.

(*b*) The average value of the modulus obtained from a group of not less than two specimens shall be reported as the modulus of rupture for the condition of loading and direction of bedding or rift used. In case any specimen shows a value 25 per cent lower than the average of its group, it shall be examined for defects, and if the low value appears to be due to imperfections, the average of the other specimens in the group shall be reported as the modulus of rupture of the group. All determinations shall be reported as information.

Dashed lines indicate direction of bedding or rift. Arrows indicate direction of loading.

FIG. 2.—Methods of Applying Load with Reference to Bedding or Rift.

Standard Method of Test for

MODULUS OF ELASTICITY OF NATURAL BUILDING STONE[1]

A.S.T.M. Designation: C 100 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 100; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the modulus of elasticity in compression or in flexure of natural building stones used for exterior or interior construction or decorative purposes.

Apparatus

2. (*a*) *Elasticity in Flexure.*—For determining the elasticity in flexure, the testing machine and knife-edges shall conform to the requirements prescribed in Section 2 of the Standard Method of Flexure Testing of Natural Building Stone (Determination of Modulus of Rupture) (A.S.T.M. Designation: C 99) of the American Society for Testing Materials.[3] A suitable deflectometer capable of measuring the deflection of the specimen to 0.0001 in. and of such design that it may be attached to the specimen shall be used. A measuring device of satisfactory type is shown in Fig. 1 (*b*).

(*b*) *Elasticity in Compression.*—For determining the elasticity in compression, any form of standard testing machine may be used for the compression test together with a spherical bearing block large enough to entirely cover the specimen, but not greater in diameter than three times the width of the loaded face of the specimen. A compressometer of the averaging type capable of measuring the compression of the specimen to 0.00002 in. shall be used. A measuring device of satisfactory type is shown in Fig. 1 (*a*).

Test Specimens

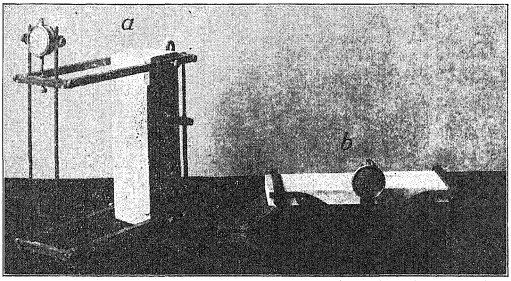
3. (*a*) Samples shall be representative of the material and shall consist of sections cut from apparently sound material, preferably quarry blocks or slabs. The direction of the bedding planes or rift shall be plainly marked on the sample. The sample shall be of sufficient size to allow the preparation of not less than three specimens having the bedding planes or rift running in

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, this method was published as tentative from 1931 to 1936. Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

the proper direction for the kind of test specified, that is, either parallel or perpendicular to the face of the specimen to which pressure is to be applied in the test.



(*b*) *Elasticity in Flexure.*—For determining elasticity in flexure, the same size and shape specimens specified in Sections 3 and 4 of the Standard Method of Flexure Testing of Natural Building Stone (Determination of Modulus of Rupture) (A.S.T.M. Designation: C 99) of the American Society for Testing Materials[3] shall be used.

Marking Specimens

4. The load-bearing surfaces and the direction of the bedding planes or rift shall be carefully marked on each specimen after finishing.

Measuring Specimens

5. The dimensions of the specimen shall be measured to the nearest 0.01 in. The width and thickness at the center section shall be used in calculating the elasticity in flexure and also in compression. The length or height of the specimen shall be recorded and the gage length used shall be measured and centered along the length or height.

(*a*) Compressometer. (*b*) Deflectometer.

FIG. 1.—Assembled Views of Apparatus for Modulus of Elasticity Test.

(*c*) *Elasticity in Compression.*—For determining elasticity in compression, prismatic pieces 3½ by 3½ by 12 in. shall be used, and the sides of the blocks shall be finished to approximate planes.

(*d*) The specimens shall be cut from the original samples with saws. No hand cutting with chisels or other tools shall be permitted. The load-bearing surfaces shall be finished to as nearly true and parallel planes as possible, grinding wheels or the use of abrasive powders and rubbing plates affording convenient means of obtaining satisfactory surfaces.

Conditioning

6. (*a*) *Dry Condition.*—Specimens to be tested in the dry condition shall be dried in an oven at 110 to 120 C. for 24 hr. immediately preceding the test.

(*b*) *Wet Condition.*—Specimens to be tested in the wet condition shall be completely immersed in water at room temperature for at least two weeks, and shall be kept in water until immediately preceding the test.

Procedure

7. (*a*) *Elasticity in Flexure.*—For determining elasticity in flexure, the slab shall be set up on the knife-edge bearings, the deflectometer attached, and an initial load of 20 lb. applied. After setting the dial to approximately zero and noting the readings, the load shall be increased by 10-lb. increments and readings of the deflectometer made for each 50 lb. of load. The reading of the dial shall be recorded to the nearest 0.0001 in. The loading shall be continued until failure of the specimen occurs.

(*b*) *Elasticity in Compression.*—For determining elasticity in compression, the compressometer shall be attached to the specimen and then the specimen accurately centered in the testing machine with the spherical bearing block on the top of the specimen. The center of the spherical surface of the bearing block shall lie in the face of the bearing block in contact with the top bearing surface of the specimen. The spherical bearing shall be kept well lubricated to insure accurate adjustment, which should be made by hand under a small initial load. The speed of the moving head of the testing machine during the application of the load shall be not more than 0.05 in. per min.

An initial load of 500 lb. shall be applied and the dial set to zero. Load increments of 5000 lb. each shall be applied thereafter up to approximately one-half of the estimated breaking load of the specimen, stopping the testing machine at each 5000-lb. loading to read the compressometer, the readings being recorded to the nearest 0.00002 in. After taking the reading at the last 5000-lb. load increment, the load shall be gradually released to 500 lb. and the dial again read. The dial shall then be reset to zero if necessary and a second application of the load made as before. The load shall be fully removed after the reading at 500 lb. following the second load application and the specimen removed from the testing machine. The compressometer shall then be removed and reattached with the specimen turned 90 deg. from its original position. A third application of the load shall then be made as before.

Calculations

8. (*a*) *Elasticity in Flexure.*—The modulus of elasticity in flexure shall be calculated by use of a load-deflection diagram on which the deflections shall be plotted against the loads. A straight line shall be drawn through the origin parallel to the proportional part of the curve. The modulus of elasticity shall then be calculated as follows:

$$E = \frac{wl^3}{4\Delta bd^3}$$

where:

E = modulus of elasticity in pounds per square inch,
w = load ordinate at some convenient point on the line through the origin,
Δ = deformation ordinate of load point chosen,
l = length between supporting knife-edges in inches,
b = width of specimen at the center in inches, and
d = thickness of specimen at the center in inches.

(*b*) *Elasticity in Compression.*—The modulus of elasticity in compression shall be calculated by use of a load-deformation diagram on which the deformations shall be plotted against the loads. A straight line shall be drawn through the origin parallel to the proportional part of the curve. The

modulus of elasticity shall be calculated as follows:

$$E = \frac{s}{d} = \frac{P}{A\,d}$$

where:

E = modulus of elasticity in pounds per square inch,
s = unit stress in pounds per square inch,
d = unit deformation at some convenient point on the line through the origin,
P = total load on specimen at point corresponding to d on line through the origin, and
A = area of specimen at center section.

Report

9. The report shall include the following:

(*a*) The individual and averaged modulus of elasticity in pounds per square inch in flexure or compression for each group of specimens. Each individual test shall be reported, and for the modulus of elasticity of the material the average of all tests shall be used except where an individual result varies from the average of its group by more than 25 per cent, in which case such individual result shall be reported as information only.

(*b*) The types and approximate sizes of specimens used,

(*c*) The condition of the specimen when tested, whether wet or dry,

(*d*) The direction of the application of the load relative to the bedding planes or rift of the specimens. When the load has been applied on a line perpendicular to the bedding or rift planes, the result shall be reported as "modulus of elasticity in pounds per square inch perpendicular to the bedding plane or rift." When the load has been applied on a line parallel to the bedding or rift planes, the result shall be reported as "modulus of elasticity in pounds per square inch parallel to the bedding plane or rift."

(*e*) A definite statement as to the manner in which the specimens were prepared and finished, and

(*f*) The type of testing machine used.

Standard Method of

SHEAR TESTING OF NATURAL BUILDING STONE[1]

A.S.T.M. Designation: C 102 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 102; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the shearing strength of natural building stones used for exterior or interior construction or decorative purposes.

Apparatus

2. Either the modified Johnson shear tool or the Dutton punching shear device may be used in conjunction with any standard testing machine of sufficient capacity. A spherical bearing block of sufficient size to cover the upper end of the plunger of the punching shear device shall be used if that apparatus is employed. Details of the two types of apparatus are shown in Figs. 1 and 2, and assembled views with specimens in place are shown in Fig. 3.

Test Specimens

3. (*a*) Samples shall be representative of the material and shall consist of sections cut from apparently sound material, preferably quarry blocks or slabs. The direction of the bedding planes or rift shall be plainly marked on the samples. The sample shall be of sufficient size to allow the preparation of not less than three specimens having the bedding planes or rift running in the proper direction for the kind of test specified, that is, either parallel or perpendicular to the face of the specimen to which pressure is to be applied in the test.

(*b*) Specimens for use in the Johnson shear tool shall be bars 2 by 2 in. in section and not less than 7 in. in length. For the Dutton punching shear device, slabs 1 in. in thickness, 4 in. in width, and not less than 4 in. in length shall be used.

NOTE.—The most convenient form of specimen for the punching shear test is the flat slab obtained when the flexure test is made, the broken pieces of the slab used in the flexure test nearly always being of the proper length while the slab itself was previously cut to 1 in. in thickness and 4 in. in width. The use of these slabs from the flexure test will eliminate the separate preparation of shear test specimens.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, this method was published as tentative from 1931 to 1936. Editorially revised in 1939 and 1942.

(*c*) The specimens shall be cut from the original samples with saws. No hand cutting with chisels or other tools shall be permitted. The load-bearing surfaces shall be finished to as nearly true and parallel planes as possible, grinding wheels or the use of abrasive powders and rubbing plates affording convenient means of obtaining satisfactory surfaces.

the specimen shall be included in the report as information only.

(*b*) When using the Dutton punching device, center lines shall be laid off on one surface of the slab and the thickness of the slab measured to the nearest 0.01 in. at not less than three points approximately equidistant around the circumference of a 2-in. circle centered on the intersection of the two

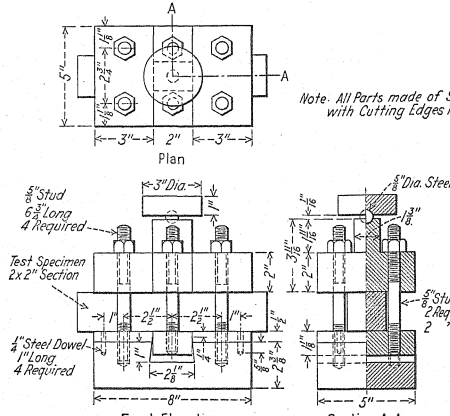


FIG. 1.—Details of Modified Johnson Shear Tool.

Marking Specimens

4. The load-bearing surfaces and the direction of the bedding planes or rift shall be carefully marked on each specimen after finishing.

Measuring Specimens

5. (*a*) For tests with the Johnson shear apparatus the specimen shall be measured to the nearest 0.01 in. at the center section. The area under shearing stress shall be taken as twice the area of this center section. The length of center lines. The width and length of the specimen shall be included in the report as information only.

Conditioning

6. (*a*) *Dry Condition.*—Specimens to be tested in the dry condition shall be dried in an oven at 110 to 120 C. for 24 hr. immediately preceding the test.

(*b*) *Wet Condition.*—Specimens to be tested in the wet condition shall be completely immersed in water at room temperature for at least two weeks,

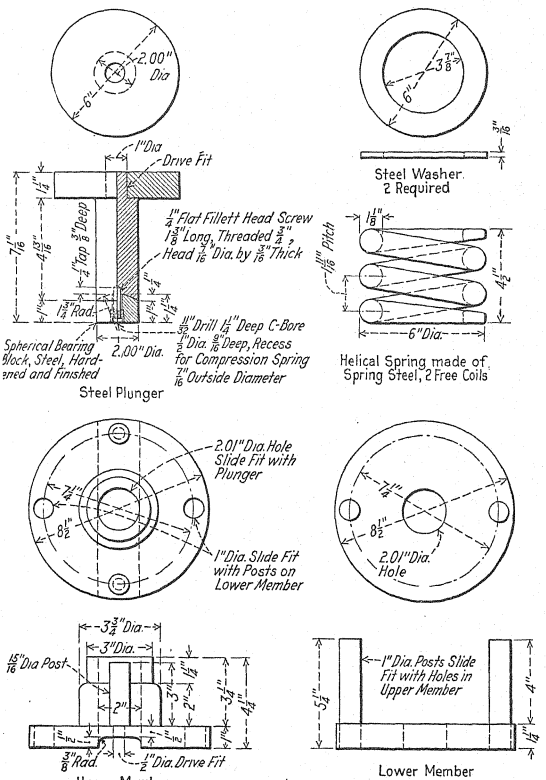

FIG. 2.—Details of Dutton Punching Shear Device.

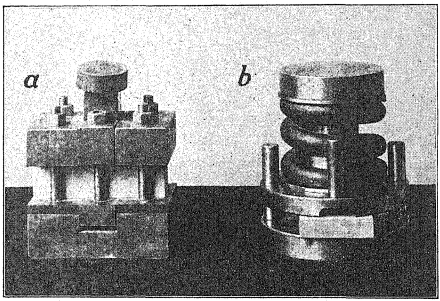


and shall be kept in water until immediately preceding the test.

(*c*) If the broken slabs from the flexure test are to be used, they shall be kept in a desiccator until tested if not tested in shear immediately upon completion of the flexure test.

Procedure

7. (*a*) *Using the Johnson Shear Tool.*—The specimen shall be carefully centered in the shear tool as shown in Fig. 1, and the bolts drawn up tightly. The tool shall then be centered in the testing machine with the center of the spherical block in contact with the center of the top portion of the plunger of the shear tool. The spherical bearing shall be kept well lubricated to insure accurate adjustment which should be made by hand under a small initial load. The speed of the moving head of the testing machine during the application of the load shall be not more than 0.05 in. per min. During the test, the beam of the testing machine shall be kept constantly in a floating position.

(*b*) *Using the Dutton Punching Shear Device.*—The specimen shall be carefully centered between the upper and lower plates of the punching device so that the measured section of the specimen is under the plunger. The upper plate shall be carefully lowered to contact with the specimen. The punching device shall then be centered in the testing machine with the center of the spherical bearing block in contact with the center of the top portion of the plunger of the shear device. The spherical bearing shall be kept well lubricated to insure accurate adjustment which should be made by hand under a small initial load. The speed of the moving head of the testing machine during the application of the load shall be not more than 0.05 in. per min. During the test the beam of the testing machine shall be kept constantly in a floating position.

(*a*) Modified Johnson Shear Tool. (*b*) Dutton Punching Shear Device.
FIG. 3.—Assembled Views of Shear Test Apparatus.

Calculations

8. (*a*) *Using Johnson Shear Tool.*—The shearing strength shall be calculated as follows:

$$S = \frac{W}{2A}$$

where:

S = shearing strength in pounds per square inch,
W = total maximum load in pounds indicated by the testing machine, and
A = area in square inches of the center section of the specimen.

(*b*) *Using the Dutton Punching Device.*—The shearing strength shall be calculated as follows:

$$S = \frac{W_T - W_I}{\pi d T}$$

where:

S = shearing strength in pounds per square inch,
W_T = total maximum load in pounds indicated by the testing machine,
W_I = initial load in pounds required to bring the plunger in contact with the surface of the specimen,
d = diameter in inches of the plunger, and
T = thickness in inches of the specimen.

Report

9. The report shall include the following:

(*a*) The individual and averaged shearing strengths in pounds per square inch for each group of specimens. Each individual test shall be reported, and for the shearing strength of the material the average of all tests shall be used except where an individual result varies from the average of its group by more than 25 per cent, in which case that individual result shall be reported as information only.

(*b*) The type and approximate sizes of specimens used,

(*c*) The condition of the specimen when tested, whether wet or dry,

(*d*) The direction of the application of the load relative to the bedding planes or rift of the specimens. When the load has been applied on a line perpendicular to the bedding or rift planes, the result shall be reported as "shearing strength in pounds per square inch perpendicular to the bedding plane or rift." When the load has been applied on a line parallel to the bedding or rift planes, the result shall be reported as "shearing strength in pounds per square inch parallel to the bedding plane or rift."

(*e*) A definite statement as to the manner in which the specimens were prepared and finished, and

(*f*) The type of shear appliance used.

Standard Methods of

FLEXURE TESTING OF SLATE[1]

MODULUS OF RUPTURE, MODULUS OF ELASTICITY

A.S.T.M. Designation: C 120 – 31

ADOPTED, 1931.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 120; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Due to the unique properties of slate the flexure test is better adapted to use for strength and elasticity determinations than either compression or tension tests. Furthermore, several uses of slate are such that these determinations are of special interest and value, besides furnishing comparative data.

The property of slate termed "grain" causes a slab of the material to break transversely in one direction somewhat more readily than at right angles to this direction. For this reason it is desirable to test the strength and elasticity both parallel and perpendicular to the grain.

In the quarrying of slate, blasting is frequently resorted to and for this reason certain portions of the material may have been unduly strained. Low or erratic strength results on some of the test specimens should be regarded in the light of defective material.

Scope

1. These methods of test cover the procedures for determining the modulus of rupture and modulus of elasticity of slate by means of flexure tests.

MODULUS OF RUPTURE

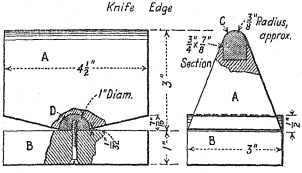
Test Specimens

2. (*a*) *Structural or Electrical Slate.*—Six representative specimens, 12 by 1½ by 1 in. in size, of the particular slate under consideration shall be tested.

(*b*) *Roofing Slate.*—At least six specimens 4 in. in width, 12 in. or more in length, and of thickness equal to that of the slate shingle shall be tested.

Preparation of Specimens

3. (*a*) *Structural or Electrical Slate.*—The slate for the test shall have been split to a thickness of approximately 1¼ in. and then sawed into strips 12 in. in length by 1½ in. in width. Half of these shall be cut with the length parallel to the grain and half with the length perpendicular to the grain (Note 1). The 12 by 1½-in. faces shall then be planed or rubbed down to a thickness of ap-



[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, these methods were published as tentative from 1925 to 1931, being revised in 1927 and 1931. Editorially revised and rearranged in 1939.

proximately 1 in., care being taken to have the finished surfaces as nearly parallel as practicable.

(*b*) *Roofing Slate.*—The specimens shall be sawed from the shingles with the long dimension parallel to the long dimension of the shingle (Note 2) so that no saw cut is nearer than 1 in. to the sheared edge of the shingle. Split faces shall not be refinished.

NOTE 1.—When it is desired to test a finished slab of slate intended for structural or electrical uses, the specimens may be sawed from the sides. Those cut the long way of the slab may be considered to be parallel to the grain and those cut the short way, perpendicular to the grain.

A, B = *Cast Iron Wedges.*
C, D = *Cold-Rolled Steel.*

FIG. 1.—Self-Adjusting Knife-Edge Bearing and Load-Application Device.

NOTE 2.—This gives a specimen parallel to the grain and when broken transversely, the fracture will occur across the grain. Ordinarily, it is not considered necessary to test roofing slate in both directions of the grain.

Conditioning

4. Before testing, the specimens shall be dried in an oven at 110 ± 3 C. for 24 hr.

Measuring Specimens

5. The thickness at the middle shall be measured to the nearest 0.001 in., and the width shall be measured to the nearest 0.01 in.

Procedure

6. The testing machine shall be sensitive to 5 lb. when loaded to 500 lb. The specimen shall be supported flatwise on knife-edges of the type shown in Fig. 1 spaced 10 in. on centers. The load shall be applied through a third knife-edge at the middle of the span at a rate of approximately 100 lb. per min. The breaking load shall be recorded to the nearest 5 lb.

NOTE.—The following method of marking the specimens before testing is recommended:

By means of a try square the middle section and two end sections, 5 in. distant from the center, may be circumscribed. These marks serve as a guide to the operator in properly centering and aligning the specimen in the testing machine.

Calculations

7. The modulus of rupture shall be calculated as follows:

$$R = \frac{3wl}{2bd^2}$$

where:

R = modulus of rupture in pounds per square inch,
w = breaking load in pounds,
l = span length between supporting knife-edges,
b = width of specimen at the center in inches, and
d = thickness of specimen at the center in inches.

Report

8. The average of the specimens cut parallel to the grain from structural or electrical slate, or parallel to the long dimension of the shingle in the case of roofing slate, shall be reported as the modulus of rupture "across the grain." The average of the specimens cut perpendicular to the grain shall be reported as the modulus of rupture "with the grain." In case any specimen shows a value 25 per cent lower than the average of its group, it shall be examined for defects, and if the low value appears to

be due to an imperfection, the average of the other five shall be reported as the modulus of rupture of the group. All determinations shall be reported as information.

MODULUS OF ELASTICITY

Test Specimens

9. The test for modulus of elasticity, when required, is performed in conjunction with the modulus of rupture test described in Sections 2 to 8, and hence the test specimens are of the same type and the measuring and drying operations are the same as specified in Sections 2 to 5.

Procedure

10. The specimen shall be supported and loaded in the same way as for the modulus of rupture determination except that the loading shall be interrupted at suitable intervals for deflection measurements. A deflectometer capable of measuring accurately to 0.001 in. shall be used to obtain the deflections at the middle of the span. For test specimens of structural or electrical slate it will be satisfactory to record the deflections for each 50-lb. increment of load, but for test specimens of roofing slate the deflections shall be recorded for each 20-lb. increment.

NOTE.—It is not ordinarily feasible to set the deflectometer to read zero when there is no load on the specimen. The best practice is to put a small initial load on the specimen, as 10 lb. and set the deflectometer to read zero for this load. Since it is only the slope of the stress-strain curve that is desired, this initial load does not affect the final result.

Calculations

11. The load-deflection readings shall be plotted on cross-section paper to a convenient scale and a straight line drawn to represent, as nearly as possible, the average of the plotted points.[3] If the line does not pass through the zero point, a corrected line shall be drawn through this point parallel to the stress-strain line. The modulus of elasticity, E, shall be calculated from the coordinates of some convenient point on the corrected line by means of the following formula:

$$E = \frac{W'l^3}{4\Delta bd^3}$$

where:

W' = load coordinate of the point,
Δ = deformation ordinate of the point,
l = length of span in inches,
b = width of specimen at the center in inches, and
d = thickness of specimen at the center in inches.

Report

12. In general, the average of the results obtained for specimens prepared with the length parallel to the grain shall be reported as the modulus of elasticity across the grain. Likewise, the average of the results obtained on specimens cut with the length perpendicular to the grain shall be reported as the modulus of elasticity with the grain. In case an individual determination differs by more than 25 per cent from the average of its group, it may be disregarded if there is evidence that the determination was of uncertain value, but all determinations shall be reported as information.

[3] Slate does not show a definite yield point in the stress-strain curve.

Standard Method of Test for

WATER ABSORPTION OF SLATE[1]

A.S.T.M. Designation: C 121 - 31

ADOPTED, 1931.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 121; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

It is often desirable to gain some idea of the porosity of a material in question. Actual determinations of the pore space require the use of rather elaborate and refined equipment as well as considerable precision in carrying out the tests. For comparative purposes the absorption test affords a simple and sufficiently accurate means of obtaining the desired information. As applied to slate this test requires somewhat more care and precision than many other materials because of its dense nature and, consequently, the small quantities to be dealt with. Furthermore, the cleavage of slate—that property which permits it to be split into thin sheets of uniform thickness—must be taken into consideration when this test is made. On this account misleading results are often obtained on cubical specimens due to accidental cleavage cracks in the specimens. The shapes of specimens and larger number of specimens recommended in the following procedure are intended to eliminate to a large extent the inconsistent results which may be obtained on this material.

Scope

1. This method of test covers the procedure for determining the water absorption of slate.

Test Specimens

2. (*a*) The test specimens shall consist of square or rectangular slabs from $\frac{3}{16}$ to $\frac{5}{16}$ in. in thickness and not less than 4 in. on any side.

(*b*) Not less than six specimens shall be prepared from each sample of slate, the sample being considered as any number of pieces selected to represent a definite part or grade of the deposit.

Preparation of Specimens

3. (*a*) The slate shall be split to the required thickness and sawed to size. When the specimens are prepared from shingles no saw cut shall be nearer than 1 in. to the sheared edge of the shingle.

(*b*) The specimens shall be freed from loose particles by scrubbing with a fiber brush and clean water.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, this method was published as tentative from 1925 to 1931, being revised in 1927 and 1931. Editorially revised and rearranged in 1939.

Procedure, Preferred Method

4. (*a*) The specimens shall be dried in a well ventilated oven at 110 ± 3 C. for 24 hr.

(*b*) After drying, the specimens may be cooled in the room for 15 min. and then weighed. When the specimens cannot be weighed immediately after cooling, they should be placed in a desiccator. The weight shall be determined to the nearest 0.01 g.

(*c*) The specimens shall be entirely immersed in distilled water at approximately 20 C. for 48 hr., then removed one at a time, the surface wiped off with a damp cloth, and each specimen immediately weighed to the nearest 0.01 g.

NOTE.—The operator should distinguish between a damp cloth and a wet one. In starting the operation, the towel should be sprinkled lightly. When the surface of the specimen is properly wiped off, it should appear dry.

Procedure, Alternative Method

5. Occasionally it is desirable to obtain results in a shorter period than that required by the procedure described in Section 4. In such cases, the 48-hr. immersion period may be supplanted by an 8-hr. boiling period (Note). In this alternative method the operations shall be the same as described in Section 4 up to that of immersion. Instead of allowing the specimens to soak for 48 hr. they may be placed in an enameled pan or other suitable vessel, covered with water, and boiled for 8 hr. Before the final weighing, the specimens shall be cooled by allowing tap water to flow over them for at least 30 min.

NOTE.—Boiling for 8 hr. has been found to give practically the same saturation as immersion for 48 hr.

Calculations and Report

6. (*a*) The percentage of absorption shall be calculated as follows:

$$\text{Absorption, per cent} = \frac{B - A}{A} \times 100$$

where:

A = weight of the dried specimen, and

B = weight of the specimen after immersion.

(*b*) In general, the average of all the tests shall be reported as the absorption of the slate. Individual determinations which differ by more than 25 per cent from the average of all the determinations may be disregarded when there is evidence that such results are of uncertain value. The absorption shall then be reported as the average of the remaining determinations, but all determinations shall be reported as information.

Standard Definition of

THE TERM SLATE[1]

A.S.T.M. Designation: C 119 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 119; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Slate.—A microgranular crystalline stone derived from argillaceous sediments by regional metamorphism, and characterized by a perfect cleavage entirely independent of original bedding, which cleavage has been induced by pressure within the earth.

NOTE 1.—The essential mineral constituents are white mica (chiefly sericite) and quartz. Prominent accessory constituents are black mica (biotite), chlorite and hematite. Minor accessory constituents are carbonates, magnetite, apatite clay, andalusite, barite, rutile, pyrite, graphite, feldspar, zircon, tourmaline, and carbonaceous matter.

NOTE 2.—Igneous slates because of their rare occurrence and insignificant commercial importance are not covered in this definition.

[1] Under the standardization procedure of the Society, this definition is under the jurisdiction of the A.S.T.M. Committee C-18 on Natural Building Stones and Slate.

[2] Prior to adoption as standard, this definition was published as tentative from 1926 to 1927.

Standard Specifications for

AGGREGATE FOR MASONRY MORTAR[1]

A.S.T.M. Designation: C 144 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 144; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover aggregates for use in masonry mortar.

Material

2. Aggregate for use in masonry mortar shall consist of fine granular material composed of hard, strong, durable mineral particles which are free of injurious amounts of saline, alkaline, organic, or other deleterious substances.

Grading

3. (*a*) Aggregates for use in masonry mortar shall be graded from fine to coarse within the following limits, except as modified in accordance with Paragraphs (*b*) and (*c*):

Sieve Size	Percentages Passing Each Sieve
No. 4 (4760-micron)	100
No. 8 (2380-micron)	95 to 100
No. 16 (1190-micron)	60 to 100
No. 30 (590-micron)	35 to 70
No. 50 (297-micron)	15 to 35
No. 100 (149-micron)	0 to 15

(*b*) The fine aggregate shall be so graded that neither the proportion finer than a No. 16 (1190-micron) sieve and coarser than a No. 30 (590-micron) sieve nor the proportion finer than a No. 30 (590-micron) sieve and coarser than a No. 50 (297-micron) sieve exceeds 50 per cent.

(*c*) The requirements for grading in Paragraphs (*a*) and (*b*) represent the extreme limits which shall determine the suitability of a fine aggregate for use in masonry mortar. The gradation of material from any one source shall be reasonably uniform and shall not be permitted to vary over the extreme range shown in Paragraph (*a*). Fine aggregate from any one source having a variation in fineness modulus greater than plus or minus 0.20 from the fineness modulus of a representative sample submitted by the contractor shall be rejected, or it may be accepted subject to such adjustment in proportions as may be necessary by reason of changes in grading.

NOTE.—For heavy construction employing joints thicker than ½ in. a coarser aggregate may be desirable; for such work a fine aggregate

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M Committee C-12 on Mortars for Unit Masonry.

[2] Prior to adoption as standard, these specifications were published as tentative from 1939 to 1944, being revised in 1942.

conforming to conventional specifications for aggregate for use in concrete and containing not less than 10 per cent of material passing a No. 50 (297-micron) sieve is satisfactory. For unusually thin joints, such as occur for units having cut or ground edges, an aggregate conforming to the requirements of these specifications, but with not less than 95 per cent passing a No. 16 (1190-micron) sieve, should be used.

Deleterious Substances

4. (*a*) The amount of deleterious substances shall not exceed the following:

	Maximum Permissible Percentage by Weight
Coal and lignite	0.25
Clay lumps	1
Shale, alkali, coated grains, soft or flaky particles	1
Other deleterious substances	as specified
Total deleterious substances	3

(*b*) Aggregate subjected to the colorimetric test for organic impurities and producing a color darker than the standard shall be rejected unless it shall pass the mortar strength test as specified in Section 5.

Mortar Strength Test

5. Aggregate shall be of such quality when subjected to the mortar strength test that it shall have a compressive strength at ages of 7 and 28 days of not less than 95 per cent of that developed by a mortar of the same water-cement ratio and consistency made with the same cement and graded Ottawa sand having a fineness modulus of 2.40 ± 0.10.

Methods of Testing

6. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Sieve Analysis.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[3]

(*b*) *Washing Test.*—Standard Method of Test for Amount of Material Finer than No. 200 Sieve in Aggregates (A.S.T.M. Designation: C 117).[3]

(*c*) *Coal and Lignite.*—Standard Method of Test for Coal and Lignite in Sand (A.S.T.M. Designation: C 123).[3]

(*d*) *Clay Lumps.*—Standard Method of Test for Clay Lumps in Aggregates (A.S.T.M. Designation: C 142).[3]

(*e*) *Organic Impurities.*—Standard Method of Test for Organic Impurities in Sands for Concrete (A.S.T.M. Designation: C 40).[3]

(*f*) *Mortar Strength.*—Standard Method of Test for Structural Strength of Fine Aggregate Using Constant Water-Cement-Ratio Mortar (A.S.T.M. Designation: C 87).[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A2.1-1942

Standard Methods of
FIRE TESTS OF BUILDING CONSTRUCTION AND MATERIALS[1]

A.S.T.M. Designation: C 19 – 41

ADOPTED, 1933; REVISED 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 19; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

The performance of walls, columns, floors, and other building members under fire exposure conditions is an item of major importance in securing constructions that are safe, and that are not a menace to neighboring structures nor to the public. Recognition of this is registered in the codes of many authorities, municipal and other. It is important to secure balance of the many units in a single building, and of buildings of like character and use in a community; and also to promote uniformity in requirements of various authorities throughout the country. To do this it is necessary that the fire-resistive properties of materials and assemblies be measured and specified according to a common standard expressed in terms that are applicable alike to a wide variety of materials, situations, and conditions of exposure.

Such a standard is found in the methods that follow. They prescribe a standard exposing fire of controlled extent and severity. Performance is defined as the period of resistance to standard exposure elapsing before the first critical point in behavior is observed. Results are reported in units in which field exposures can be judged and expressed.

The methods may be cited as the "Standard Fire Tests," and the performance or exposure shall be expressed as "2-hr.," "6-hr.," "½-hr.," etc.

When a factor of safety exceeding that inherent in the test conditions is desired, a proportional increase should be made in the specified time-classification period.

Classifications of assemblies involving combustibles in such kind or quantity or so contained as to burn freely during the exposure to the test fire, or continue flaming or ignite after the furnace fire is shut off, shall be designated by the term "combustible" after the period assigned.

---

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-5 on Fire Tests of Materials and Construction.

These methods, of which the present standard represents a revision, were prepared by Sectional Committee A2 on Fire Tests of Materials and Construction, under the joint sponsorship of the National Bureau of Standards, the A.S.A. Fire Protection Group, and the American Society for Testing Materials, functioning under the procedure of the American Standards Association.

[2] Prior to their present adoption as standard, these methods were published as tentative from 1917 to 1918, being revised in 1918. They were adopted in 1918, but withdrawn and republished as tentative from 1926 to 1933, being revised in 1933.

Scope

1. (*a*) These methods of fire tests are applicable to assemblies of masonry units and to composite assemblies of structural materials for buildings, including bearing and other walls and partitions, columns, girders, beams, slabs, and composite slab and beam assemblies for floors and roofs. They are also applicable to other assemblies and structural units that constitute permanent integral parts of a finished building.

(*b*) It is the intent that classifications shall register performance during the period of exposure and shall not be construed as having determined suitability for use after fire exposure.

CONTROL OF FIRE TESTS

Time-Temperature Curve

2. The conduct of fire tests of materials and construction shall be controlled by the standard time-temperature curve shown in Fig. 1. The points on the curve that determine its character are:

1000 F. (538 C.)	at	5 min.
1300 F. (704 C.)	at	10 min.
1550 F. (843 C.)	at	30 min.
1700 F. (927 C.)	at	1 hr.
1850 F. (1010 C.)	at	2 hr.
2000 F. (1093 C.)	at	4 hr.
2300 F. (1260 C.)	at	8 hr. or over

Furnace Temperatures

3. (*a*) The temperature fixed by the curve shall be deemed to be the average temperature obtained from the readings of not less than five thermocouples symmetrically disposed and distributed to show the temperature near all parts of the sample, the thermocouples being enclosed in sealed porcelain tubes $\frac{3}{4}$ in. in outside diameter and $\frac{1}{8}$ in. in wall thickness, or, as an alternative in the case of base metal thermocouples, enclosed in sealed, standard-weight $\frac{1}{2}$-in. black wrought steel or black wrought iron pipe. The exposed length of the pyrometer tube and thermocouple in the furnace chamber shall be not less than 12 in. Other types of protecting tubes or pyrometers may be used that, under test conditions, give the same indications as the above standard within the limit of accuracy that applies for furnace-temperature measurements. For floors and columns, the junction of the thermocouples shall be placed 12 in. away from the exposed face of the sample at the beginning of the test and, during the test, shall not touch the sample as a result of its deflection. In the case of walls and partitions, the thermocouples shall be placed 6 in. away from the exposed face of the sample at the beginning of the test, and shall not touch the sample during the test, in the event of deflection.

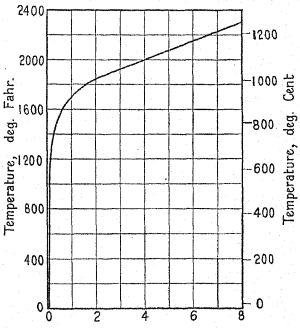


FIG. 1.—Time-Temperature Curve.

(*b*) The temperatures shall be read at intervals not exceeding 5 min. during the first hour, and thereafter the intervals may be increased to not more than 15 min.

(*c*) The accuracy of the furnace control shall be such that the area under the time-temperature curve, obtained by averaging the results from the pyrometer readings, is within 10 per cent of the corresponding area under the standard time-temperature curve shown in Fig. 1

for fire tests of 1 hr. or less duration, within 7.5 per cent for those over 1 hr. and not more than 2 hr., and within 5 per cent for tests exceeding 2 hr. in duration.

Temperatures of Unexposed Surfaces of Floors, Walls, and Partitions

4. (*a*) Temperatures at unexposed surfaces shall be measured with thermocouples or thermometers[3] placed under flexible, oven-dry, felted asbestos pads 6 in. square, 0.4 in. in thickness, and weighing not less than 1.0 nor more than 1.4 lb. per sq. ft. The pads shall be sufficiently soft so that, without breaking, they may be shaped to contact over the whole surface against which they are placed. The wire leads of the thermocouple or the stem of the thermometer shall have an immersion under the pad and be in contact with the unexposed surface for not less than $3\frac{1}{2}$ in. The hot junction of the thermocouple or the bulb of the thermometer shall be placed approximately under the center of the pad. The outside diameter of protecting or insulating tubes, and of thermometer stems, shall be not more than $\frac{5}{16}$ in. The pad shall be held firmly against the surface, and shall fit closely about the thermocouples or thermometer stems Thermometers shall be of the partial-immersion type, with a length of stem, between the end of the bulb and the immersion mark, of 3 in. The wires for the thermocouple in the length covered by the pad shall be not heavier than No. 18 B. & S. gage (0.04 in.) and shall be electrically insulated with heat-resistant and moisture-resistant coatings.

(*b*) Temperature readings shall be taken at not less than five points on the surface, one of which shall be approximately at the center, and four at approximately the centers of the quarter sections. If additional points are used they shall be symmetrically disposed about the center, with no location nearer than $1\frac{1}{2}$ times the thickness of the construction, or nearer than 12 in., to the edges. None shall be located opposite or on top of beams, girders, pilasters, or other structural members.

(*c*) Temperature readings shall be taken at intervals not exceeding 15 min. until a reading exceeding 212 F. (100 C.) has been obtained at any one point. Thereafter the readings may be taken more frequently at the discretion of the testing body, but the intervals need not be less than 5 min.

(*d*) Where the conditions of acceptance place a limitation on the rise of temperature of the unexposed surface, the temperature end point of the fire endurance period shall be determined by the average of the measurements taken at individual points; except that if a temperature rise 30 per cent in excess of the specified limit occurs at any one of these points, the remainder shall be ignored and the fire endurance period judged as ended.

CLASSIFICATION AS DETERMINED BY TEST

Report of Results

5. Results shall be reported in accordance with the performance in the tests prescribed in these specifications. They shall be expressed in time periods of resistance, as for example 4-hr., $\frac{1}{2}$-hr., etc.

TEST STRUCTURES

Test Structures

6. (*a*) The test structure may be located at any place where all the necessary facilities for properly conducting the test are provided.

(*b*) Entire freedom is left to each investigator in the design of the test structure and the nature and use of fuel, provided the test requirements are met.

[3] Under certain conditions it may be unsafe or impracticable to use thermometers.

TEST SAMPLE

Test Sample

7. (*a*) The test sample shall be truly representative of the construction for which classification is desired, as to materials, workmanship, and details such as dimensions of parts, and shall be built under conditions representative of those obtaining as practically applied in building construction and operation. The physical properties of the materials and ingredients used in the test sample shall be determined and recorded.

(*b*) The size and dimensions of the test sample specified herein are intended to apply for rating constructions of dimensions within the usual general range employed in buildings. If the conditions of use limit the construction to smaller dimensions, a proportionate reduction may be made in the dimensions of the samples for a test qualifying them for such restricted use.

CONDUCT OF FIRE TESTS

Fire Endurance Test

8. The fire endurance test on the sample with its applied load, if any, shall be continued until failure occurs, or until it has withstood the test conditions for a period equal to that herein specified in the conditions of acceptance for the given type of construction.

Hose Stream Test

9. (*a*) Where required by the conditions of acceptance, a duplicate sample shall be subjected to a fire exposure test for a period equal to one half of that indicated as the resistance period in the fire endurance test, but not for more than 1 hr., immediately after which the sample shall be subjected to the impact, erosion, and cooling effects of a hose stream directed first at the middle and then at all parts of the exposed face, changes in direction being made slowly.

(*b*) *Exemption.*—The hose stream test shall not be required in the case of indicated in the fire endurance test, of less than 1 hr.

(*c*) *Optional Program.*—The submitter may elect, with the advice and consent of the testing body, to have the hose stream test made on the sample subjected to the fire endurance test and immediately following the expiration of the fire endurance test.

(*d*) *Stream Equipment and Details.*—The stream shall be delivered through 2½-in. hose discharging through a National Standard Playpipe of corresponding size equipped with a 1⅛-in. discharge tip of the standard-taper smooth-bore pattern without shoulder at the orifice. The water pressure and duration of application shall be as prescribed in Table I.

TABLE I.

Resistance Period	Water Pressure at Base of Nozzle, psi.	Duration of Application, min. per 100 sq. ft. exposed area
8 hr. and over	45	6
4 hr. and over if less than 8 hr.	45	5
2 hr. and over if less than 4 hr.	30	2½
1½ hr. and over if less than 2 hr.	30	1½
1 hr. and over if less than 1½ hr.	30	1

(*e*) *Nozzle Distance.*—The nozzle orifice shall be 20 ft. from the center of the exposed surface of the test sample if the nozzle is so located that when directed at the center its axis is normal to the surface of the test sample. If otherwise located, its distance from the center shall be less than 20 ft. by an amount equal to 1 ft. for each 10 deg. of deviation from the normal.

Time of Testing

10. The material or construction shall not be tested until a large proportion of its final strength has been attained, and,

has been given off; this will usually require about 30 days time under favorable drying conditions. Artificial drying at temperatures not injurious to the material or construction to be tested may be used.

TESTS OF BEARING WALLS AND PARTITIONS

Size of Sample

11. The area exposed to fire shall be not less than 100 sq. ft., with neither dimension less than 9 ft. The test specimen shall not be restrained on its vertical edges.

Loading

12. During the fire endurance and fire and hose stream tests the construction shall be loaded in a manner calculated to develop theoretically, as nearly as practicable, the working stresses contemplated by the design.

Conditions of Acceptance

13. The test shall not be regarded as successful unless the following conditions are met:

(*a*) The wall or partition shall have sustained the applied load during the fire endurance test without passage of flame or gases hot enough to ignite cotton waste, for a period equal to that for which classification is desired.

(*b*) The wall or partition shall have sustained the applied load during the fire and hose stream test as specified in Section 9, without passage of flame, of gases hot enough to ignite cotton waste, or of the hose stream, and after cooling but within 72 hr. after its completion shall sustain a total load equal to the dead load plus twice the superimposed load specified above.

(*c*) Transmission of heat through the wall or partition during the fire endurance test shall not have been such as to raise the temperature on its unexposed surface more than 250 F. (139 C.) above its initial temperature.

TESTS OF NONBEARING WALLS AND PARTITIONS

Size of Sample

14. The area exposed to fire shall be not less than 100 sq. ft., with neither dimension less than 9 ft. The test specimen shall be restrained on all four edges.

Conditions of Acceptance

15. The test shall not be regarded as successful unless the following conditions are met:

(*a*) The wall or partition shall have withstood the fire endurance test without passage of flame or gases hot enough to ignite cotton waste, for a period equal to that for which classification is desired.

(*b*) The wall or partition shall have withstood the fire and hose stream test as specified in Section 9, without passage of flame, of gases hot enough to ignite cotton waste, or of the hose stream.

(*c*) Transmission of heat through the wall or partition during the fire endurance test shall not have been such as to raise the temperature on its unexposed surface more than 250 F. (139 C.) above its initial temperature.

TESTS OF COLUMNS

Size of Sample

16. The length of the column exposed to fire shall, when practicable, approximate the maximum clear length contemplated by the design, and for building columns shall be not less than 9 ft. The contemplated details of connections, and their protection if any, shall be applied according to the methods of acceptable field practice.

Loading

17. (*a*) During the fire endurance test the column shall be exposed to fire on all sides and shall be loaded in a manner calculated to develop theoretically, as nearly as practicable, the working stresses contemplated by the design. Provision shall be made for transmitting the load to the exposed portion of the column without unduly increasing the effective column length.

(*b*) If the submitter and the testing body jointly so decide, the column may be subjected to $1\frac{3}{4}$ times its designed working load before the fire endurance test is undertaken. The fact that such a test has been made shall not be construed as having had a deleterious effect on the fire endurance test performance.

Condition of Acceptance

18. The test shall not be regarded as successful unless the column shall have sustained the applied load during the fire endurance test for a period equal to that for which classification is desired.

TESTS OF FLOORS AND ROOFS

(The following contemplates application of fire exposure to the under side of constructions.)

Size of Sample

19. The area exposed to fire shall be not less than 180 sq. ft., with neither dimension less than 12 ft. Beams or girders, if a part of the construction under test, shall lie within the combustion chamber and have a clearance of not less than 8 in. from its walls.

Loading

20. During the fire endurance and fire and hose stream tests the construction shall be loaded in a manner calculated to develop theoretically, as nearly as practicable, the working stresses in each member contemplated by the design.

Conditions of Acceptance

21. The test shall not be regarded as successful unless the following conditions are met:

(*a*) The construction shall have sustained the applied load during the fire endurance test without passage of flame or gases hot enough to ignite cotton waste, for a period equal to that for which classification is desired.

(*b*) The construction shall have sustained the applied load during the fire and hose stream test as specified in Section 9, without passage of flame, of gases hot enough to ignite cotton waste, or of the hose stream, and, after cooling but within 72 hr. after its completion, shall sustain a total load equal to the dead load plus twice the superimposed load specified above.

(*c*) Transmission of heat through the construction during the fire endurance test shall not have been such as to raise the temperature on its unexposed surface more than 250 F. (139 C.) above its initial temperature.

TESTS OF PROTECTION FOR COMBUSTIBLE FRAMING, OR FOR COMBUSTIBLE FACINGS ON THE UNEXPOSED SIDE OF WALLS, PARTITIONS, AND FLOORS

Character of Sample

22. Test panels carrying wall, partition, or floor protection shall be finished with the protections which are the subject of the test, except that where the finish on the unexposed side is not the subject of the test and is not specifically indicated, the testing authority shall apply a finish judged suitable for the purpose. In case a floor construction, as installed for actual use, is to have no finish on the unexposed side, it shall be so tested.

Size of Sample

23. The area exposed to fire shall be, for tests of wall and partition protection, not less than 100 sq. ft. with neither dimension less than 9 ft.; for tests of floor protection, not less than 180 sq. ft. with neither dimension less than 12 ft.

Conditions of Acceptance

24. The test shall not be regarded as successful unless the following conditions are met:

(*a*) The protection shall have withstood the fire endurance test, without ignition of the materials protected, for a period equal to that for which classification is desired.

(*b*) Transmission of heat through the protection during the fire endurance test shall not have been such as to raise the temperatures at its contact with the protected structural members or facings of the test panel more than 250 F. (139 C.) above the initial temperatures at these points, except that for members closely embedded on three sides in masonry, concrete, or other incombustible materials the permissible temperature rise may be 325 F. (181 C.).

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A2.2-1942

Standard Methods of
FIRE TESTS OF DOOR ASSEMBLIES[1]

A.S.T.M. Designation: C 152 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 152; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These methods of fire test are applicable to door assemblies, of various materials and of various types of construction, for installation as wall opening protectives to serve against the passage of fire, heat, fumes, or smoke.[3]

(*b*) It is the intent that classifications shall register performance during the period of exposure and shall not be construed as having determined suitability for use after exposure to either fire, or fire and hose stream.

(*c*) These methods do not establish ratings, or standards of performance for different uses, as these depend upon service requirements and are under the control of various regulatory bodies.

CONTROL OF FIRE TESTS

Time-Temperature Curve

2. The conduct of fire tests of materials and construction shall be controlled by the standard time-temperature curve shown in Fig. 1. The points on the curve that determine its character are:

1000 F. (538 C.)	at 5 min.
1300 F. (704 C.)	at 10 min.
1550 F. (843 C.)	at 30 min.
1700 F. (927 C.)	at 1 hr.
1850 F. (1010 C.)	at 2 hr.
2000 F. (1093 C.)	at 4 hr.
2300 F. (1260 C.)	at 8 hr. or over

Furnace Temperatures

3. (*a*) The temperature fixed by the curve shall be deemed to be the average temperature obtained from the readings of not less than five thermocouples symmetrically disposed and distributed to show the temperature near all parts of the test assembly, the thermocouples being enclosed in sealed porcelain tubes $\frac{3}{4}$ in. in outside diameter and $\frac{1}{8}$ in. in wall thickness, or, in the case of base metal thermocouples, enclosed in sealed, standard-weight $\frac{1}{2}$-in. wrought steel pipe. The exposed length of the pyrometer tube and couple in the furnace chamber shall be not less than 12 in. Other types of protecting tubes or pyrometers may be used that, under test conditions, give the same indications as the above standard within the limit of accuracy that applies for furnace-temperature

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-5 on Fire Tests of Materials and Construction.

[2] Prior to adoption as standard, these methods were published as tentative from 1940 to 1941.

[3] The committee is giving consideration to the subject of smoke generation and the creation and spread of dangerous fumes, which upon completion will result in subsequent revision of these methods.

measurements. The junction of the thermocouples shall be placed 4 to 6 in. away from the exposed face of the test assembly at the beginning of the test, and during the test shall not touch the assembly as a result of its deflection.

(*b*) The temperatures shall be read at intervals not exceeding 5 min. during the first hour, and thereafter at intervals not exceeding 15 min.

(*c*) The accuracy of the furnace control shall be such that the area under the time-temperature curve, obtained by averaging the results from the

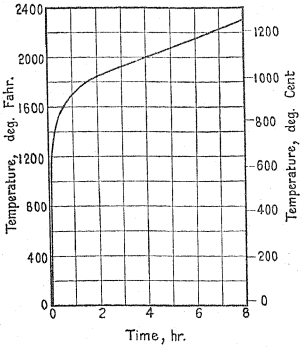

FIG. 1.—Time-Temperature Curve.

pyrometer readings, is within 10 per cent of the corresponding area under the standard time-temperature curve shown in Fig. 1 for fire tests of 1 hr. or less duration, within 7.5 per cent for those over 1 hr. and not more than 2 hr., and within 5 per cent for tests exceeding 2 hr. in duration.

Temperature of Unexposed Surfaces of Doors

4. (*a*) Temperatures at unexposed surfaces shall be measured with thermocouples or thermometers placed under flexible, oven-dry, felted asbestos pads 6 in. square, 0.4 in. in thickness, and weighing not less than 1.0 nor more than 1.4 lb. per sq. ft. The pads shall be sufficiently soft that, without breaking, they may be shaped to contact over the whole surface against which they are placed. The wire leads of the thermocouple or the stem of the thermometer shall have an immersion under the pad and be in contact with the unexposed surface for not less than $3\frac{1}{2}$ in. The hot junction of the thermocouple or the bulb of the thermometer shall be placed approximately under the center of the pad. The outside diameter of protecting or insulating tubes, and of thermometer stems, shall be not more than $\frac{5}{16}$ in. The pad shall be held firmly against the surface, and shall fit closely about the thermocouples or thermometer stems. Thermometers shall be of the partial-immersion type, with a length of stem, between the end of the bulb and the immersion mark, of 3 in. The wires of the thermocouple in the length covered by the pad shall be not heavier than No. 18 B. & S. gage (0.04 in.) and shall be electrically insulated with heat-resistant and moisture-resistant coatings.

(*b*) Temperature readings shall be taken at not less than three points, one located at the middle of the unexposed surface of the test assembly and one each at the mid-points of the upper and lower halves of the assembly. If the construction is not uniform, or if, in the opinion of the testing authority, temperature measurements at other locations are necessary to give a true indication of performance, the thermocouples shall be symmetrically disposed to give results representative of the different constructions, and preferably with no location nearer than 12 in. to the edges of the test assembly.

(*c*) Temperature readings on the unexposed surfaces shall be taken at the same intervals as specified for furnace temperatures.

(*d*) If a temperature end point of the rating period is specified, it shall be determined by the average of the measurements taken at individual points representing the least resistant construction; except that if a temperature rise 30 per cent in excess of the limit established by the regulatory body for whom the test is made occurs at any one of these points, the remainder shall be ignored and the fire endurance period judged as ended.

NOTE.—At the discretion of the testing authority, additional temperature measurements may be taken on, or near the unexposed surface.

TEST STRUCTURES

Test Structures

5. (*a*) The test structure may be located at any place where all the necessary facilities for properly conducting the test are provided.

(*b*) Entire freedom is left to each testing authority in the design and location of the test structure and the nature and use of fuel, provided the test requirements are met.

TEST ASSEMBLIES

Test Assemblies

6. (*a*) The test assembly shall be truly representative as to material, details (installation, hardware trim, and finish), and workmanship of the construction for which classification is desired. A record of materials and construction details, adequate for identification, shall be made.

(*b*) The test assembly shall consist of the door or doors, together with the necessary framing and appurtenances, installed in a single opening on one or both sides of a common wall.

Size of Test Assembly

7. The classification or rating derived from the test assembly shall be considered to apply to doors of similar design and construction, smaller in dimension and in area, or whose area does not exceed that of the test assembly by more than 25 per cent.

Mounting of Test Assembly

8. (*a*) Swinging doors shall be mounted so as to open into the furnace chamber. Sliding and rolling doors, unless of the flush-mounted type, shall be mounted on the fire side of the wall. Clearances of swinging doors of hollow metal or kalamein types shall conform to good practice,[4] but shall not be less than $\frac{3}{32}$ in. between the door and hinge and lock jambs, $\frac{1}{16}$ in. at the top, and $\frac{3}{16}$ in. at the bottom.

(*b*) Minimum clearances for swinging wood doors shall be $\frac{1}{16}$ in. at the sides and top, and $\frac{3}{16}$ in. at the bottom.

(*c*) If special tightness against the passage of smoke is desired, or if other clearances are used for any reason, the actual clearances shall be reported in the classification of the test assembly.

(*d*) Sliding and rolling doors of any type shall fit well against wall surfaces or in guides, but retaining methods shall allow free and easy movement of the door from any position.

CONDUCT OF FIRE TESTS

Fire Test

9. (*a*) During the fire test the pressure within the furnace shall be maintained as nearly equal to the outside atmospheric pressure as possible.

(*b*) The fire test on the test assembly shall be continued until failure occurs, or the limit of resistance specified by the submitter has been met.

[4] Hollow Metal Single-Acting Swing Doors, Frames, and Trim, Dept. of Commerce Simplified Practice Recommendation R82-28, and Kalamein Single-Acting Swing Doors, Frames, and Trim, Dept. of Commerce Simplified Practice Recommendation R83-28.

Hose Stream Test

10. (*a*) Unless the optional program of the following Paragraph (*c*) is specified, a duplicate test assembly shall be subjected to a fire exposure test for a period equal to one half of the fire resistance period in the fire endurance test, but not for more than 1 hr., immediately after which the test assembly shall be subjected to the impact, erosion, and cooling effects of a hose stream directed first at the middle and then at all parts of the exposed face, changes in direction being made slowly.

(*b*) *Exemption.*—The hose stream test shall not be required in the case of the opening protective having a resistance period, indicated in the fire resistance test, of less than 1 hr.

(*c*) *Optional Program.*—When the test assembly is tested for a desired time limit of fire resistance, the submitter may elect, with the advice and consent of the testing authority, to have the hose stream test made on the assembly subjected to the fire resistance test and immediately following the expiration of the fire resistance test.

(*d*) *Stream Equipment and Details.*—The stream shall be delivered through $2\frac{1}{2}$-in. hose discharging through a National Standard Playpipe of corresponding size equipped with a $1\frac{1}{8}$-in. discharge tip of the standard-taper smooth-bore pattern without shoulder at the orifice. The water pressure and duration of application shall be as prescribed in Table I.

TABLE I.

Resistance Period	Water Pressure at Base of Nozzle, psi.	Duration of Application, min. per 100 sq. ft. exposed area[a]
4 hr. and over	45	5
2 hr. and over, if less than 4 hr.	30	$2\frac{1}{2}$
1 hr. and over, if less than 2 hr.	30	$1\frac{1}{2}$
Less than 1 hr. (if desired)	30	1

[a] A 1-min. application of the hose stream shall be the minimum.

(*e*) *Nozzle Distance.*—The nozzle orifice shall be 20 ft. from the center of the exposed surface of the test assembly if the nozzle is so located that when directed at the center its axis is normal to the surface of the test assembly. If otherwise located, its distance from the center shall be less than 20 ft. by an amount equal to 1 ft. for each 10 deg. of deviation from the normal.

Time of Testing

11. Masonry settings shall be allowed to dry for at least 3 days before tests are made.

CONDITIONS OF ACCEPTANCE

Heat Insulation

12. The testing authority shall record and include in the test report, the temperature measurements taken within the furnace and on the unexposed side of the test assembly as specified in Sections 3 (*a*) and (*b*), and 4 (*a*) to (*d*). Observations of features of the test having a bearing upon the performance of the test assembly shall also be made a part of the report, including passage or production of fumes and smoke.

Fire Resistance

13. The fire resistance test shall not be regarded as successful unless the following conditions are met:

(*a*) The test assembly shall have remained securely in the opening during the fire exposure period and, if required, during the hose stream test. When the test assembly comprises two doors located one on each face of a common wall, the test conditions are met when the door on the unexposed side remains securely in the opening, irrespective of the condition of the door on the fire side.

(*b*) The test assembly shall have withstood the fire endurance and hose stream test, except that small portions

of glass dislodged by the hose stream shall not be considered a weakness, without developing openings anywhere through the assembly, or openings markedly in excess of the initial clearances at the outside or meeting edges.

(*c*) If a transmitted temperature end point is specified, it shall be considered as a condition of acceptance.

Standard Methods of

SAMPLING AND MIXING THERMAL INSULATING CEMENT[1]

A.S.T.M. Designation: C 163 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 163; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover the procedures for sampling thermal insulating cement and for mixing the cement for preparation of specimens for use in all tests on the cement.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Mixing Surface or Pan.*—A nonabsorbent and corrosion-resistant surface or shallow pan approximately 3 ft. square.

(*b*) *Trowel.*—A 16-in. rectangular plasterer's trowel.

(*c*) *Scales.*—A pair of scales accurate to within 0.5 oz.

(*d*) *Water Container.*—A container suitable for holding approximately 2 gal. of water.

Mixing Water

3. The mixing water shall be equal in quality to that used for domestic purposes.

Sampling

4. At least 3 per cent of the packages comprising any one shipment shall be tested. They shall be systematically selected so as to be representative of all parts of the shipment. Each package shall be sampled by removing approximately $\frac{1}{4}$ lb. from the top and $\frac{1}{4}$ lb. from the center. The composite of all samples thus selected shall then be thoroughly mixed and quartered until the sample is of the desired size.

Procedure for Mixing

5. (*a*) The sample of dry cement shall be weighed and placed upon a smooth, nonabsorbent and corrosion-resistant surface.

(*b*) A crater shall be formed in the center of the dry cement and the mixing water shall be placed therein. The amount of mixing water used shall conform to the exact proportions recommended by the manufacturer of the cement.

(*c*) The material on the outer edge shall be turned into the crater by means of the plasterer's trowel.

(*d*) After the water has been ab-

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-16 on Thermal Insulating Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1941 to 1944.

sorbed by the cement or has remained in contact therewith for the period of time recommended by the manufacturer, the trowel shall be rapidly drawn over the cement by alternately applying and releasing pressure on its trailing edge.

(*e*) After three such passes of the trowel across the cement, it shall be gathered in at the edges and turned over with the trowel.

(*f*) The cycle described in Paragraphs (*d*) and (*e*) shall be repeated either until uniformity and optimum plasticity have been obtained or as specified by the manufacturer.

(*g*) The cement shall be molded immediately after mixing or after the lapse of such period of time as may be recommended by the manufacturer.

Standard Method of Test for

BULK DENSITY OF THERMAL INSULATING CEMENT[1]

A.S.T.M. Designation: C 164 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 164; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for determining the bulk density of thermal insulating cement to permit the calculation of the necessary storage space for a given quantity of cement in packages as received.

Definition

2. The bulk density of an insulating cement is the package volume in cubic feet for 100 lb. of packaged cement.

Apparatus

3. The apparatus shall consist of the following:

(*a*) *Scales.*—A pair of scales accurate to within 1 oz.

(*b*) *Rule or Tape.*—An ordinary folding 6-ft. rule or a steel tape accurate to within plus or minus $\frac{1}{16}$ in.

(*c*) *Square.*—A carpenter's square having the blade (the broader, longer leg) extended to a length of at least 36 in.

Procedure

4. (*a*) Twelve packages shall be systematically selected so as to be representative of all parts of the shipment or stock to be tested. The packages may be weighed separately or in groups or they may be all weighed at one time, depending upon the capacity of the available scales. The twelve packages shall then be stacked horizontally in a corner against two walls in a single row three packages high. If the cement is packed in sacks, the tied mouths of the sacks shall be placed alternately against the wall and away from it. At least three measurements of the width, three of the height, and two of the length of the stack shall be made in accordance with the procedure described in the following Paragraphs (*b*) to (*d*). All dimensions shall be expressed in feet.

(*b*) *Width.*—At each of three positions equally spaced along the length of the stack, the tongue (the shorter, narrower arm) of the modified carpenter's square shall be placed on the floor perpendicular to the face of the stack with the extended blade perpendicular to the floor and touching the face of the stack. The shortest distance from the inner edge of the blade to the wall behind the stack shall be measured with the rule or tape. The average of these three measurements shall be taken as the width of the stack.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-16 on Thermal Insulating Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1941 to 1944.

(*c*) *Height.*—At each of three positions equally spaced along the length of the stack, the tongue of the modified carpenter's square shall be placed against the wall above the top of the stack and perpendicular to the floor with the extended blade perpendicular to the wall and touching the top of the stack. The vertical distance from the lower edge of the blade to the floor shall be measured. The average of these three measurements shall be taken as the height of the stack.

(*d*) *Length.*—At each of two positions one fourth of the width of the stack from the front and rear faces of the stack, the tongue of the modified carpenter's square shall be placed on the floor parallel to the nearest wall against which the stack is placed and with the extended blade perpendicular to the floor and touching the end of the stack. The shortest distance from the inner edge of the blade to the wall at the opposite end of the stack shall be measured. The average of these two measurements shall be taken as the length of the stack.

Calculation

5. The bulk density in cubic feet per 100 lb. shall be calculated as follows:

$$\text{Bulk density} = \frac{w \times h \times l}{M} \times 100$$

where:

w = average width of stack in feet,
h = average height of stack in feet,
l = average length of stack in feet, and
M = gross weight of stack in pounds.

Standard Methods of Test for

THICKNESS AND DENSITY OF BLANKET TYPE THERMAL INSULATING MATERIALS[1]

A.S.T.M. Designation: C 167 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 167; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover the procedures for determining the thickness and density of flexible, felted or woven thermal insulating blankets, rolls, or batts, with or without reinforcement, composed of fibrous materials.

Apparatus

2. The apparatus for measuring thickness of the test specimen shall be a depth gage of the type shown in Fig. 1.

Test Specimen

3. (*a*) The size of the test specimen shall not be limited, but the specimen shall be of sufficient area to be representative of the lot or shipment in question.

(*b*) In case of reinforced blanket insulations, the reinforcing material, regardless of its nature, shall not be removed when making thickness measurements. However, in case of high-rib lath reinforcement, the thickness measurement shall be made between ribs or, where this is not practical, the thickness of the rib lath shall be deducted from the total thickness as measured with the depth gage.

Procedure

4. (*a*) *Thickness Measurements.*—The test specimen shall be ruled off into ten approximately square and equal areas and a thickness measurement taken at the center of each area. In making the thickness measurements the test specimen shall be placed on a flat surface and the penetrating pin of the depth gage shall be forced downward through the specimen, perpendicular to the flat surface. When the point of the pin touches the flat surface, the sliding disk shall be lowered to the point of contact with the top surface of the specimen. The gage shall be withdrawn and the distance from the point of the pin to the sliding disk measured within an accuracy of plus or minus $\frac{1}{16}$ in.

(*b*) *Weight and Dimensional Measurements.*—The entire test specimen used for the thickness measurements shall be weighed within an accuracy of plus or minus 0.5 per cent, and the length and width of the specimen shall be measured within an accuracy of plus or minus 0.5 per cent.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-16 on Thermal Insulating Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1941 to 1944.

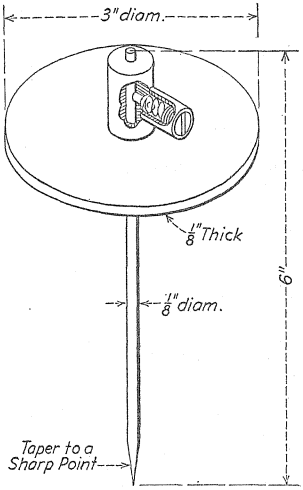

FIG. 1.—Depth Gage for Thickness Measurements.

Calculations

5. (*a*) *Thickness.*—The average of the ten thickness measurements made in accordance with Section 4 (*a*) shall be taken as the "thickness, as-received" of the test specimen.

(*b*) *Density.*—The "density, as-received" and the "density, at specified thickness" shall be calculated as follows:

$$\text{"Density, as received," lb. per cu. ft.} = \frac{W \times 1728}{A \times B \times C_1}$$

$$\text{"Density, at specified thickness," lb. per cu. ft.} = \frac{W \times 1728}{A \times B \times C_2}$$

where:

W = weight of test specimen in pounds,
A = length of specimen in inches,
B = width of specimen in inches,
C_1 = "thickness, as-received," and
C_2 = thickness specified on ordering or designating the material.

Report

6. The report shall include the following:

(*1*) Average, maximum, and minimum values of "thickness, as-received," expressed in inches.

(*2*) "Density, as-received," expressed in pounds per cubic foot.

(*3*) "Density, at specified thickness" expressed in pounds per cubic foot.

Standard Definitions of

TERMS RELATING TO THERMAL INSULATING MATERIALS[1]

A.S.T.M. Designation: C 168 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 168; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Preformed Thermal Insulating Block.—A rigid or semirigid thermal insulating material, either flat or segmental, for application as received, and excluding brick of the 9-in. series.

Thermal Insulating Cement.—A prepared material which, when mixed with a suitable proportion of water, applied as a plastic mass, and dried in place, affords a substantial resistance to heat transmission.

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-16 on Thermal Insulating Materials.

[2] Prior to adoption as standard, these definitions were published as tentative from 1941 to 1944.

Standard Specifications for

REFRACTORIES FOR HEAVY DUTY STATIONARY BOILER SERVICE[1]

A.S.T.M. Designation: C 64 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 64; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) The purpose of these specifications is the selection of fireclay refractories for heavy duty boiler furnaces in which the temperature of the combustion chamber is continuously, or a significant portion of the time, above 2400 F. (1315 C.). They may not apply to special conditions sometimes encountered in high-power utility boilers.

(*b*) These specifications are intended to cover only burned products made from fire clay by the usual processes of manufacture, and are not intended to include products other than those regularly sold as fireclay brick.

Zones of Highest Temperatures

2. (*a*) The refractories to be used in the zones of highest temperatures, such as sidewalls, arches, doors, and jambs, shall be high heat duty or super duty fireclay brick. The conditions to be encountered in the particular installation should be carefully considered so as properly to select from the following classification (Paragraphs (*b*) to (*e*)) the type or types of refractories best suited for the service. Unless type *B*, *C*, or *D* is definitely specified, there shall be supplied for this section of the specifications, type *A*, which is designed for average boiler furnace conditions.

(*b*) *Average Boiler Furnace Conditions.*—In the case of average heavy duty boiler furnace conditions, the refractories shall conform to the requirements for type *A* (Section 6(*a*)).

(*c*) *Moderately Severe Conditions of Spalling.*—When moderately severe conditions of spalling are to be encountered, the refractories shall conform to the requirements for type *B* (Section 6(*b*)).

(*d*) *Moderately Severe Conditions of Slagging.*—When moderately severe con-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] These specifications together with the Standard Specifications for Refractories for Moderate Duty Stationary Boiler Service (C 153 - 41) replace the former Standard Specifications for Fireclay Brick for Stationary Boiler Service (C 64 - 39). These specifications comprise a revision of the requirements for heavy duty refractories formerly contained in Standard Specifications C 64 - 39.

Prior to their present adoption as standard, these specifications were published as tentative from 1927 to 1928. They were adopted in 1928, published as standard from 1928 to 1934, but withdrawn in 1934 and republished as tentative from 1934 to 1936. They were again adopted in 1936, published as standard from 1936 to 1940, being revised in 1939, and again withdrawn and republished as tentative from 1940 to 1941. Editorially revised in 1942.

ditions of slagging are to be encountered, and provided the spalling condition is not too severe, the refractories shall conform to the requirements for type *C* (Section 6 (*c*)).

(*e*) *Extremely Severe Conditions of Spalling or Slagging.*—When extremely severe conditions of spalling or slagging are to be encountered, and especially when both may occur to an unusual extent, the use of super duty fireclay refractories may be justified. When specified, they shall conform to the requirements for type *D* (Section 6 (*d*)).

Division Walls Heated on Both Sides

3. Depending upon the particular conditions to be encountered, the refractories used in constructing the division walls shall be high heat duty or super duty fireclay brick. Unless the super duty fireclay brick, type *D* (Section 6 (*d*)) is definitely specified, there shall be supplied for this section of the specifications the high heat duty fireclay brick, type *E* (Section 6 (*e*)).

Zones of Lower Temperatures

4. This section of the specifications pertains to refractories to be used in backing up the brick in the zones of highest temperatures and for walls of the second and third passes. The service conditions to which such brick are subjected vary with the size and type of boiler, thickness of wall, degree of insulation, draft conditions, and the actual position in the furnace. Leaky baffles may sometimes cause the brick beyond the first tube bank to be subjected to higher temperatures than would normally be present. Depending upon the particular conditions, and upon the margin of safety desired, the brick selected shall be high, intermediate, or low heat duty fireclay brick as specified by type *A*, *F*, or *G*, respectively. Unless type *A* or *G* is definitely specified for this section of the specifications, there shall be supplied the intermediate heat duty brick, type *F* (Section 6 (*f*)).

REQUIREMENTS FOR THE VARIOUS TYPES OF REFRACTORIES

Size and Warpage

5. The following permissible variations in size and warpage shall apply to each type of refractory listed in Section 6:

(*a*) *Size.*—When tested in accordance with the Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134) of the American Society for Testing Materials,[3] the standard 9-in. fireclay brick shall not show a size variation of more than plus or minus 2 per cent. Tile or shapes shall not show a size variation of more than plus or minus 2 per cent on dimensions of 4 in. or over, and plus or minus 3 per cent on dimensions smaller than 4 in.

(*b*) *Warpage.*—Ninety-five per cent of the shapes shall not show a warpage greater than 1 per cent of the diagonal used in making the measurement.

Test Requirements

6. (*a*) ***Type A.***—Type *A* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31–32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] See the Classification of Fireclay Refractories (A.S.T.M. Designation: C 27), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

show a contraction of more than 1.5 per cent.

Spalling.—When subjected to the panel spalling test (preheated at 2910 F., 1600 C.), the brick shall not show a loss greater than 15 per cent.

(*b*) ***Type B.***—Type *B* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31-32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

Spalling.—When subjected to the panel spalling test (preheated at 2910 F., 1600 C.), the brick shall not show a loss greater than 10 per cent.

(*c*) ***Type C.***—Type *C* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31-32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

Water Absorption.—Because *two* varieties of clay refractories can be supplied to conform to the requirements for refractoriness as given above, each type shall conform to a specified maximum water absorption. The brick intended to conform to the specified P.C.E. shall have a water absorption of not more than 10 per cent. Brick which are supplied to conform to the load test requirement shall have a water absorption of not more than 18 per cent.

(*d*) ***Type D.***—Type *D* shall be a super duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 33.

Permanent Linear Shrinkage.—When tested in accordance with schedule C (2910 F., 1600 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1 per cent.

Spalling.—When subjected to the panel spalling test (preheated at 3000 F., 1650 C.), the brick shall not show a loss greater than 4 per cent.

(*e*) ***Type E.***—Type *E* shall be a high heat duty[4] fireclay brick having the following characteristics:

Refractoriness.—*Two* varieties of clay refractories are available for this class: Brick which shall show a deformation of not more than 6 per cent in the 2460 F. (1350 C.) load test and shall have a pyrometric cone equivalent not lower than cone No. 31-32; *or* brick which shall show a deformation of not more than 1.5 per cent in the 2460 F. (1350 C.) load test.

(*f*) ***Type F.***—Type *F* shall be an intermediate heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 29, *or* not more than 3 per cent deformation in the 2460 F. (1350 C.) load test.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 500 psi.

(*g*) ***Type G.***—Type *G* shall be a low heat duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 19.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 500 psi.

Retests

7. Because of variables resulting from sampling and the lack of perfect reproducibility in tests conducted by different laboratories, resampling and retesting may be carried out when requested by either the purchaser or the manufacturer. This may apply in instances where the first test result does not conform to the limits prescribed in these specifications. The final result to be used for each test shall be the average of the original and the retest figures.

NOTE.—Retest provisions for variation in size and water absorption are provided for in those test methods.

Methods of Testing

8. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Size.*—Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134).[3]

(*b*) *Warpage.*—Method of Test for Warpage of Refractory Brick and Tile (A.S.T.M. Designation: C 154).[3]

(*c*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*d*) *Load Test* (2460 F., 1350 C.).—Schedule No. 2 of the Method of Testing Fireclay Refractories Under Load at High Temperatures (A.S.T.M. Designation: C 16).[3]

(*e*) *Permanent Linear Shrinkage for High Heat Duty Brick* (2550 F., 1400 C.).—Schedule B of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*f*) *Permanent Linear Shrinkage for Super Duty Brick* (2910 F., 1600 C.).—Schedule C of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*g*) *Panel Spalling Test for High Heat Duty Brick* (2910 F., 1600 C.).—Method of Panel Test for Resistance to Thermal and Structural Spalling of High Heat Duty Fireclay Brick (A.S.T.M. Designation: C 107).[3]

(*h*) *Panel Spalling Test for Super Duty Brick* (3000 F., 1650 C.).—Method of Panel Test for Resistance to Thermal and Structural Spalling of Super Duty Fireclay Brick (A.S.T.M. Designation: C 122).[3]

(*i*) *Water Absorption.*—Methods of Test for Apparent Porosity, Water Absorption, Apparent Specific Gravity, and Bulk Density of Burned Refractory Products (A.S.T.M. Designation: C 20).[3]

(*j*) *Modulus of Rupture.*—Methods of Test for Cold Crushing Strength and Modulus of Rupture of Refractory Brick and Shapes (A.S.T.M. Designation: C 133).[3]

Standard Specifications for

REFRACTORIES FOR MODERATE DUTY STATIONARY BOILER SERVICE[1]

A.S.T.M. Designation: C 153 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 153; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) The purpose of these specifications is the selection of fireclay refractories for moderate duty boiler furnaces in which the temperature of the combustion chamber does not reach more than 2400 F. (1315 C.).

(*b*) These specifications are intended to cover only burned products made from fire clay by the usual processes of manufacture, and are not intended to include products other than those regularly sold as fireclay brick.

Zones of Highest Temperatures

2. The refractories to be used in the zones of highest temperatures, such as sidewalls, arches, doors, and jambs, shall be intermediate heat duty fireclay brick conforming to the requirements of type *H* (Section 5 (*a*)).

Zones of Lower Temperatures

3. The refractories to be used in the zones of lower temperatures, such as for backing up the brick in the zones of highest temperatures, and the walls beyond the first tube bank, shall be low heat duty fireclay brick conforming to the requirements of type *G* (Section 5 (*b*)).

REQUIREMENTS FOR THE TWO TYPES OF REFRACTORIES

Size and Warpage

4. The following permissible variations in size and warpage shall apply to each type of refractory listed in Section 5:

(*a*) *Size.*—When tested in accordance with the Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134) of the American Society for Testing Materials,[3] the standard 9-in. fireclay brick shall not show a size variation of

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these specifications were published as tentative from 1940 to 1941. These specifications comprise a revision of the requirements for moderate duty refractories formerly contained in the Standard Specifications for Fireclay Brick for Stationary Boiler Service (C 64 – 39). Editorially revised in 1942.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

more than plus or minus 2 per cent. Tile or shapes shall not show a size variation of more than plus or minus 2 per cent on dimensions of 4 in. or over, and plus or minus 3 per cent on dimensions smaller than 4 in.

(*b*) *Warpage.*—Ninety-five per cent of the shapes shall not show a warpage greater than 1 per cent of the diagonal used in making the measurement.

Test Requirements

5. (*a*) ***Type H.***—Type *H* shall be an intermediate heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 29, *or* not more than 3 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule D (2460 F., 1350 C.), of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

(*b*) ***Type G.***—Type *G* shall be a low heat duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 19.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 500 psi.

Retests

6. Because of variables resulting from sampling and the lack of perfect reproducibility in tests conducted by different laboratories, resampling and retesting may be carried out when requested by either the purchaser or the manufacturer. This may apply in instances where the first test result does not conform to the limits prescribed in these specifications. The final result to be used for each test shall be the average of the original and the retest figures.

NOTE.—A retest provision for variation in size is a part of that test method.

Methods of Testing

7. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Size.*—Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134).[3]

(*b*) *Warpage.*—Method of Test for Warpage of Refractory Brick and Tile (A.S.T.M. Designation: C 154).[3]

(*c*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*d*) *Load Test* (2460 F., 1350 C.).—Schedule No. 2 of the Method of Testing Fireclay Refractories Under Load at High Temperatures (A.S.T.M. Designation: C 16).[3]

(*e*) *Permanent Linear Shrinkage for Intermediate Heat Duty Brick* (2460 F., 1350 C.).—Schedule D of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*f*) *Modulus of Rupture.*—Methods of Test for Cold Crushing Strength and Modulus of Rupture of Refractory Brick and Shapes (A.S.T.M. Designation: C 133).[3]

[4] See the Classification of Fireclay Refractories (A.S.T.M. Designation C: 27), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

REFRACTORIES FOR INCINERATORS[1]

A.S.T.M. Designation: C 106 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 106; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) The purpose of these specifications is the selection of fireclay refractories for service in municipal and industrial incinerators under general conditions of operation and furnace design.

(*b*) These specifications are intended to cover only burned products made from fire clay by the usual processes of manufacture, and are not intended to include products other than those regularly sold as fireclay brick.

Zones of Highest Temperatures

2. The refractories to be used in the zones of highest temperatures, such as the main body of the furnace, crown, and target wall, shall be high heat duty fireclay brick conforming to the requirements of type *A* (Section 5 (*a*)).

Lining of Chimneys

3. Because of various conditions which may be encountered in different installations, there are provided in this section of the specifications three types of refractories for the lining of chimneys. In order to select the type best suited for a particular installation, careful consideration should be given to the conditions that will exist. Unless the high heat duty brick, type *A*, or the low heat duty brick, type *G* is definitely specified, there shall be supplied for this section of the specifications the intermediate heat duty brick, type *F*.

REQUIREMENTS FOR THE VARIOUS TYPES OF REFRACTORIES

Size and Warpage

4. The following permissible variations in size and warpage shall apply to each type of refractory listed in Section 5:

(*a*) *Size.*—When tested in accordance with the Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134) of the

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1934 to 1936, being revised in 1934. They were adopted in 1936, published as standard from 1936 to 1940, being revised in 1939, but withdrawn and republished as tentative from 1940 to 1941. Editorially revised in 1942.

American Society for Testing Materials,[3] the standard 9-in. fireclay brick shall not show a size variation of more than plus or minus 2 per cent. Tile or shapes shall not show a size variation of more than plus or minus 2 per cent on dimensions of 4 in. or over, and plus or minus 3 per cent on dimensions smaller than 4 in.

(*b*) *Warpage.*—Ninety-five per cent of the shapes shall not show a warpage greater than 1 per cent of the diagonal used in making the measurement.

Test Requirements

5. (*a*) ***Type A.***—Type *A* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31–32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

Spalling.—When subjected to the panel spalling test (preheated at 2910 F., 1600 C.), the brick shall not show a loss greater than 15 per cent.

(*b*) ***Type F.***—Type *F* shall be an intermediate heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 29, *or* not more than 3 per cent deformation in the 2460 F. (1350 C.) load test.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 500 psi.

(*c*) ***Type G.***—Type *G* shall be a low heat duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 19.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 500 psi.

Retests

6. Because of variables resulting from sampling and the lack of perfect reproducibility in tests conducted by different laboratories, resampling and retesting may be carried out when requested by either the purchaser or the manufacturer. This may apply in instances where the first test result does not conform to the limits prescribed in these specifications. The final result to be used for each test shall be the average of the original and the retest figures.

NOTE.—A retest provision for variation in size is a part of that test method.

Methods of Testing

7. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Size.*—Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134).[3]

(*b*) *Warpage.*—Method of Test for Warpage of Refractory Brick and Tile (A.S.T.M. Designation: C 154).[3]

(*c*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*d*) *Load Test* (2460 F., 1350 C.).—Schedule No. 2 of the Method of Testing Fireclay Refractories Under Load at High Temperatures (A.S.T.M. Designation: C 16).[3]

(*e*) *Permanent Linear Shrinkage for High Heat Duty Brick* (2550 F., 1400 C.).—Schedule B of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*f*) *Panel Spalling Test for High Heat Duty Brick* (2910 F., 1600 C.).—Method of Panel Test for Resistance to Thermal and Structural Spalling of High Heat Duty Fireclay Brick (A.S.T.M. Designation: C 107).[3]

(*g*) *Modulus of Rupture.*—Methods of Test for Cold Crushing Strength and Modulus of Rupture of Refractory Brick and Shapes (A.S.T.M. Designation: C 133).[3]

Standard Specifications for

REFRACTORIES FOR MALLEABLE IRON FURNACES WITH REMOVABLE BUNGS, AND FOR ANNEALING OVENS[1]

A.S.T.M. Designation: C 63 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 63; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) The purpose of these specifications is the selection of fireclay refractories for service in malleable furnaces and annealing ovens under general conditions of operation and furnace design.

(*b*) These specifications are intended to cover only burned products made from fire clay by the usual processes of manufacture, and are not intended to include products other than those regularly sold as fireclay brick.

Malleable Furnace Bungs

2. The refractories to be used in the bungs shall be a special type of fireclay brick conforming to the requirements of type *I* (Section 8 (*a*)).

Furnace Sidewalls and Bridgewalls

3. The refractories to be used in malleable furnace sidewalls and bridgewalls shall be high heat duty fireclay brick conforming to the requirements of type *J* (Section 8 (*b*)).

Lining of Fire boxes and Lower Portion of Stack

4. The refractories to be used in lining the fireboxes of malleable iron furnaces and of annealing ovens, and the lower portion of the stack, shall be high heat duty fireclay brick conforming to the requirements of type *K* (Section 8 (*c*)).

Upper Stack Lining

5. The refractories to be used in lining the upper portion of the stack shall be intermediate heat duty fireclay brick conforming to the requirements of type *H* (Section 8 (*d*)).

Annealing Oven Chamber

6. The refractories to be used in constructing the annealing oven chamber shall be low heat duty fireclay brick conforming to the requirements of type *L* (Section 8 (*e*)).

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1927 to 1928. They were adopted in 1928, published as standard from 1928 to 1934, but withdrawn and republished as tentative from 1934 to 1936. They were adopted in 1936, published as standard from 1936 to 1940, being revised in 1939, but withdrawn and republished as tentative from 1940 to 1941. Editorially revised in 1942.

REQUIREMENTS FOR THE VARIOUS TYPES OF REFRACTORIES

Size and Warpage

7. The following permissible variations in size and warpage shall apply to each type of refractory listed in Section 8:

(*a*) *Size.*—When tested in accordance with the Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134) of the American Society for Testing Materials,[3] the standard 9-in. fireclay brick shall not show a size variation of more than plus or minus 2 per cent. Tile or shapes shall not show a size variation of more than plus or minus 2 per cent on dimensions of 4 in. or over, and plus or minus 3 per cent on dimensions smaller than 4 in.

(*b*) *Warpage.*—Ninety-five per cent of the shapes shall not show a warpage greater than 1 per cent of the diagonal used in making the measurement.

Test Requirements

8. (*a*) ***Type I.***—Type *I* shall be a special type of fireclay refractory known as bung brick, conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 32.

Spalling.—When subjected to the panel spalling test (preheated at 2910 F., 1600 C.), the brick shall not show a loss greater than 7.5 per cent.

Modulus of Rupture.—The brick shall have a modulus of rupture of not less than 200 psi.

(*b*) ***Type J.***—Type *J* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 32.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

(*c*) ***Type K.***—Type *K* shall be a high heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31–32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule B (2550 F., 1400 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

(*d*) ***Type H.***—Type *H* shall be an intermediate heat duty[4] fireclay brick conforming to the following requirements:

Refractoriness.—The brick shall be required to meet only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 29, *or* not more than 3 per cent deformation in the 2460 F. (1350 C.) load test.

Permanent Linear Shrinkage.—When tested in accordance with schedule D (2460 F., 1350 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

(*e*) ***Type L.***—Type *L* shall be a low heat duty[4] fireclay brick conforming to the following requirements:

Pyrometric Cone Equivalent.—The brick shall have a P.C.E. not lower than cone No. 19.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] See the Classification of Fireclay Refractories (A.S.T.M. Designation: C 27), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Permanent Linear Shrinkage.—When tested in accordance with schedule A (2190 F., 1200 C.) of the permanent linear change test, the brick shall not show a contraction of more than 1.5 per cent.

Retests

9. Because of variables resulting from sampling and the lack of perfect reproducibility in tests conducted by different laboratories, resampling and retesting may be carried out when requested by either the purchaser or the manufacturer. This may apply in instances where the first test result does not conform to the limits prescribed in these specifications. The final result to be used for each test shall be the average of the original and the retest figures.

NOTE.—A retest provision for variation in size is a part of that test method.

Methods of Testing

10. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Size.*—Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134).[3]

(*b*) *Warpage.*—Method of Test for Warpage of Refractory Brick and Tile (A.S.T.M. Designation: C 154).[3]

(*c*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*d*) *Load Test* (2460 F., 1350 C.).—Schedule No. 2 of the Method of Testing Fireclay Refractories Under Load at High Temperatures (A.S.T.M. Designation: C 16).[3]

(*e*) *Permanent Linear Shrinkage for Low Heat Duty Brick* (2190 F., 1200 C.).—Schedule A of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*f*) *Permanent Linear Shrinkage for Intermediate Heat Duty Brick* (2460 F., 1350 C.).—Schedule D of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*g*) *Permanent Linear Shrinkage for High Heat Duty Brick* (2550 F., 1400 C.).—Schedule B of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*h*) *Panel Spalling Test for High Heat Duty Brick* (2910 F., 1600 C.).—Method of Panel Test for Resistance to Thermal and Structural Spalling of High Heat Duty Fireclay Brick (A.S.T.M. Designation: C 107).[3]

(*i*) *Modulus of Rupture.*—Methods of Test for Cold Crushing Strength and Modulus of Rupture of Refractory Brick and Shapes (A.S.T.M. Designation: C 133).[3]

Standard Specifications for

FIRECLAY PLASTIC REFRACTORIES FOR BOILER AND INCINERATOR SERVICES[1]

A.S.T.M. Designation: C 176 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 176; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover fireclay plastic refractories for use in boiler furnaces and municipal or industrial incinerators operated under general conditions of service.

(*b*) In addition to high heat duty plastic refractories for average service conditions, super duty plastic refractories are covered, because for some furnaces the design and operation may justify the use of the latter. The use of super duty plastic refractories may be desirable in the zone of highest temperature and when severe spalling or slagging is encountered, and especially when both slagging and spalling may occur to an unusual extent. Unless otherwise specified, high heat duty plastic refractories shall be supplied.

High Heat Duty Plastic Refractories Required for Average Service Conditions

2. (*a*) *Water Content.*—The plastic refractory as received shall contain not more than 15 per cent of water calculated on the basis of the wet weight.

(*b*) *Workability Index.* — The workability index of the plastic refractory as received shall be not less than 15 per cent nor more than 35 per cent deformation. The test specimen shall stand three tamps of the test weight without crumbling.

(*c*) *Pyrometric Cone Equivalent.*—The P.C.E. of the plastic refractory shall be not lower than cone No. 31.

(*d*) *Drying-and-Firing Shrinkage.*—The total drying-and-firing (2550 F., 1400 C.) linear shrinkage of the plastic refractory shall be not more than 4 per cent of the original length.

(*e*) *Panel Spalling Loss.*—The panel spalling (preheated at 2910 F., 1600 C.) loss of the plastic refractory shall be not more than 15 per cent.

Super Duty Plastic Refractories for Use in the Zone of Highest Temperature and Where Severe Spalling or Slagging Occurs

3. (*a*) *Water Content.*—The plastic refractory as received shall contain not

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these specifications were published as tentative from 1942 to 1944.

more than 15 per cent of water calculated on the basis of the wet weight.

(*b*) *Workability Index.* — The workability index of the plastic refractory as received shall be not less than 15 per cent nor more than 35 per cent deformation. The test specimen shall stand at least three tamps of the test weight without crumbling.

(*c*) *Pyrometric Cone Equivalent.*—The P.C.E. of the plastic refractory shall be not lower than cone No. 32½.

(*d*) *Drying-and-Firing Shrinkage.*—The total drying-and-firing (2910 F., 1600 C.) linear shrinkage of the plastic refractory shall be not more than 2.5 per cent of the original length.

(*e*) *Panel Spalling Loss.*—The panel spalling (preheated at 3000 F., 1650 C.) loss of the plastic refractory shall be not more than 5 per cent.

Retests

4. Because of the variables resulting from sampling and the lack of perfect reproducibility in tests conducted by different laboratories, the plastic refractory may be resampled and retested when requested by either the manufacturer or the purchaser. This may apply in instances where the first test result does not conform to the limits prescribed in these specifications. The final result to be used for each test shall be the average of the original and the retest values.

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Water Content.*—Methods of Test for Sieve Analysis and Water Content of Refractory Materials (A.S.T.M. Designation: C 92).[3]

(*b*) *Workability Index.*—Method of Test for Workability Index of Fireclay Plastic Refractories (A.S.T.M. Designation: C 181).[3]

(*c*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*d*) *Drying and Firing Shrinkage.*—Method of Test for Combined Drying and Firing Shrinkage of Fireclay Plastic Refractories (A.S.T.M. Designation: C 179).[3]

(*e*) *Panel Spalling Loss.*—Method of Panel Test for Resistance to Thermal and Structural Spalling of Fireclay Plastic Refractories (A.S.T.M. Designation: C 180).[3]

---

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

GROUND FIRE CLAY AS A MORTAR FOR LAYING-UP FIRECLAY BRICK[1]

A.S.T.M. Designation: C 105 - 41

ADOPTED, 1936; REVISED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 105; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover ground fire clays to be used in laying-up fireclay brick.

Quality

2. The material shall be sufficiently free from grit and of such quality and plasticity that it will spread satisfactorily with a trowel when tempered with adequate water.

Grades

3. There are two grades of ground fire clay, depending upon particle size, as follows:

	Designation
Commercial grade	C
Fine grade	F

Particle Size

4. (*a*) *Commercial Grade.*—Not more than 5 per cent shall be retained on a No. 20 A.S.T.M. sieve[3] (equivalent to mesh No. 20 of the Tyler standard series), and not more than 0.5 per cent shall be retained on a No. 16 A.S.T.M. sieve (equivalent to mesh No. 14 of the Tyler standard series).

(*b*) *Fine Grade.*—Not more than 5 per cent shall be retained on a No. 30 A.S.T.M. sieve[3] (equivalent to mesh No. 28 of the Tyler standard series), and not more than 0.5 per cent shall be retained on a No. 20 A.S.T.M. sieve (equivalent to mesh No. 20 of the Tyler standard series).

Classes

5. There shall be four classes of ground fire clay depending upon the grade of refractories with which they are to be used. These classes shall conform to the following requirements as to Pyrometric Cone Equivalent:

Class[4]	Pyrometric Cone Equivalent, Not Lower Than
Super duty	No. 31
High heat duty	No. 28
Intermediate heat duty	No. 26
Low heat duty	No. 16

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these specifications were published as tentative from 1934 to 1936. Editorially revised in 1943.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] Each class shall be suffixed by the designating letter C (commercial grade) or F (fine grade) depending upon the particle size required.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

Sampling

6. (*a*) *Containers.*—When ground fire clay is shipped in containers, a sample shall be taken as follows:

If the shipment consists of 100 containers or fraction thereof, the contents of one container, selected at random, shall be dumped and quartered to provide a 5-lb. sample for the laboratory. If the shipment consists of more than 100 containers, the number of containers to be sampled shall be as follows:

Number of Containers in Shipment	Number of Containers Selected for Sampling
Over 100 but less than 300	2
300 but less than 600	3
600 but less than 1000	4

In these cases, the several 5-lb. samples resulting from quartering shall be combined and either quartered or riffled to provide a 5-lb. sample for the laboratory.

(*b*) *Bulk.*—When ground fire clay is shipped in bulk, the sample shall be so taken that it will represent an average of all parts of the shipment from top to bottom and shall not contain a disproportionate share of the top and bottom layers. For a 30-ton unit, no less than 10 samples of approximately 25 lb. each shall be taken from different parts of the car or truck by digging holes spaced at equal intervals. If the shipment is more than 30 tons, a sample proportionately larger shall be taken. The combined samples shall be thoroughly mixed and quartered or riffled to provide a 5-lb. sample for the laboratory.

It shall be permissible to obtain the sample during unloading by taking a small scoopful of clay at regular intervals. One scoopful of clay, weighing approximately 1½ lb., shall be taken for each ton of material. In no case, however, shall the combined samples weigh less than 50 lb. The combined samples shall be thoroughly mixed and quartered or riffled to provide a 5-lb. sample for the laboratory.

Methods of Testing

7. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Particle Size.*—The procedure for wet sieve analysis as described in Section 5 of the Methods of Test for Sieve Analysis and Water Content of Refractory Materials (A.S.T.M. Designation: C 92).[4]

(*b*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[4]

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Classification of

FIRECLAY REFRACTORIES[1]

A.S.T.M. Designation: C 27 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 27; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This classification is intended principally to group fireclay brick according to their resistance to heat.

Super Duty Fireclay Brick

2. *Super Duty Fireclay Brick.*—A fireclay brick having a pyrometric cone equivalent not lower than cone No. 33 on the fired product, not more than 1 per cent linear shrinkage in the permanent linear change test, schedule C (2910 F., 1600 C.), and not more than 4 per cent loss in the panel spalling test (preheated at 3000 F., 1650 C.).

High Heat Duty Fireclay Brick

3. *High Heat Duty Fireclay Brick.*—A fireclay brick conforming to only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 31-32, *or* not more than 1.5 per cent deformation in the 2460 F. (1350 C.) load test.

Intermediate Heat Duty Fireclay Brick

4. *Intermediate Heat Duty Fireclay Brick.*—A fireclay brick conforming to only *one* of the following requirements: Pyrometric cone equivalent not lower than cone No. 29, *or* not more than 3 per cent deformation in the 2460 F. (1350 C.) load test.

Low Heat Duty Fireclay Brick

5. *Low Heat Duty Fireclay Brick.*—A fireclay brick having a pyrometric cone equivalent not lower than cone No. 19.

Alumina-Diaspore Fireclay Brick

6. (*a*) *50 per cent Alumina-Diaspore Fireclay Brick.*—Refractory brick having diaspore or nodular fire clay as an essential original ingredient, an alumina content of 50 ± 2.5 per cent, and a pyrometric cone equivalent not lower than cone No. 34.

(*b*) *60 per cent Alumina-Diaspore Fireclay Brick.*—Refractory brick having diaspore or nodular fire clay as an essential original ingredient, an alumina content of 60 ± 2.5 per cent, and a pyrometric cone equivalent not lower than cone No. 35.

[1] Under the standardization procedure of the Society, this classification is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to its present adoption as standard, this classification was published as tentative from 1919 to 1920. It was adopted in 1920, published as standard from 1920 to 1940, being revised in 1928, 1935, 1937, and 1939, but withdrawn and republished as tentative from 1940 to 1941. Editorially revised in 1942.

(*c*) *70 per cent Alumina-Diaspore Fireclay Brick.*—Refractory brick having diaspore as an essential original ingredient, an alumina content of 70 ± 2.5 per cent, and a pyrometric cone equivalent not lower than cone No. 36.

NOTE.—Definitions of diaspore clay and nodular fire clay appear in the Definitions of Terms Relating to Refractories (A.S.T.M. Designation: C 71) of the American Society for Testing Materials.[2]

Methods of Testing

7. The properties enumerated in this classification shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Pyrometric Cone Equivalent.*—Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24).[3]

(*b*) *Permanent Linear Shrinkage for Super Duty Brick* (2910 F., 1600 C.).—Schedule C of the Method of Test for Permanent Linear Change After Reheating of Refractory Brick (A.S.T.M. Designation: C 113).[3]

(*c*) *Panel Spalling Test for Super Duty Brick* (3000 F., 1650 C.).—Method of Panel Test for Resistance to Thermal and Structural Spalling of Super Duty Fireclay Brick (A.S.T.M. Designation: C 122).[3]

(*d*) *Load Test* (2460 F., 1350 C.).—Schedule No. 2 of the Method of Testing Fireclay Refractories Under Load at High Temperatures (A.S.T.M. Designation: C 16).[3]

(*e*) *Alumina Content.*—Methods of Chemical Analysis of Refractory Materials (A.S.T.M. Designation: C 18).[3]

---

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Methods of

CHEMICAL ANALYSIS OF REFRACTORY MATERIALS[1]

A.S.T.M. Designation: C 18 – 41

ADOPTED, 1939; REVISED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 18; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These methods cover procedures for the chemical analysis of fireclay, silica, high-alumina, and magnesite refractories, and of chrome ore and chrome refractories.

(*b*) The analytical procedures appear in the following order:

	Section
Fireclay Refractories:	
Moisture	7
Loss on Ignition	8
Silica	9
Iron, Aluminum, and Titanium Oxides	10
Iron Oxide	11
Titania	12
Alumina	13
Lime	14
Magnesia	15
Alkalies	16
Silica Refractories:	
Moisture	18
Loss on Ignition	19
Silica	20
Iron and Aluminum Oxides	21
Iron Oxide	22
Titania	23
Alumina	24
Lime	25
Magnesia	26
Alkalies	27
High-Alumina Refractories:	
Moisture	29
Loss on Ignition	30
Silica	31
Separation of Al_2O_3 and P_2O_5 from Fe_2O_3, TiO_2, CaO, and MgO	32
Iron Oxide	33
Titania	34
Phosphorus Oxide	35
Alumina	36
Lime	37
Magnesia	38
Alkalies	39
Magnesite Refractories:	
Moisture	42
Loss on Ignition	43
Silica	44
Iron and Aluminum Oxides	45
Iron Oxides	46
Alumina	47
Lime	48
Magnesia	49
Manganese as MnO	50
Chrome Ore and Chrome Refractories:	
Moisture	53
Loss on Ignition	54
Chromium Oxide	55
Titania and Ferrous Oxide	56
Titania	57
Ferrous Oxide	58
Silica	59
Alumina	60
Lime	61
Manganese as MnO	62
Magnesia	63

NOTE.—These methods have been compiled as standard procedures for use in referee analyses. These methods, however, when the determination of iron oxide as Fe_2O_3 is involved, are not intended to preclude the use of other procedures that give results within the permissible varia-

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to their present adoption as standard, these methods were published as tentative from 1917 to 1920, being revised in 1918. They were adopted in 1920, published as standard from 1920 to 1937, being revised in 1935, but were withdrawn and published as tentative from 1937 to 1939.

tions. For the sake of uniformity the classical Zimmerman-Reinhardt procedure is specified for the determination of iron oxide. It is recognized that numerous other procedures are equally accurate and often more convenient. The other procedures commonly in use include reduction of an oxidized solution with zinc or other metal, and titration with standard $KMnO_4$ or $K_2Cr_2O_7$, as well as titration with a standard solution of titanous chloride in an oxidized solution. These procedures shall be considered acceptable provided the analyst has obtained results by his special procedure which check with the Zimmerman-Reinhardt procedure within the limits specified in Section 6. It is suggested that the National Bureau of Standards' standard samples be used for checking the accuracy of procedures.

It will be understood that the making of a complete analysis of a refractory material is a difficult procedure requiring a wide knowledge of the chemistry involved in the operations and a thorough training in carrying out the work. A skilled analyst of good training is therefore required to do the work. The descriptions here given cover the vital points of procedure, but frequent reference in regard to the details of the various manipulations should be made to "Applied Inorganic Analysis" by Hillebrand and Lundell[3] and to similar publications. Particularly in the determination of alumina, reference should be made to *Scientific Paper No. 286* of the National Bureau of Standards.[4]

Reagents and Special Solutions Required

2. The lists in Paragraphs (*a*) to (*n*) include those reagents and special solutions common to two or more of the analytical procedures. Other special reagents and solutions required will be found listed with the particular method in which they are prescribed.

(*a*) *Concentrated Acids and Ammonium Hydroxide.*—Concentrated c.p. acids and ammonium hydroxide of approximately the following specific gravities or concentrations will be required:

Hydrochloric acid, HCl	1.19 sp. gr.
Nitric acid, HNO_3	1.42 sp. gr.
Sulfuric acid, H_2SO_4	1.84 sp. gr.
Hydrofluoric acid, HF	40 per cent
Perchloric acid, $HClO_4$	60 to 70 per cent, c. p.[a]
Sulfurous acid	6 per cent solution[b]
Ammonium hydroxide, NH_4OH	0.90 sp. gr.

[a] Lower purity varieties may contain aluminum oxide, Al_2O_3, as an impurity.
[b] As supplied by reagent manufacturers.

(*b*) *Diluted Acids and Ammonium Hydroxide.*—The diluted acids and ammonium hydroxide referred to are of varying percentages by volume. They shall be made up by mixing proportional volumes of the concentrated reagent and water. The diluted sulfuric acid mixtures shall be made up by slowly stirring the acid into the water. These diluted acids and ammonium hydroxide are designated in the methods as (1:4), (1:9), etc., except very diluted solutions which are referred to by the percentage of reagent added. The designation in parentheses indicates the ratio of the volume of the concentrated reagent to the volume of water; for example, H_2SO_4 (1:9) contains 10 per cent by volume of H_2SO_4 (sp. gr. 1.84). The following will be required:

	Percentage by Volume
Hydrochloric acid	50 20
Sulfuric acid	50 10 5
Nitric acid	30 3
Ammonium hydroxide	50 5

(*c*) *Ammonium Chloride (2 per cent).*—Dissolve 2 g. of NH_4Cl in 100 ml. of water.

(*d*) *Ammonium Oxalate (Saturated Solution).*—Dissolve 4 g. of $(NH_4)_2C_2O_4$ in 100 ml. of water.

(*e*) *Standard Potassium Permanganate (0.1 N).*—Dissolve 3.25 g. of $KMnO_4$ in 1000 ml. of water. Standardize against the National Bureau of Standards' standard sample 40*c* of sodium oxalate.

[3] W. F. Hillebrand and G. E. F. Lundell, "Applied Inorganic Analysis," Wiley and Son, New York City (1929).
[4] W. Blum, "Determination of Alumina as Oxide," National Bureau of Standards *Scientific Paper No. 286.*

(*f*) *Standard Potassium Permanganate* (*0.04 N*).—Dissolve 2.5 g. of $KMnO_4$ in water and make up to 2 liters. Allow to stand for a week, filter through an asbestos mat, and keep in a dark place. Standardize against the National Bureau of Standards' standard sample 40*c* of sodium oxalate.

(*g*) *Standard Titania Solution.*—Weigh out 0.05 g. of pure calcined TiO_2. Fuse with 10 g. of $K_2S_2O_7$ in a clean platinum crucible, keeping the temperature as low as possible to maintain fluidity. Cool, and dissolve in about 300 ml. of diluted H_2SO_4 (1:5). Cool, transfer to a 500-ml. volumetric flask, dilute to the mark with water, and mix thoroughly. To standardize the solution, take two 50-ml. portions in 400-ml. beakers, dilute, boil, and precipitate with NH_4OH. Filter, and wash with hot water. Place the papers in the original beakers, add 15 ml. of HCl, stir to macerate the paper, dilute, and precipitate again with NH_4OH. Filter, and wash with hot water until free of alkali salts. Ignite carefully, blast, and weigh. From the weight determined, calculate the strength of the solution.

(*h*) *Standard Sodium Arsenite Solution.*—Dissolve 0.908 g. of pure arsenious oxide, As_2O_3, in a small amount of hot Na_2CO_3 solution, cool, filter, and dilute to 1 liter. Standardize against a steel of known manganese content.

(*i*) *Stannous Chloride Solution.*—Dissolve 50 g. of $SnCl_2$ in 100 ml. of HCl and dilute to 1000 ml. Keep a few pieces of metallic tin in the bottle.

(*j*) *Mercuric Chloride Solution.*—Prepare a saturated solution of $HgCl_2$.

(*k*) *Manganese Sulfate Solution.*[4a]—Dissolve 70 g. of crystalline $MnSO_4$ in 500 ml. of water. Add 140 ml. of phosphoric acid, H_3PO_4, (sp. gr. 1.7) and 130 ml. of H_2SO_4 (sp. gr. 1.84). Dilute to 1 liter.

(*l*) *Hydrogen Peroxide* (*30 per cent*).

(*m*) *Diammonium Phosphate Solution.*—Dissolve 10 g. of $(NH_4)_2HPO_4$ in 100 ml. of water.

(*n*) *Chloroplatinic Acid Solution* (*10 per cent*).

(*o*) *Ethyl Alcohol* (80 *per cent*).—Prepare a solution containing 80 per cent by volume of ethyl alcohol in water.

(*p*) *Ethyl Alcohol* (*Absolute*).—Certain commercial brands of denatured absolute alcohol are satisfactory as well as being considerably less expensive than the c.p. absolute alcohol.

Preparation of Samples for Analysis

3. The sample, carefully obtained by one of the approved methods of sampling, shall be crushed in a small jaw or roll-type crusher with hardened tool-steel faces to pass a No. 8 (2380-micron) sieve.[5] The sample shall then be crushed to pass a No. 20 (840-micron) sieve,[5] mixed, and quartered to about 50 g. This 50-g. sample shall then be ground so that it will all pass a No. 100 (149-micron) sieve,[5] unless otherwise specified, mixed thoroughly, and placed in a container which will insure freedom from contamination. Fine grinding shall be done in an agate mortar, either by hand or by a mechanical sample grinder of the McKenna, Carling, Fisher, or similar type so constructed as to prevent the introduction of impurity.

Statement of Analysis[5a]

4. Moisture shall be determined on the sample in its ordinary air-dried condition. All other percentage compositions shall be determined on moisture-free samples and reported, accordingly, on a moisture-free basis. The drying temperature recommended for all mois-

[4a] This paragraph was editorially revised in 1943.

[5] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[5a] This section was editorially revised in 1942.

ture determinations is 105 to 110 C., although it is recognized that in the case of certain raw fire clays a temperature as high as 140 C. may be required for complete removal of all hygroscopic moisture.[6] Whenever a sample is weighed out for any determination other than moisture, it shall be moisture-free. If preferred, the sample may be dried in a weighing bottle from which the required samples shall be weighed out.

Blank Determinations

5. Blank determinations on the reagents shall be made for each constituent in the refractory and this blank deducted in each case. For the determination of the silica blank, approximately 0.25 g. of Al_2O_3 should be added as pure aluminum chloride.

Reproducibility of Results

6. In all cases, check determinations shall be made, and the results shall be redetermined if satisfactory checks are not obtained. Results shall be considered satisfactory if the differences between check determinations do not exceed the following limits:

	Permissible Variations Between Check Determinations, max., per cent
For silica or other constituent amounting to 30 per cent[a] or over	0.3
For alumina or other constituent amounting to 10 to 30 per cent[a]	0.2
For any other constituent amounting to under 10 per cent[a]	0.1

[a] These figures are stated in terms of the whole sample as 100 per cent.

FIRECLAY REFRACTORIES

Moisture

7. Weigh 1.00 g. of the sample and heat to constant weight at a temperature not under 105 nor over 110 C. Record the loss in weight as moisture.

Loss on Ignition

8. Weigh 1.000 g. of the moisture-free (105 to 110 C.) sample and heat to constant weight over a blast lamp, or in an electric muffle furnace, at 900 to 1000 C. Record the loss in weight as the ignition loss.

Silica

9. Weigh 0.5000 g. of the moisture-free (105 to 110 C.) sample into a platinum crucible containing about 5 g. of powdered anhydrous Na_2CO_3 and mix well with a platinum wire. Cover the mixture with a little more Na_2CO_3. Heat gradually to the full heat of a good burner (1000 to 1100 C.) maintained for about 1 hr. until complete solution is obtained. Place the crucible cover on a triangle, and when the melt has partially cooled pour it on the lid (Note). When cool, place the crucible and lid in a 150-ml. beaker, placing the button on a watch glass above the beaker. Add 30 ml. of HCl (1:1). When solution is complete wash off the crucible and lid with HCl (1:4), taking care to remove all SiO_2. Place the button in the solution. Transfer the contents of the beaker to an evaporating dish and evaporate to dryness on a steam bath. Bake for 1 hr. at 110 C. Add 20 to 30 ml. of HCl (1:1) and 50 ml. of hot water. When all salts have been dissolved, allow to settle for several minutes and then filter through a No. 40 Whatman paper or equivalent. Wash the SiO_2 three times by decantation using 20 to 30-ml. portions of first hot water, then HCl (1:1), then hot water again. Transfer the precipitate to the filter paper, removing all SiO_2 from the dish with a policeman. Wash the paper and precipitate with hot water until free from salt. To recover the small amount of

[6] See National Bureau of Standards' Certificates of Analysis of Standard Samples of Fire Clays, Nos. 97 and 98, August 31, 1931.

SiO_2 remaining in the filtrate, evaporate to dryness, using the same procedure for baking and filtering as before. Combine the two precipitates, place in a platinum crucible, and burn off the paper carefully to prevent any loss of SiO_2. Ignite the sample to constant weight at 1100 to 1200 C. (15 to 20 min. is usually sufficient), cool in a desiccator, and weigh. Moisten the residue with several milliliters of water, add 10 ml. of HF and 3 or 4 drops of H_2SO_4. Evaporate the solution to dryness, ignite carefully to prevent decrepitation, and blast for several minutes at 1100 C. Cool the crucible in a desiccator, weigh, and repeat blasting to constant weight. The loss in weight from the original silica residue represents the SiO_2 content, except for that part of the SiO_2 which is later recovered from alumina, etc.

NOTE.—Another scheme to aid in subsequent solution of the fused melt is to rotate the crucible as it cools, spreading the mass up the side walls.

Iron, Aluminum, and Titanium Oxides

10. Fuse the residue with 1 g. of fused $K_2S_2O_7$ or $Na_2S_2O_7$, dissolve in a small amount of water, and add to the filtrate from the silica determination (Section 9). Add 5 g. of NH_4Cl and 3 drops of methyl red solution (0.1 per cent). Heat the solution almost to boiling, and add slowly NH_4OH (1:1) until the indicator has changed to a yellow color. Boil for several minutes to remove the excess ammonia. Allow to settle for 30 min. and decant through a No. 41 Whatman filter paper or equivalent, transferring the precipitate to the paper and washing the beaker and paper several times with a warm NH_4Cl solution (2 per cent). Reserve the filtrate, *A*, for the determination of CaO and MgO (Section 14). Return the precipitate to the original beaker, add 50 ml. of hot water and 10 ml. of HCl (sp. gr. 1.19). Stir until the precipitate is dissolved and the paper is well macerated. Dilute to about 200 ml. with hot water, precipitate and filter as before. Combine this filtrate *B* with filtrate *A*. Wash the paper and precipitate with a warm NH_4Cl solution (2 per cent). Place the precipitate in a weighed platinum crucible and ignite. Continue the ignition at 1200 C. to constant weight (15 to 20 min. is usually sufficient). Cool in a desiccator, and weigh with the crucible covered with the lid. The R_2O_3 consists of the Al_2O_3, TiO_2, and Fe_2O_3 present in the sample. In addition there may be small amounts of P_2O_5, ZrO_2, V_2O_5 and Cr_2O_3.

Iron Oxide

11. (*a*) *Method A: Fe_2O_3 Determined on R_2O_3 Sample.*—Heat the R_2O_3 precipitate (Note) obtained in the determination of iron, aluminum, and titanium oxides (Section 10) with fused $K_2S_2O_7$ or $Na_2S_2O_7$ until solution is complete. Dissolve the fusion in 50 ml. of H_2SO_4 (1:9) and evaporate to fumes. Cool, dilute with water, and filter off the SiO_2, washing with hot water. Reserve the filtrate for the determination of Fe_2O_3 and TiO_2. Ignite the SiO_2 in a platinum crucible and weigh. Treat the precipitate with 5 ml. of HF and 2 or 3 drops of H_2SO_4. Evaporate to dryness, ignite, and weigh. The loss in weight represents extra SiO_2 which should be added to that determined previously and also deducted from the weight of the R_2O_3 precipitate. Evaporate the filtrate obtained in correcting the R_2O_3 precipitate for SiO_2 to about 75 ml. Cool, and dilute to 100 ml. in a volumetric flask. Reserve 25 ml. for the determination of TiO_2 (Section 12). To the remainder, add 25 ml. of HCl (1:1) and heat to boiling. Reduce the iron by adding $SnCl_2$ solution drop by drop from a pipette with constant swirling of the beaker until the solution is

colorless. Then add one drop in excess. Cool quickly in running water, then add at one stroke 15 ml. of saturated $HgCl_2$ solution. Allow to stand for 3 min., then transfer with washing to a 1000-ml. beaker containing 300 ml. of cold distilled water and 25 ml. of $MnSO_4$ solution. Titrate with standard 0.04 *N* $KMnO_4$, added very slowly while stirring constantly, until a permanent pink end point is obtained.

NOTE.—Instead of fusing directly in the platinum crucible in which the R_2O_3 was ignited, the precipitate may be brushed into a porcelain crucible and then fused with $K_2S_2O_7$ or $Na_2S_2O_7$. This avoids loss of platinum by the action of the pyrosulfate, and no platinum is present in the filtrate to interfere with the iron determination.

(*b*) *Method B: Fe_2O_3 Determined on a Separate Sample.*—Weigh 1.00 g. of the finely ground, moisture-free (105 to 110 C.) sample into a platinum crucible, add 10 drops perchloric acid ($HClO_4$) and 20 ml. of HF, and heat almost to dryness on a hot plate. Add 5 to 10 ml. of $HClO_4$ and heat until residue has dissolved (Note). Cool, place crucible in a 400-ml. beaker, add 100 ml. of water, and heat to boiling. Any residue present, other than SiO_2, should be filtered off and fused with $K_2S_2O_7$ or $Na_2S_2O_7$ in a porcelain crucible and added to the main solution.

NOTE.—Decomposition of raw fire clays and some fired refractories can be effected equally as well by substituting an equal volume of H_2SO_4 (1:1) for the $HClO_4$. In this case, heat to fumes once, cool, dilute, filter, and fuse any residue remaining undissolved.

(*c*) Determine iron, using one of the approved methods referred to in the note under Section 1.

Titania

12. Determine TiO_2 colorimetrically in the 25-ml. portion reserved for this purpose (Section 11) by oxidizing both the sample and the standard TiO_2 solution with several drops of a H_2O_2 solution (30 per cent). Compare the colors either in Nessler tubes or in a suitable colorimeter. Use a H_2SO_4 solution (5 per cent) for diluting purposes in matching the colors.

Alumina

13. Subtract the calculated weight of Fe_2O_3 (Section 11 (*a*) or (*b*)), TiO_2 (Section 12), and SiO_2 (Section 9) from the weight of R_2O_3 (Section 10). The remainder is the weight of Al_2O_3 plus small amounts of the oxides which may include those previously mentioned in Section 10. These are generally considered as Al_2O_3 in reporting the analysis of fireclay refractories.

Lime

14. Evaporate the combined filtrates reserved (Section 10) for the determination of CaO and MgO to about 200 ml., add 10 to 15 ml. of the saturated ammonium oxalate solution and 2 to 3 ml. of NH_4OH. Heat for 1 to 2 hr., by which time the volume should be about 75 to 100 ml. Allow the precipitated calcium oxalate to settle. Decant through a dense filter paper (Whatman No. 40 or equivalent), taking care to retain the precipitate in the beaker, wash several times with warm water by decantation, and then wash the paper until free from soluble salts. Reserve the filtrate for the MgO determination (Section 15). Return the paper to the beaker containing the precipitate, add 100 ml. of a H_2SO_4 solution (5 per cent), warm, and titrate to a faint pink end point with standard 0.04 *N* $KMnO_4$ solution. A blank should be previously determined for the effect of the paper.

NOTE.—For greater accuracy a double precipitation should be made, in which case, after precipitating the calcium oxalate as described above, decant the liquid and wash the beaker and paper several times with warm water. Dissolve the precipitate on the paper with warm

HCl (1:4), allowing it to run into the beaker containing the major portion of the calcium oxalate. Wash the paper with hot water. To the solution (about 75 to 100 ml. in volume) add several milliliters of saturated $(NH_4)_2C_2O_4$ solution and NH_4OH in slight excess. Heat for 2 hr., filter, wash, and titrate as described above.

Magnesia

15. Evaporate the filtrate from the CaO determination (Section 14) to about 150 to 200 ml. and add 2 to 3 g. of diammonium phosphate ($(NH_4)_2HPO_4$), stir until dissolved, and then add NH_4OH until alkaline and then 20 ml. in excess. Allow the solution to stand overnight. Filter and wash with NH_4OH (5 per cent). Dissolve the precipitate on the paper with hot HCl (1:4), allowing it to run into the beaker containing the precipitate. Wash the paper with hot water. To the solution, which should be not more than 100 ml. in volume, add 0.1 to 0.2 g. of $(NH_4)_2HPO_4$. Make ammoniacal, and then add a slight excess while stirring constantly until the precipitate is well formed. Then add 10 ml. more of NH_4OH and allow to stand overnight or at least for 4 hr. Filter through a No. 40 Whatman paper or equivalent. Transfer the precipitate to the paper and wash well with NH_4OH (5 per cent). Place the paper in a weighed platinum crucible, burn off the paper at a low temperature (below 900 C.), and ignite to constant weight at 1050 to 1100 C. (15 to 30 min. is sufficient).

Alkalies[7]

16. (*a*) Weigh 1.00 g. of the moisture-free (105 to 110 C.) sample (ground to an impalpable powder) and 3.0 g. of NH_4Cl into an agate mortar and mix well. Add 7 to 8 g. of $CaCO_3$ and again mix intimately. Place a $\frac{1}{8}$-in. layer of $CaCO_3$ in the bottom of a platinum crucible, and then add the above mixture, tapping the crucible occasionally to obtain a dense mass. Place a $\frac{1}{8}$-in. layer of $CaCO_3$ on the top. Heat the crucible over a low flame until ammonia fumes are no longer given off, then increase the heat so that the bottom half of the crucible is a dull red and maintain this temperature for about 1 hr. Cool, fill the crucible three-fourths full of water, and heat until the contents can be taken out and crushed in an agate mortar. Transfer to a platinum or porcelain dish by means of a jet of water. Evaporate to a low volume, decant through a No. 40 Whatman filter paper, or equivalent, and wash the material in the dish several times by decantation with warm water. Transfer to the paper and wash several times with hot water. Acidify with several milliliters of HCl and evaporate to a volume of 150 to 200 ml. Add several milliliters of NH_4OH and sufficient $(NH_4)_2CO_3$ to precipitate the lime, keeping the dish covered with a watch glass. Warm until the precipitate settles out. Filter and wash with warm water. Evaporate the solution to a low volume, then add a small lump of $(NH_4)_2CO_3$ to determine whether practically all calcium has been precipitated. If no precipitate forms, evaporate to dryness, otherwise precipitate and filter as before. Drive off the ammonium salts by heating just short of a dull red. Dissolve the residue in water and add a few milliliters of a saturated solution of $(NH_4)_2C_2O_4$ and 1 to 2 ml. of NH_4OH to precipitate the last trace of calcium. Heat for 30 to 45 min., filter, and wash with water containing $(NH_4)_2C_2O_4$ (0.1 per cent). Catch the filtrate in a weighed platinum dish. Add several drops of HCl and evaporate to dryness. Ignite gently as before and weigh as NaCl and KCl.

(*b*) The separation of the potassium and sodium must be carried out in an atmosphere free from ammonia fumes. Add to the solution of the combined chlorides in a small porcelain dish, sufficient chloroplatinic acid solution to re-

[7] This procedure for the determination of alkali is the J. Lawrence Smith method.

act with all of the sodium and potassium. The necessary amount to use is readily calculated from the known strength of the platinum solution and the weight of mixed chlorides counted as NaCl. The dilution of the resulting solution should be such that when heated on the steam bath any precipitate that may have formed entirely dissolves. This is to prevent inclusion of mother liquor in a mass of crystals suddenly formed. Evaporate until the solution is just syrupy enough to solidify on cooling. Do not evaporate to dryness, as this will dehydrate the sodium salt and render it less soluble in alcohol. Drench the residue with alcohol (80 per cent), filter by decantation through a small paper, wash by decantation with more of the alcohol, crushing the crystals with a small pestle or a widened and rounded end of a short glass rod. Reserve the filtrate and washings if sodium is to be determined directly. The residue should be golden yellow. An orange-red color indicates incomplete removal of the sodium salt. It is unnecessary to bring the mass of the precipitate upon the filter. Dry the dish and paper for a few moments to remove adhering alcohol. Dissolve the precipitate on the filter with hot water, catching the solution in a weighed crucible or small dish of platinum. Evaporate to dryness and add the salt that is still in the porcelain dish. If the salt is at all lumpy, redissolve it in water and again evaporate to dryness. Heat for 1 hr. at 130 C. in an air oven (100 C. suffices for very small amounts of fine-grained precipitate). It is necessary to cover the receptacle at first because the precipitate is prone to decrepitate. When dry, cool and weigh as K_2PtCl_6. Calculate the oxides, as follows:

$$KCl = \text{wt. of } K_2PtCl_6 \times 0.3068$$
$$K_2O = \text{wt. of } K_2PtCl_6 \times 0.1941$$
$$NaCl = \text{total chlorides} - KCl$$
$$Na_2O = NaCl \times 0.5303$$

SILICA REFRACTORIES

Special Solutions and Reagents Required

17. (*a*) *Sulfuric Acid* (*25 per cent by volume*).

(*b*) *Nitric Acid* (*50 per cent by volume*).

(*c*) *Standard Potassium Permanganate* (*0.01 N*).—Dissolve 0.325 g. in 1000 ml. of water. Standardize against the National Bureau of Standards' standard sample 40*c* of sodium oxalate.

Moisture

18. Weigh 1.00 g. of the sample and heat to constant weight at a temperature not under 105 nor over 110 C. Record the loss in weight as moisture.

Loss on Ignition

19. Weigh 1.000 g. of the moisture-free (105 to 110 C.) sample and heat to constant weight over a blast lamp, or in an electric muffle furnace, at 900 to 1000 C. Record the loss in weight as the ignition loss.

Silica

20. Transfer 1.0000 g. of the moisture-free (105 to 110 C.) sample to a 30-ml. platinum crucible. Add 10 ml. of HNO_3 (1:1) and 5 ml. of HF. Cover the crucible, place on a hot plate on an asbestos pad, and heat. Heat gently at first, gradually increasing the temperature. The final temperature should be regulated to prevent boiling or spattering. Heating in this manner for 1 hr. is sufficient to decompose the sample. Rinse the underside of the crucible lid with a few drops of water, allowing it to run into the crucible. Evaporate the crucible contents to dryness. Cool, add 10 ml. of HNO_3 (1:1), and again evaporate to dryness. Introduce the acid slowly by pouring it down the sides of

the crucible. Evaporate three times with the HNO_3 to insure complete volatilization of the fluorides. Ignite gently at first and then finally to constant weight at about 1200 C. Cool in a desiccator, and weigh. The loss in weight minus the loss on ignition (Section 19) represents all but a possible trace of the SiO_2 in the sample.

Iron and Aluminum Oxides

21. Fuse the residue in the crucible from the silica determination (Section 20) by heating gently with about 2 g. of potassium pyrosulfate, $K_2S_2O_7$, or sodium pyrosulfate, $Na_2S_2O_7$; cool, dissolve in water, and acidify with 3 to 4 ml. of HCl. Dilute to 150 to 200 ml., add 5 g. of NH_4Cl and 3 drops of methyl red (0.1 per cent). Heat to boiling, add NH_4OH (1:1) slowly, finally drop by drop until the solution is just alkaline to the indicator. Boil for 1 to 2 min. and filter through a 9-cm. rapid filter paper. Do not wash. Reserve the filtrate. Transfer the paper and precipitate to the beaker in which the precipitation was made, add 50 ml. of HCl (1:4), and digest covered on the hot plate, shaking frequently until the precipitate is dissolved and the paper well macerated. Dilute, add methyl red, reprecipitate with NH_4OH (1:1), boil, and filter, exactly as before. Add this second filtrate to the first filtrate for the subsequent determination of lime (Section 25). Swab the beaker and rod, and wash the paper and precipitate with NH_4Cl (2 per cent). Dry, then ignite the paper and precipitate to constant weight in a tared platinum crucible of 30-ml. capacity at 1000 to 1100 C. with access to air. Cool in a desiccator, and weigh as R_2O_3 which is mainly the iron and aluminum oxides. To recover the trace of SiO_2 which may have remained with the R_2O_3 group, add 2 drops of H_2SO_4 (1:4) and 1 ml. of HF to the crucible and evaporate to dryness. Cover the crucible and ignite to constant weight at about 1100 C. Cool and weigh. The loss in weight represents additional SiO_2 which should be added to that determined in Section 20.

Iron Oxide

22. Transfer 1.00 g. of the moisture-free (105 to 110 C.) sample to a 30-ml. platinum crucible and moisten with a few drops of water. Add 3 ml. of HNO_3, and about 15 ml. of HF. Evaporate at a moderate heat to dryness, taking care not to allow any loss by spattering. Decompose the nitrates and fluorides by ignition at about 1000 C. for 15 min. Now add to the residue in the crucible a small piece of $K_2S_2O_7$ or $Na_2S_2O_7$, and fuse. Dissolve the fusion in 25 ml. of HCl (1:1) and heat to boiling. Reduce the iron by adding $SnCl_2$ solution drop by drop from a pipette with constant swirling of the beaker until the solution is colorless, then add 1 drop in excess. Cool quickly in running water, then add at one stroke 15 ml. of saturated $HgCl_2$ solution. Allow to stand for 3 min., transfer with washing to a 1000-ml. beaker containing 300 ml. of cold distilled water and 25 ml. of $MnSO_4$ solution. Titrate with standard 0.01 *N* $KMnO_4$, added very slowly while stirring constantly, until a permanent pink end point is obtained.

Titania

23. Fuse the ignited R_2O_3 residue after recovery of SiO_2 (Section 21) with a very small piece of $K_2S_2O_7$ or $Na_2S_2O_7$. Cool, and dissolve the fusion by the addition of about 25 ml. of warm water and 1 to 2 ml. of H_2SO_4 to the crucible. It is important at this point to keep the solution to a small volume. Transfer to a 50-ml. volumetric flask, add a few drops of H_2O_2, and dilute to the mark. Place the 50 ml. of solution in a small

Nessler tube. Compare the color of this solution with the color of a known standard solution. A satisfactory solution is one of such strength that 1 ml. equals 0.0001 g. of TiO_2. To make the comparison use any standard colorimeter, or place an appropriate amount of standard solution in a second Nessler tube and dilute with water from a burette until the color is matched. From the amount of water added, calculate the percentage of TiO_2 in the sample.

Alumina

24. Subtract the calculated weight of Fe_2O_3 (Section 22), the weight of SiO_2 recovered (Section 21), and the calculated weight of TiO_2 (Section 23) from the weight of R_2O_3 (Section 21). The remainder is the weight of the Al_2O_3, plus small amounts of oxides of any other elements that were precipitated.

NOTE.—These may include P_2O_5 and ZrO_2, but they are present in such small amounts as to be disregarded in the complete analysis of silica refractories.

Lime

25. Acidify the combined filtrate from the R_2O_3 precipitation with several milliliters of HCl (1:1) (Section 21) and evaporate to a volume of about 250 ml. Heat to incipient boiling, add 25 ml. of a saturated $(NH_4)_2C_2O_4$ solution and NH_4OH until slightly alkaline. Stir thoroughly and allow the precipitate to settle out, keeping the solution warm for 3 to 4 hr. but not boiling. Filter and wash five times with cold water. Save the filtrate. Dissolved the washed oxalate precipitate with 50 ml. of diluted HCl (1:1), dilute to about 150 ml., and precipitate as before. Wash the beaker, precipitate, and paper with cold water until $(NH_4)_2C_2O_4$ is removed. Avoid excessive washing. Combine the filtrates for the magnesia determination (Section 26). To the beaker used for the precipitation, add 150 ml. of a H_2SO_4 solution (5 per cent), then introduce the paper containing the precipitate. Heat to almost boiling and titrate with 0.1 *N* $KMnO_4$. A blank should be previously determined for the effect of the paper.

Magnesia

26. To the combined filtrates from the lime determination (Section 25), which have been reduced by evaporation to about 300 ml., add 2 to 3 g. of $(NH_4)_2HPO_4$. Stir until dissolved and then add NH_4OH slowly until alkaline, and then 30 ml. of NH_4OH in excess. Allow the solution to stand for at least 4 hr., and preferably overnight if the total amount of solution exceeds 400 ml. in volume. Filter, wash with diluted NH_4OH (5 per cent). Dissolve from the paper with hot HCl (1:1) and reprecipitate by adding 0.1 g. of $(NH_4)_2HPO_4$, diluting, rendering ammoniacal, and letting stand as before. After filtering and washing as before, char the paper and burn off the carbon below 900 C., and then ignite in an electric muffle furnace at about 1100 C. to constant weight. The ignited material consists of magnesium pyrophosphate, $Mg_2P_2O_7$. Calculate the weight of MgO by multiplying the $Mg_2P_2O_7$ by 0.3621.

Alkalies

27. Determine the alkalies by the procedure described in Section 16 (*a*) and (*b*) for the analysis of fireclay refractories.

HIGH-ALUMINA REFRACTORIES

(Includes Bonded Refractories made from Diaspore, Fused Alumina, and the Sillimanite Minerals, as well as Electrocast.)

Special Solutions Required

28. (*a*) *Potassium Nitrate (1 per cent).*—Dissolve 1 g. in 100 ml. of water.

(*b*) *Molybdate Reagent.*—Mix 100 g. of pure molybdic anhydride or 118 g. of molybdic acid (85 per cent) with 400 ml. of water, add 80 ml. of NH_4OH, and filter when solution is complete. Prepare a second solution containing 400 ml. of HNO_3 and 600 ml. of water. Agitate the HNO_3 solution by means of a current of air and add the molybdate solution very slowly. Continue agitation for 1 hr. Add a small crystal of $(NH_4)_2HPO_4$, let stand over night, filter, and keep in a glass-stoppered bottle.

(*c*) *Standard Sodium Hydroxide Solution.*[4a]—Dissolve 60 g. of NaOH in 100 ml. of distilled water in a 150-ml. test tube of resistant glass. Stopper tightly with a cork covered with tin foil and let stand until the supernatant liquid is clear. By means of a pipette take out 5.0 ml. of the clear solution and dilute to 1 liter with freshly boiled water (Note).

(*d*) *Standard Nitric Acid Solution.*[4a]—Dilute 5.0 ml. of HNO_3 (sp. gr. 1.42) to 1 liter with freshly boiled water (Note).

NOTE.—Adjust the NaOH and HNO_3 solutions until they exactly agree, and standardize against National Bureau of Standards' standard sample No. 78 of known phosphorous content.

Moisture

29. Weigh 1.00 g. of the sample and heat to constant weight at a temperature not under 105 nor over 110 C. Record the loss in weight as moisture.

Loss on Ignition

30. Weigh 1.000 g. of the moisture-free (105 to 110 C.) sample and heat to constant weight over a blast lamp, or in an electric muffle furnace, at 900 to 1000 C. Record the loss in weight as the ignition loss.

Silica

31. (*a*) Weigh 1.0000 g. of the moisture-free (105 to 110 C.) sample into a platinum crucible which is free from any iron stain. Add 0.40 g. of anhydrous borax ($Na_2B_4O_7$) and 2.00 g. of Na_2CO_3. Mix well and fuse first at a low red heat, gradually increasing to the full temperature of a blast burner. Blast for 15 min. Dissolve the melt in diluted HCl (1:4) in an evaporating dish, add 2 to 3 ml. of diluted H_2SO_4 (1:1) (Note 1), and evaporate to dryness. Wash down the sides of the dish with 25 ml. of methyl alcohol (Note 2) saturated with HCl gas. Evaporate, add methyl alcohol solution, and evaporate again. Bake to dehydrate the SiO_2. Cool, add 15 ml. of HCl and 50 ml. of water, boil 1 to 2 min., and filter on a No. 40 Whatman or similar filter paper. Wash four to five times with hot diluted HCl (1:4), then seven to eight times with hot water. Reserve the paper containing the SiO_2 precipitate. Transfer the filtrate to the original dish and evaporate to dryness and bake. Add 15 ml. of HCl and 50 ml. of water, bring just to a boil, filter on a No. 42 Whatman or similar filter paper, and wash as before. Reserve the filtrate.

NOTE 1.—Diluted H_2SO_4 is used to prevent TiO_2 from hydrolyzing and precipitating with the SiO_2.

NOTE 2.—Methyl alcohol is used to eliminate traces of boron.

(*b*) Place the two filter papers containing the SiO_2 precipitate in a platinum crucible, ignite carefully until the paper is burned off, then heat at 1100 to 1200 C. for 10 to 15 min. Cool, weigh, and repeat heating at 1100 to 1200 C. until constant weight is obtained. Moisten the ignited precipitate with water, add HF slowly until the crucible is half-full, then add 5 drops of H_2SO_4 and evaporate to fumes. Cool, add 2 to 3 ml. of HF and 2 drops of H_2SO_4, and evaporate to dryness. Heat the crucible to bright redness and blast at 1100 to 1200 C. for 5 min. Cool, weigh, and repeat blasting until constant weight is

obtained. The loss in weight represents the SiO_2 content except for the small amount which is later recovered from the alumina precipitate.

Separation of Al_2O_3 and P_2O_5 from Fe_2O_3, TiO_2, CaO, and MgO

32. Fuse the residue from the HF evaporation (Section 31 (*b*)) with a little $K_2S_2O_7$ or $Na_2S_2O_7$, dissolve the melt in diluted HCl (1:4) and add to the filtrate from the SiO_2 precipitate which was reserved. Reduce the volume to about 75 ml. and nearly neutralize with NaOH (10 per cent). Slowly and while swirling constantly pour into a 250-ml. volumetric flask containing 100 ml. of NaOH (10 per cent) to which has been added 1 g. each of Na_2CO_3 and Na_2O_2 (Notes 1 and 2). Warm on a water bath for 1 hr. and cool to room temperature. Dilute with water to the mark, mix well, and let stand a few minutes. Filter off the precipitate on a filter paper which has been previously washed with NaOH (10 per cent) and dried, catching the filtrate in a dry beaker. Do not wash the precipitate. From the filtrate take a 100-ml. aliquot for the determination of Al_2O_3 (Section 36) and another 100-ml. aliquot for the determination of P_2O_5 (Section 35).

NOTE 1.—The Na_2CO_3 is used to precipitate calcium and magnesium along with iron and titanium.

NOTE 2.—The Na_2O_2 is used to oxidize any chromium present so that it may later be separated from the Al_2O_3.

Iron Oxide

33. Dissolve the precipitate on the filter paper and that adhering to the flask with hot diluted HCl (1:4). Adjust the volume to about 100 ml., add 5 g. of NH_4Cl, and heat to boiling. Add NH_4OH while stirring slowly until there is a slight excess. Again heat to boiling, filter hot, and wash five times with hot NH_4Cl (2 per cent). Place the paper containing the precipitate in the original beaker, add 15 ml. of HCl, stir to macerate the paper, dilute with hot water to 100-ml. volume, and precipitate with NH_4OH. Filter, and wash as before. Combine the two filtrates and reserve for the determination of CaO and MgO. Dissolve the precipitate in hot diluted HCl (1:4), and cool. Pour into a 100-ml. volumetric flask, dilute with water to the mark, and mix. Draw off exactly 5.0 ml. of the solution and reserve for the determination of TiO_2 (Section 34). Pour the remaining solution into a 250-ml. beaker and evaporate to dryness. Add 25 ml. of HCl (1:1), and heat to boiling. From this point proceed in accordance with the procedure described in Section 22 for the determination of Fe_2O_3 in the analysis of silica refractories.

Titania

34. Add to the 5.0-ml. portion previously reserved (Section 33) 10 ml. of H_2SO_4 (1:1) and evaporate to fumes. Dilute with 10 to 20 ml. of water, and cool. Pour into a 100-ml. volumetric flask, add a few drops of H_2O_2 (30 per cent), dilute to the mark, and mix. To a 100-ml. volumetric flask, add exactly 20.0 ml. of the standard TiO_2 solution and 10 ml. of H_2SO_4 (1:1). Add a few drops of H_2O_2 (30 per cent), dilute to the mark, and mix. Compare the colors either in Nessler tubes or in a suitable colorimeter.

Phosphorous Oxide

35. Acidify with HNO_3 the 100-ml. aliquot previously reserved (Section 32). Dilute to 200-ml. volume and precipitate the Al_2O_3 and P_2O_5 by adding a slight excess of NH_4OH solution. Filter, wash a few times with hot water, and dissolve the precipitate in 100 ml. of diluted HNO_3 (1:9). Transfer to a 300-ml. Erlenmeyer flask, heat to boiling and add a saturated solution of $KMnO_4$

until a pink color persists. Decolorize with a few drops of sulfurous acid, add 15 ml. of HNO_3, cool, adjust the volume to about 125 ml., and add 20 ml. of NH_4OH and 40 ml. of molybdate reagent. Shake for 10 min., let stand for 30 to 40 min., and filter. Wash the flask, paper, and precipitate at least ten times with KNO_3 solution (1 per cent). Return the paper and precipitate to the flask. Add an excess of standard NaOH solution and 25 ml. of water (both free from CO_2). Shake until the precipitate is dissolved and dilute to a 100-ml. volume. Add 2 to 3 drops of phenolphthalein (0.2 per cent), then titrate with standard HNO_3 to the disappearance of the pink color. Subtract from the original NaOH added the volume equivalent to the HNO_3 required to discharge the color. The difference gives the milliliters of NaOH equivalent to the P_2O_5 present. Calculate the percentage of P_2O_5.

Alumina[5a]

36. (*a*) Dilute the 100-ml. aliquot, previously reserved (Section 32), to a 250-ml. volume, make acid with HCl (1:1), and add 5 g. of NH_4Cl. Heat to boiling, add NH_4OH very slowly, while stirring constantly, until there is a slight excess as shown by methyl red. Boil 1 to 2 min., filter hot, and wash five to six times with hot NH_4Cl (2 per cent). Place the paper containing the precipitate in the original beaker, add 15 ml. of HCl, and, with the aid of a glass stirring rod, macerate the paper. Add boiling water to make up to a volume of about 250 ml. Repeat the precipitation with NH_4OH and filter as before. Wash thoroughly with hot NH_4Cl (2 per cent), using at least 250 ml. of wash solution.

(*b*) Place the paper containing the precipitate in a platinum crucible which has been previously weighed with its cover. Carefully burn off the paper, blast at not less than 1200 C. for 10 min., cool, and weigh. Repeat blasting and weighing until constant weight is obtained. The increase in weight is the Al_2O_3 and P_2O_5 plus a little SiO_2 which has escaped precipitation. To obtain the percentage of Al_2O_3, subtract the P_2O_5 (Section 35) and SiO_2 (Section 36 (*c*)).

(*c*) To determine the SiO_2, fuse the precipitate with about 5 g. of $K_2S_2O_7$ or $Na_2S_2O_7$. Dissolve the melt in warm water, add about 30 ml. of diluted H_2SO_4 (1:1) solution. Evaporate to copious fumes of H_2SO_4 and cool. Take up with water, filter, wash, ignite in a platinum crucible, and weigh. Treat the residue with 5 ml. of HF and 2 to 3 drops of H_2SO_4, evaporate to dryness, ignite, and weigh. The loss in weight is SiO_2. Add to the original silica determination.

Lime

37. Determine CaO in the filtrate from the Fe_2O_3 precipitate according to the method described for the determination of lime under analysis of fireclay refractories (Section 14).

Magnesia

38. Determine MgO by the method described for the determination of magnesia under analysis of fireclay refractories (Section 15).

Alkalies

39. Proceed as in the determination of alkalies under the analysis of fireclay refractories (Section 16) but with the following precautions:

(*a*) Fuse the sample at 1200 C. to obtain complete decomposition of the material.

(*b*) Cool the top of the crucible to prevent any loss of alkalies by volatilization. Cooling can be accomplished more

easily if a platinum crucible of the J. Lawrence Smith, long type is used.

MAGNESITE REFRACTORIES

Special Solutions Required

40. The following solutions will be required:

(*a*) *Hydrochloric Acid (2.5 per cent by volume).*

(*b*) *Potassium Permanganate (Approximately 0.5 N).*—Dissolve 16 g. of $KMnO_4$ in 1000 ml. of water.

(*c*) *Ammonium Chloride - Hydrochloric Acid Solution.*—Dissolve 50 g. of NH_4Cl in water, add 50 ml. of HCl (sp. gr. 1.19), and dilute to 1000 ml.

Preparation of Samples for Analysis

41. A 10-lb. sample carefully obtained after the manner of one of the approved methods of sampling shall be crushed to pass a No. 8 (2380-micron) sieve,[5] mixed thoroughly, and reduced by quartering to about 0.5 lb. This shall be crushed to pass a No. 20 (840-micron) sieve,[5] mixed, and quartered to about 50 g. This 50-g. sample shall then be ground in an agate mortar so that it will all pass a No. 100 (149-micron) sieve,[5] mixed thoroughly, and placed in an airtight container until analyzed, since finely ground, dead-burned magnesite gradually absorbs and fixes moisture and carbon dioxide.

Moisture

42. Weigh 1.00 g. of the sample and heat to constant weight at a temperature not under 105 nor over 110 C. Record the loss in weight as moisture.

Loss on Ignition

43. Weigh 1.000 g. of the moisture-free (105 to 110 C.) sample and heat to constant weight over a blast lamp, or in an electric muffle furnace, at 900 to 1000 C. Record the loss in weight as the ignition loss.

Silica

44. Transfer 1.0000 g. of the moisture-free (105 to 110 C.) sample to a 210-ml. casserole. Moisten the solids with a few milliliters of water, slowly add 20 ml. of HCl, and cover the casserole. While covered, digest on the hot plate until solution is complete and all gritty particles have disappeared, breaking up any solid cake from time to time with a stirring rod. Uncover, add 8 ml. of perchloric acid, $HClO_4$ (60 to 70 per cent), and evaporate to heavy white fumes of $HClO_4$. Cover and boil so that the acid refluxes for 10 to 15 min. Remove from the hot plate, cool, wet with a few milliliters of water and 5 ml. of HCl, warm for a few minutes on the hot plate, add 50 ml. of hot water, heat to approximately boiling, and filter through a 9-cm. rapid filter. Wash the paper and precipitate ten times with a hot HCl solution (2.5 per cent), then three times with hot water. Return the filtrate to the casserole in which the first evaporation was made, add 2 ml. of $HClO_4$, and evaporate to fumes on the hot plate, boiling as before. Cool, take up in acid and water, filter, and wash as before. Reserve the filtrate. Place both papers and precipitates in a tared platinum crucible. Dry, then burn off the papers and ignite to constant weight in the muffle or over a moderate blast. Cool in a desiccator and weigh as impure SiO_2. Add two drops of diluted H_2SO_4 (1:1) and 1 ml. of HF to the impure SiO_2 in the crucible. Digest for 5 to 10 min., covered, on the hot plate, then remove the cover and evaporate to dryness. Fume off the H_2SO_4 over a moderate heat, and ignite or blast for a few minutes. Cool in a desiccator, and weigh again. Subtract the weight of the

crucible and residue from the weight of the crucible and impure SiO_2; the difference is the corrected SiO_2. Fuse the residue in the crucible by heating gently with a small piece of $K_2S_2O_7$ or $Na_2S_2O_7$ about the size of a pea, cool, dissolve in water, and add to the reserved filtrate from the silica determination.

Iron and Aluminum Oxides

45. Add to the filtrate from the silica determination (Section 44), which should be in a 400-ml. beaker, 5 g. of NH_4Cl. Dilute from 150 to 200 ml., add three drops of methyl red (0.1 per cent), heat to boiling. Add NH_4OH (1:1) slowly, finally drop by drop until the solution is just alkaline to the indicator. Boil for 1 or 2 min. and filter through a 9-cm. rapid filter. Do not wash. Reserve the filtrate. Transfer the paper and precipitate to the beaker in which the precipitation was made, add 50 ml. of HCl (1:4), and digest covered on the hot plate, shaking frequently until the precipitate is dissolved and the paper well macerated. Dilute, add methyl red, reprecipitate with NH_4OH (1:1), boil, and filter, exactly as before. Add this second filtrate to the first filtrate for the subsequent determination of lime (Section 48 (*a*)). Swab the beaker and rod and wash the paper and precipitate with NH_4Cl solution (2 per cent). Dry, then ignite the paper and precipitate in a tared platinum crucible at 1000 to 1100 C. for 1 hr. with access of air. Cool in a desiccator, and weigh as R_2O_3 which is mainly the Fe_2O_3 and Al_2O_3.

Iron Oxides

46. Weigh 2.00 g. of the moisture-free (105 to 110 C.) sample into a 150-ml. beaker, and cover. Dissolve by slowly adding HCl, keeping the beaker on the hot plate. Finally, add about 5 ml. of HCl in excess. Heat to gentle boiling until the siliceous residue undissolved appears iron-free. Filter, and fuse the residue with a very little $K_2S_2O_7$ or $Na_2S_2O_7$ in a porcelain or vitreous silica crucible to avoid introducing platinum. Dissolve the fused material and add to the filtrate. Add a few drops of a strong solution of $KMnO_4$ (about 0.5 *N*) to oxidize any organic matter that may be present. Boil. When the excess of $KMnO_4$ is decomposed and chlorine fumes have disappeared, reduce the iron by adding $SnCl_2$ solution drop by drop from a pipette while swirling the beaker constantly until the solution is colorless, then add 1 drop in excess. Cool quickly in running water, then add at one stroke 15 ml. of saturated $HgCl_2$ solution. Allow to stand for 3 min., transfer with washing to a 600-ml. beaker containing 300 ml. of cold distilled water and 25 ml. of $MnSO_4$ solution. Titrate with standard 0.1 *N* $KMnO_4$ solution, added very slowly while stirring constantly until a permanent pink end point is obtained.

Alumina

47. Subtract the calculated weight of iron oxide (Section 46) from the weight of R_2O_3 (Section 45). The remainder is the weight of the Al_2O_3 plus small amounts of oxides of any other elements that were precipitated (Note).

NOTE.—These may include P_2O_5, TiO_2 and small amounts of SiO_2, but they are present in such small amounts as to be disregarded in the complete analysis of magnesite refractories.

Lime

48. (*a*) *Method A: When MgO is to be Determined Directly.*—Acidify with several milliliters of HCl (50 per cent) the combined filtrate from the R_2O_3 precipitation (Section 45) and evaporate to a volume of about 250 ml. Heat to incipient boiling, add 25 ml. of a saturated $(NH_4)_2C_2O_4$ solution (about 4 per cent) and NH_4OH until slightly alkaline. Stir thoroughly and allow the precipitate

to settle out, keeping the solution warm for 3 to 4 hr. but not boiling. Filter and wash five times with cold water. Save the filtrate. Dissolve the washed oxalate precipitate with 50 ml. of diluted HCl (1:1), dilute to 250 ml. and precipitate as before. Wash the beaker, precipitate, and paper with cold water until $(NH_4)_2C_2O_4$ is removed. Avoid excessive washing. Combine the filtrates for the determination of MgO (Section 49). To the beaker used for the precipitation, add 150 ml. of H_2SO_4 (5 per cent), then introduce the paper containing the precipitate. Heat to almost boiling and titrate with 0.1 *N* $KMnO_4$. A blank should be previously determined for the effect of the paper.

A small part of the CaO occasionally escapes the oxalate precipitation and comes down subsequently with the MgO. To the CaO precipitated by the oxalate should accordingly be added that found in the MgO.

(*b*) *Method B: When MgO is to be Determined by Difference.*[8]—Weigh 2.50 g. of the moisture-free (105 to 110 C.) sample into a 250-ml. beaker, add 10 ml. of water, cover, slowly add HCl until dissolved, stirring frequently and avoiding excessive boiling. Then add about 5 ml. of HCl in excess. Evaporate on a hot plate until very thick and syrupy. At this stage crusts will be forming on the surface and a drop of material placed on the wall of the beaker will immediately solidify. Remove the beaker from the hot plate and allow to partially cool. Add 5 ml. of H_2SO_4 (10 per cent). Cover with a watch glass, heat on a hot plate until all soluble matter is dissolved. Cool slightly, but not until solids separate. Add 50 ml. of alcohol, stir thoroughly, and heat just to boiling on a hot plate. Filter with suction through a Gooch crucible prepared with a moderately thin asbestos mat. If the SiO_2 is less than 3.5 per cent, filter through paper. Rinse the beaker twice with alcohol, pouring the washings through the crucible. Drain under suction. Remove the crucible, scrape out the mat with a glass rod into the beaker in which the precipitation of sulfate was made, wash the crucible clean with a hot NH_4Cl - HCl solution, using about 35 ml. If the SiO_2 is high (over 6 per cent) it is advisable to filter it off at this point before precipitating the lime. Dilute to about 150 ml. with hot water, make alkaline with NH_4OH, heat to boiling, and precipitate the calcium by slowly adding 15 ml. of a saturated solution of $(NH_4)_2C_2O_4$. Digest on the hot plate just below boiling for 30 min. Filter on a 9-cm. paper, wash with cold water until free from oxalate, testing final washing with a drop of $KMnO_4$ after acidification. Transfer the paper and precipitate to the original beaker, dissolve with 150 ml. of H_2SO_4 (5 per cent), and titrate as in Method A (Paragraph (*a*)). Correct for a blank on the filter paper.

Magnesia[5a]

49. (*a*) Acidify with several milliliters of HCl (50 per cent) the combined filtrates reserved during the determination of CaO (Section 48 (*a*)). Dilute to 500 ml. in a calibrated flask and take a 50 ml. ($\frac{1}{10}$) aliquot portion. Since a 1-g. sample was originally used, this will yield aliquot portions containing between 0.08 to 0.09 g. of MgO. Dilute to 250 ml. and add 2 to 3 g. of diammonium phosphate ($(NH_4)_2HPO_4$), stir until dissolved. Add NH_4OH slowly until alkaline and then 30 ml. of NH_4OH in excess. Allow the solution to stand for at least 4 hr., preferably overnight if the total amount of solution exceeds 400 ml. in

[8] In this specific procedure very much less lime escapes precipitation and thus the magnesia "by difference" is not subject to this plus error. The procedure further has the advantage that an individual lime determination may be made without separating the other usual constituents.

volume. Filter, wash with diluted NH_4OH (5 per cent). Dissolve from the paper with hot HCl (1:1) and reprecipitate by adding 0.1 g. of $(NH_4)_2HPO_4$, diluting, rendering ammoniacal, and letting stand as before. After filtering and washing as before, char the paper and burn off the carbon below 900 C., then ignite to constant weight in an electric muffle furnace at about 1100 C. The ignited material consists of magnesium pyrophosphate, $Mg_2P_2O_7$, as well as some of the CaO and MnO. Correction may be made for these as follows:

(*b*) Dissolve the ignited pyrophosphate in a little diluted H_2SO_4 and add enough absolute alcohol to make up 90 to 95 per cent of the final volume. Any calcium present will settle out as $CaSO_4$. Filter, wash with alcohol, and dissolve the precipitate in hot diluted HCl. Precipitate with oxalate and titrate with permanganate. Add this CaO to that previously found. Calculate the CaO to tricalcium phosphate, $Ca_3(PO_4)_2$, by multiplying by the factor 1.845 and deduct this amount from the weight of the $Mg_2P_2O_7$. The correction to the first calcium precipitate is ten times the weight of the CaO precipitated as sulfate.

(*c*) The manganese which contaminates the $Mg_2P_2O_7$ is determined in the alcoholic filtrate from the $CaSO_4$. Evaporate this filtrate until strong fumes are evolved and all organic matter destroyed. Cool, dissolve the residue in 25 ml. of HNO_3 (30 per cent) and determine the manganese by the bismuthate method, as described in Section 50, omitting the Na_2CO_3 fusion. Calculate any manganese found to $Mn_2P_2O_7$ by multiplying by the factor 2.585 and deduct this weight from the $Mg_2P_2O_7$.

Manganese as MnO

50. Mix intimately 1.0 to 5.0 g. of the moisture-free (105 to 110 C.) sample (depending upon the amount of manganese expected) with 0.5 to 2.5 g. of anhydrous Na_2CO_3 and ignite in a platinum crucible for 15 min. at about 1000 C. Dissolve the sintered melt in 50 ml. of HNO_3 (30 per cent), and if there is any evidence of brown hydrated MnO_2 add sulfurous acid drop by drop. Boil the solution, filter if necessary, cool to room temperature or lower, and add 2 to 3 g. of sodium bismuthate. Agitate the solution for 1 min. and filter through asbestos (Note). Wash with HNO_3 (3 per cent) until the residue is free from permanganic acid, as determined by the absence of the pink color in the washings. Titrate, at once, the permanganic acid formed, with standard sodium arsenite (1 ml. = 0.0002 g. of Mn). The end point is the disappearance of the pink color. The factor for converting Mn to MnO is 1.291.

NOTE.—A good grade of asbestos, acid washed, and specially prepared for Gooch crucibles, should be used.

CHROME ORE AND CHROME REFRACTORIES

(*Including Chrome-Magnesite Refractories*)

NOTE.—This method is not intended to cover electrically fused aluminous refractories containing chrome ore.

Reagents

51. (*a*) *Ammonium Hydroxide* (*2.5 per cent by volume*).

(*b*) *Ammonium Hydroxide* (*10 per cent by volume*).

(*c*) *Ammonium Hydroxide* (*25 per cent by volume*).

(*d*) *Hydrochloric Acid* (*5 per cent by volume*).

(*e*) *Hydrochloric Acid* (*10 per cent by volume*).

(*f*) *Phosphoric Acid*, H_3PO_4 (*sp. gr. 1.71*).

(*g*) *Ammonium Chloride Solution* (*1 per cent*).—Dissolve 1 g. of NH_4Cl in 100 ml. of water.

(*h*) *Ammonium Persulfate Solution.*—Dissolve 25 g. of $(NH_4)_2S_2O_8$ in 80 ml. of water.

(*i*) *Standard Ferrous Ammonium Sulfate Solution (0.2 N).*—Dissolve 78.4 g. of $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$ in 1 liter of water (Note). Standardize against 0.2 *N* $KMnO_4$. This standardization must be made each day the solution is used, as it gradually weakens due to oxidation.

NOTE.—C.P. ferrous ammonium sulfate crystals may be used instead of the standard solution.

(*j*) *Standard Potassium Permanganate (0.2 N).*—Dissolve 6.5 g. of $KMnO_4$ in 1 liter of water. Standardize against the National Bureau of Standards' standard sample 40*c* of sodium oxalate.

(*k*) *Potassium Permanganate Solution (2.5 per cent).*—Dissolve 2.5 g. of $KMnO_4$ in 100 ml. of water.

(*l*) *Silver Nitrate Solution (0.5 per cent).*—Dissolve 0.5 g. of $AgNO_3$ in 100 ml. of water.

(*m*) *Sodium Chloride Solution (10 per cent).*—Dissolve 10 g. of NaCl in 100 ml. of water.

(*n*) *Ortho-Phenanthroline Indicator (Ferroin).*

Preparation of Samples for Analysis

52. The 50-g. sample referred to in Section 3 shall be ground so that it will all pass a No. 200 (74-micron) sieve.[5]

Moisture

53. Weigh 1.00 g. of the sample and heat to constant weight at a temperature not under 105 nor over 110 C. Record the loss in weight as moisture.

Loss on Ignition

54. Weigh 1.000 g. of the moisture-free (105 to 110 C.) sample and heat to constant weight over a blast lamp, or in an electric muffle furnace, at 900 to 1000 C. Record the loss in weight as the ignition loss.

Chromium Oxide

55. (*a*) Transfer 0.5000 g. of the moisture-free (105 to 110 C.) sample to a 30-ml. pure iron crucible (Note 1). Mix with about 8 g. of dry Na_2O_2, cover with an iron lid, and heat over a very low flame (Note 2). After the charge is melted, increase the temperature slowly to a medium red (650 to 750 C.), and continue heating for 3 to 5 min. Do not continue heating longer than this, because attack of the flux is quite rapid at red heat or above. After removing the crucible from the heat, rotate to spread the contents over the crucible walls, and cool. Place crucible and lid in a covered 600-ml. beaker, and add 250 ml. of cold water. After reaction has stopped and the melt is completely dissolved, remove the crucible and lid, and wash them thoroughly (Note 3).

NOTE 1.—Ordinary iron crucibles, which may contain significant amounts of chromium, should be avoided. Crucibles made of ingot iron are satisfactory.

NOTE 2.—If about 0.2 g. of very finely pulverized sugar charcoal is mixed with the Na_2O_2, only about 5 g. of the peroxide is required. Not more than 0.2 g. of sugar charcoal is recommended in order to avoid the possibility of explosion. After heating for about 30 sec., ignition of the sugar charcoal takes place, and the crucible will suddenly become a dull red on the outside. The total time required to complete the fusion is about 2 min. By thus shortening the time for fusion and contact with the flux, the life of the crucible is extended.

NOTE 3.—If sugar charcoal is used, it is advisable to add 1 to 2 g. of Na_2O_2 at this point.

(*b*) Boil for 10 min., or digest at 80 to 90 C. for 30 to 40 min., stirring occasionally to decompose the excess Na_2O_2. Cool, and add 60 ml. of H_2SO_4 (1:1) and 5 ml. of HNO_3. Boil until the iron scale from the crucible is dis-

solved. Add 20 to 25 ml. of $AgNO_3$ (0.5 per cent), 1 to 2 drops of $KMnO_4$ (2.5 per cent), and 10 to 15 ml. of $(NH_4)_2S_2O_8$ solution. Boil for 5 min. Add 20 ml. of NaCl (10 per cent) and boil for 5 to 10 min. after the permanganate or MnO_2 has completely disappeared. Cool to room temperature, and add 3 ml. of H_3PO_4.

(*c*) Now add a measured excess of ferrous ammonium sulfate, either as c.p. crystals or as a standard solution. If the crystals are used, add exactly 5 g. and stir until completely dissolved. If a solution is used, add from a burette the standard 0.2 *N* solution with 5 ml. in excess. The chromium will thus be reduced to the trivalent state and will change the color of the solution from amber to a bright green. Add two drops of ortho-phenanthroline (Ferroin) as an indicator. (The solution will become turbid and pink in color.) Titrate the ferrous ammonium sulfate, in excess of that required to reduce the chromium, with 0.2 *N* $KMnO_4$. The end point is reached when one drop of the standard $KMnO_4$ solution causes the turbidity to disappear and the solution to become clear green in color. Designate the first titration in either case as T_1. If ferrous ammonium sulfate crystals were used for reduction, titrate 5 g. of the crystals dissolved in H_2SO_4 (5 per cent) with the 0.2 *N* $KMnO_4$ solution. Designate the second titration as T_2. If the standard ferrous ammonium sulfate solution was used, T_2 is the milliliters of 0.2 *N* $KMnO_4$ equivalent to the total volume of 0.2 *N* ferrous ammonium sulfate originally added, including the 5 ml. excess. In either case, $T_2 - T_1$ then equals the milliliters of 0.2 *N* $KMnO_4$ equivalent to the weight of ferrous ammonium sulfate required to reduce the chromium in the sample. Calculate the percentage of chromium oxide, as follows:

$$Cr_2O_3, \text{ per cent} = \frac{(T_2 - T_1) \times N \text{ of } KMnO_4 \times 0.02534}{W} \times 100$$

where:

0.02534 = Cr_2O_3 equivalent of the $KMnO_4$, and

W = weight of the sample in grams.

Titania and Ferrous Oxide

56. (*a*) Transfer 0.5000 g. of the moisture-free (105 to 110 C.) sample to a 30-ml. nickel crucible. Mix with 2 to 3 g. (Note) of dry Na_2O_2, cover with lid, and fuse as described in Section 55.

NOTE.—The use of only 2 to 3 g. of Na_2O_2 reduces the amount of nickel dissolved which might interfere with the subsequent colorimetric determination of TiO_2. The small amount of nickel actually dissolved is entirely removed by the double NH_4OH precipitation.

(*b*) Take up the fusion in about 250 ml. of cold water. After reaction has stopped and the soluble constituents of the melt have completely dissolved, remove the crucible and cover and wash thoroughly. Boil for 5 min. Filter the iron and titanium oxides, and wash 10 times with hot water. Dissolve the precipitate from the paper with diluted HCl (1:1), and precipitate with NH_4OH in excess. Filter, and wash thoroughly with hot water. Again dissolve with HCl (1:1) and reprecipitate with excess NH_4OH, filter, and wash. Finally, dissolve the precipitate with hot diluted H_2SO_4 (10 per cent), cool, add several drops of H_2O_2, and dilute to 250 ml.

Titania

NOTE.—This determination is optional, since it is made only infrequently.

57. Take a 100-ml. aliquot portion from the 250-ml. acid solution (Section 56) and determine the TiO_2 colorimetrically by placing the solution in a 100-ml. Nessler tube (Note) and comparing it with the color of an appropriate

amount of the standard TiO_2 solution in another Nessler tube. Both the solution of the sample and the reference standard solution shall be cooled to room temperature before making the comparison. Dilute the reference standard with a measured amount of water from a burette until the color is matched. From the amount of water added, calculate the percentage of TiO_2 in the sample.

NOTE.—If preferred, any standard colorimeter may be used instead of the Nessler tubes.

Ferrous Oxide

58. (*a*) Use the remaining 150-ml. portion of the acid solution (Section 56), but boil off the H_2O_2; or, if TiO_2 is not to be determined, use the entire 250-ml. of solution (without adding H_2O_2).

NOTE.—It is equally satisfactory to add the 100-ml. aliquot portion used for the TiO_2 determination in Section 57 to the remaining 150 ml. in order to obtain the advantage in accuracy of using the entire 0.5-g. original sample.

(*b*) Evaporate to 100 ml. or less, add 25 ml. of diluted HCl (1:1), and heat to boiling. Reduce the iron by adding $SnCl_2$ solution drop by drop from a pipette, while swirling the beaker constantly, until the solution is colorless. Then add one drop in excess. Cool quickly in running water, then add at one stroke 15 ml. of saturated $HgCl_2$ solution. Allow to stand for 3 min.; then transfer with washing to a 600-ml. or 1000-ml. beaker containing 300 ml. of cold distilled water and 25 ml. of the $MnSO_4$ solution. Titrate with standard 0.04 *N* $KMnO_4$ solution, added very slowly while stirring constantly, until a permanent pink end point is obtained. A blank should also be determined. Calculate the iron to FeO.

Silica

59. Fuse 0.5000 g. of the dried (105 to 110 C.) sample in approximately 10 g. of fused $K_2S_2O_7$ or $Na_2S_2O_7$ in a vitreous silica or porcelain crucible. The usual precautions of a pyrosulfate fusion should be observed; that is, the flame should be turned very low at the start so that the pyrosulfate just melts, then the flame increased so that the pyrosulfate remains in a liquid condition, and finally the temperature gradually raised until the crucible reaches a dull red heat. The object of the slow heating is to retain the H_2SO_4, which is the effective part of the flux. Excessive fuming is to be avoided because it may result in "crawling" of the melt up the sides of the crucible, producing the difficultly soluble anhydrous $Cr_2(SO_4)_3$. The most refractory materials should be thoroughly fused in 1 to 1½ hr. Remove the crucible from the burner, and allow to cool in the air. The pyrosulfate melt will shrink from the crucible, and the main mass may be removed easily in one cake. Dissolve the cake and the small portion retained on the crucible walls in 200 ml. of hot diluted HCl (1:1), boiling until the solution acquires a clear, bright green color. Evaporate to dryness, and bake at not over 120 C. until free from fumes of HCl, which will require about 1 hr. Moisten with hot diluted HCl (1:1), then add about 25 ml. more acid, warm until all salts are in solution, and filter off the SiO_2. Evaporate the filtrate to dryness, bake, and filter again. Wash the SiO_2 thoroughly with diluted HCl (5 per cent). Ignite in a tared platinum crucible to constant weight in an electric muffle furnace or over a moderate blast, and weigh. Add two drops of diluted H_2SO_4 (1:1) and about 10 ml. of HF to the crucible. Evaporate, ignite, and weigh as before. The difference represents the amount of SiO_2 present in the sample. Should there be any appreciable residue left in the crucible, fuse with a small amount of pyrosulfate and add to the filtrate from the SiO_2.

NOTE.—Decomposition by means of perchloric acid is permissible where it has been found that the particular chrome ore or burned refractory is amenable to such treatment. High-alumina ores and hard burned refractories are generally difficult to get completely into solution with perchloric acid.[9]

Alumina

60. (*a*) *Method A: R_2O_3 Precipitated with NH_4OH.*—Combine the filtrates from the silica determination (Section 59) and dilute to exactly 500 ml. in a graduated flask. Take a 300-ml. aliquot portion and add 15 g. of NH_4Cl and 3 drops of methyl red solution (0.1 per cent). Heat the solution almost to boiling, and add slowly NH_4OH (1:1) until the indicator has changed to a yellow color. Boil for 1 or 2 min. to remove excess ammonia, and allow the precipitate to settle. Filter through an 11-cm. rapid filter paper. Do not wash. Reserve the filtrate *A* for the determination of CaO and MgO (Section 61). Transfer the paper and precipitate to the beaker in which the precipitation was made, add 50 ml. of HCl (20 per cent), and digest covered on the hot plate, shaking frequently until the precipitate is dissolved and the paper well macerated. Dilute, add methyl red, reprecipitate with NH_4OH (1:1), boil, and filter, exactly as before. Add this second filtrate *B* to the first filtrate for the subsequent determination of CaO and MgO (Section 61). Swab the beaker and rod, and wash the paper and precipitate with hot NH_4Cl (2 per cent). Place the paper and precipitate in a tared platinum crucible and dry. Carefully burn off the paper, and then blast at 1200 C. to constant weight (30 min. is generally sufficient). Cool in a desiccator, and weigh with the crucible covered by the lid. The ignited precipitate consists of Fe_2O_3, Al_2O_3, Cr_2O_3, and TiO_2. To obtain the percentage of Al_2O_3, subtract from the weight of ignited precipitate the FeO (Section 58) calculated to Fe_2O_3, plus the TiO_2 (Section 57) and the Cr_2O_3 (Section 55).

(*b*) *Method B (Optional): R_2O_3 Precipitated with Urea.*—Dilute the entire combined filtrates from the silica determination (Section 59) to about 400 ml., preferably in a 600-ml. beaker. Add 15 g. of NH_4Cl, then add NH_4OH slowly until a slight permanent cloudiness appears. Clear the solution by adding diluted HCl (1:1) drop by drop and then 2 to 3 drops in excess. Now add 6 g. of urea (Note). Bring to a boil and continue boiling gently on the back of a hot plate for 2 hr. after the first opalescence appears. The decomposition of the urea causes a gradual increase in the pH of the solution, which is uniform throughout, and precipitates the R_2O_3 group as the dense basic sulfates. The final pH value of the solution is about the same as when using NH_4OH and the proper indicator. Remove from the hot plate, and allow the precipitate to settle, keeping the solution warm. Filter through two dense filter papers folded together, and transfer the bulk of the precipitate to the papers. The basic sulfate precipitate occupies only about one third of the volume of the equivalent hydroxide and is, accordingly, easily transferred and washed. For transferring the precipitate, use NH_4Cl solution (1 per cent) made just alkaline to methyl red indicator with NH_4OH. The small amount of precipitate adhering to the sides of the beaker may be removed by thorough scrubbing with a rubber policeman, or better, by dissolving with diluted HCl (5 per cent)

[9] For a description of a procedure using perchloric acid, see T. R. Cunningham and T. R. McNeil, "Analysis of Chrome Ores," *Industrial and Engr. Chemistry*, Anal. Ed., Vol. 1, p. 70 (1929).

directed against the side of the beaker from a wash bottle. Heat gently, add one drop of methyl red indicator, and then diluted NH_4OH (10 per cent) until just alkaline. Transfer the small amount of precipitated hydroxide to the filter paper holding the basic sulfate precipitate, using the NH_4Cl solution (1 per cent) referred to above. Scrub the beaker, and then wash the combined precipitates 10 times with the above solution. Reserve the filtrate for the determination of CaO and MgO (Section 61), and complete the procedure as described in Paragraph (*a*).

NOTE.—The precipitate obtained with urea is fine grained and much smaller in volume than the gelatinous hydroxides obtained with NH_4OH. This permits rapid filtering and more thorough washing.[10]

Lime

61. (*a*) Make the combined filtrates *A* and *B* from Section 60 (*a*), or the filtrate from Section 60 (*b*), slightly acid with HCl, evaporate to a volume of approximately 150 ml., and cool. Add 20 ml. of diammonium phosphate ($(NH_4)_2HPO_4$) solution (10 per cent), and slowly introduce NH_4OH drop by drop, while stirring vigorously, until the solution is ammoniacal and a crystalline precipitate appears. Add 15 ml. of NH_4OH, stir thoroughly, and allow to stand overnight at room temperature. Filter the solution on a 9-cm. filter paper, and wash the precipitate three or four times by decantation with cold NH_4OH (2.5 per cent). Pour 25 ml. of HCl (1:1) through the filter paper, collecting the filtrate in the original beaker containing the bulk of the precipitate. Wash the paper thoroughly with HCl (5 per cent). Dilute the solution to a volume of 150 ml. with cold water, add 3 ml. of $(NH_4)_2HPO_4$ (10 per cent), and repeat the precipitation. Allow to stand several hours. When cool, filter, wash 10 to 12 times with cold NH_4OH (2.5 per cent), and ignite in a tared platinum crucible, first at a dull red heat until the carbon has been removed, and finally to constant weight at about 1100 C. (20 to 30 min. is generally sufficient). The pyrophosphates thus obtained contain all the calcium, magnesium, and any manganese present.

(*b*) Dissolve the ignited pyrophosphates in 10 ml. of H_2SO_4 (1:1), and evaporate to fumes of SO_3. Cool, and add 5 ml. of water and enough absolute ethyl or methyl alcohol to constitute 90 to 95 per cent of the total volume of liquids present. Stir vigorously for several minutes. Allow the $CaSO_4$ precipitate to settle for 2 or 3 hr., or overnight if preferred, filter on a 9-cm. paper, and wash free of H_2PO_4 with ethyl alcohol (80 per cent). Dissolve the precipitate from the paper with HCl (10 per cent), and wash with about 25 ml. of the acid. Dilute to about 150 ml. with hot water, make alkaline with NH_4OH, heat to boiling, and precipitate the calcium by slowly adding 10 to 15 ml. of a saturated solution of ammonium oxalate. Digest on the hot plate just below boiling for 30 min. Filter on a 9-cm. paper, and wash with cold water until free from oxalate. Transfer the paper and precipitate to the original beaker, and dissolve with 150 ml. of H_2SO_4 (5 per cent). Heat almost to boiling, and titrate with 0.04 *N* $KMnO_4$.

Manganese as MnO

62. (*a*) Evaporate the alcoholic filtrate from the $CaSO_4$ (Section 61) until strong fumes of SO_3 are evolved and all organic matter is destroyed. After the

[10] For a description of an investigation of this procedure, see Hobart H. Willard and Ning Kang Tang, "Quantitative Determination of Aluminum by Precipitation with Urea," *Industrial and Engr. Chemistry*, Anal. Ed., Vol. 9, pp. 357 to 363 (1937)

solution has cooled, dissolve the residue in 25 ml. of HNO_3 (30 per cent). The oxidation of the manganese from this point may be effected by either of the following two methods:

Persulfate Method.—Add 75 ml. of water, 6 ml. of $AgNO_3$ solution (0.5 per cent), and 10 ml. of $(NH_4)_2S_2O_8$ solution. Boil for 1 min. and cool to room temperature.

Bismuthate Method.—If there is any evidence of brown hydrated MnO_2 after solution in the HNO_3, add H_2SO_3 drop by drop. Boil the solution, filter if necessary, cool to room temperature or lower, and add 2 to 3 g. of sodium bismuthate. Agitate the solution for 1 min., and filter through asbestos (Note). Wash with HNO_3 (3 per cent) until the residue is free from permanganic acid, as determined by the absence of the pink color in the washings.

NOTE.—A good grade of asbestos, acid washed and specially prepared for Gooch crucibles, should be used.

(*b*) Titrate at once with standard sodium arsenite (1 ml. is equivalent to 0.0002 g. of Mn), the permanganic acid formed from either the persulfate or the bismuthate method (Paragraph (*a*)). The end point is the disappearance of the pink color. The factor for converting Mn to MnO is 1.291.

Magnesia

63. Calculate the CaO obtained in Section 61 to $Ca_3(PO_4)_2$ by multiplying by the factor 1.845, and the MnO determined in Section 62 to $Mn_2P_2O_7$ by multiplying by the factor 2.001. Deduct the sum of these two phosphates from the weight of the combined phosphates of calcium, manganese, and magnesium in Section 61. The difference is the weight of $Mg_2P_2O_7$. The factor for converting $Mg_2P_2O_7$ to MgO is 0.362.

Standard Method of Test for

PYROMETRIC CONE EQUIVALENT (P.C.E.) OF REFRACTORY MATERIALS[1]

A.S.T.M. Designation: C 24 - 42

ADOPTED, 1920; REVISED, 1928, 1931, 1933, 1935, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 24; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers a procedure for determining the pyrometric cone equivalent (P.C.E.) of fire clay, fireclay brick, and silica cement by comparison of test cones with Standard Pyrometric Cones under the conditions herein prescribed.

Preparation of Sample

2. (*a*) *Clay or Brick.*—The entire sample of fire clay or fireclay brick, in case the amount is small, shall be crushed by means of rolls or a jaw crusher so as to produce a particle size not larger than $\frac{1}{4}$ in. In case the amount is large, a representative sample obtained by approved methods shall be so treated. The sample shall then be mixed thoroughly and the amount reduced to about 250 g. (0.5 lb.) by quartering. Any magnetic material introduced by crushing or grinding shall be removed by means of a magnet. This portion shall then be ground in an agate, porcelain, or hard steel mortar and the amount reduced again by quartering. The final size of the sample shall be 50 g. and the fineness such that it will pass a No. 70 (210-micron) A.S.T.M. sieve[3] (equivalent to mesh No. 65 of the Tyler standard series). In order to avoid excessive reduction of fines, they shall be removed frequently during the process of reduction by throwing the sample on the sieve and continuing the grinding of the coarser particles until all the sample passes through the sieve.

(*b*) *Silica Cements.*—In the case of silica cements, the sample obtained by approved methods shall be tested as received without grinding or other treatment.

NOTE.—For the purpose of this test, silica cement is understood to be the usual finely ground mixture of quartzite, silica brick, and fire clay of various proportions, and does not include materials sold under the name of high-temperature mortars.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1919 to 1920. Editorially revised in 1943.

[3] Detailed requirements for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

Preparation of Test Cones

3. (*a*) The dried sample shall be thoroughly mixed and after the addition of sufficient dextrine, glue, gum tragacanth, or other alkali-free organic binder and water, shall be formed in a truncated trigonal pyramid with its base at a small angle to the trigonal axis, and of the following dimensions: Over-all height (between planes perpendicular to the trigonal axis) $1\frac{1}{8}$ in.; length of side of the truncated tip, $\frac{1}{32}$ in.; length of the two longer sides of the base, $\frac{9}{32}$ in.; base at an external angle of 82 deg. to one face and perpendicular to the symmetry plane through the opposite edge of the pyramid.

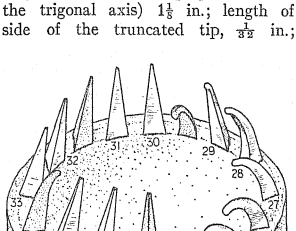

FIG. 1.—Method of Mounting Test Cones and Appearance After Testing.

(*b*) When dry the test cones may be subjected, when necessary, to a preliminary burn at a temperature not exceeding 2370 F. (1300 C.) for the purpose of sintering them to a firm condition to permit handling.

Mounting

4. The test cones shall be mounted on plaques of refractory material of such a composition as will not affect the fusibility of the cones.[4] They shall be mounted with the base embedded approximately 3 mm. (0.12 in.) in the plaque and the face of one side inclined at an angle of 82 deg. with the horizontal. The arrangement of the test cones with respect to the Standard Pyrometric Cones shall be substantially as shown in Fig. 1, that is, alternating the test cones with the Standard Pyrometric Cones in so far as is practical (Note). The plaque may be any convenient size and shape and may be biscuited before using, if desired.

NOTE.—The number of cones and their mounting so as to face inward as shown in Fig. 1 is typical for gas-fired furnaces of relatively large dimensions and gases moving at high velocity. The practical bore of the muffle tubes in most electric furnaces does not permit cone pats of this size. The static atmosphere prevailing permits the cones being mounted to face outward, if so desired.

Heating

5. (*a*) The heating shall be carried out in a suitable furnace at a rate to conform to the following requirements:

To reach cone No. 20	45 min.
Time interval to:	
Cone No. 23	20 min.
Cone No. 26	6 min.
Cone No. 27	4 min.
Cone No. 28	4 min.
Cone No. 29	10 min.
Cone No. 30	4 min.
Cone No. 31	12 min.
Cone No. 32	8 min.
Cone No. 32½	9 min.
Cone No. 33	9 min.
Cone No. 34	6 min.
Cone No. 35	10 min.
Cone No. 36	10 min.
Cone No. 37	4 min.
Cone No. 38	6 min.

NOTE.—At 1830 F. (1000 C.) the old cone pat may be removed and a new one put in without cooling the furnace to below red heat.

(*b*) That type of furnace in which a neutral or oxidizing atmosphere may be maintained is to be preferred. Exces-

[4] A mixture of equal parts of a highly refractory clay, such as a good grade of china clay and fused alumina, that will pass a No. 100 (149-micron) A.S.T.M. sieve (equivalent to mesh No. 100 of the Tyler standard series) has been found satisfactory.

sive reducing conditions should be avoided. Care should be taken that the flame does not strike directly against the cone or cone plaque. The furnace should be tested at intervals for the determination of the uniformity of the distribution of the heat.

Pyrometric Cone Equivalent

6. (*a*) The softening of the cone will be indicated by the top bending over and the tip touching the plaque. The bloating, squatting, or unequal fusion of small constituent particles should always be reported. The Pyrometric Cone Equivalent shall be reported in terms of Standard Pyrometric Cones and shall be that cone which most nearly corresponds in time of softening with the test cone. If the test cone softens later than one Standard Pyrometric Cone but earlier than the next Standard Pyrometric Cone and approximately midway between, the P. C. E. shall be reported thus: cone No. 31–32.

(*b*) If the test cone starts bending at an early cone but is not down until a later cone, the fact should be reported.

NOTE.—The temperatures corresponding to the end points of the Standard Pyrometric Cones are frequently of interest. These are shown in the Appendix.

APPENDIX

The temperatures corresponding to the end points of those Standard Pyrometric Cones that are used in connection with refractories are as follows:

Cone	End Point		Cone	End Point	
	Deg. Fahr.	Deg. Cent.		Deg. Fahr.	Deg. Cent.
No. 15	2615	1435	No. 30	3002	1650
No. 16	2669	1465	No. 31	3056	1680
No. 17	2687	1475	No. 32	3092	1700
No. 18	2714	1490	No. 32½	3131	1722 (approx.)
No. 19	2768	1520	No. 33	3173	1745
No. 20	2786	1530	No. 34	3200	1760
No. 23	2876	1580	No. 35	3245	1785
No. 26	2903	1595	No. 36	3290	1810
No. 27	2921	1605	No. 37	3308	1820
No. 28	2939	1615	No. 38	3335	1835
No. 29	2984	1640			

These temperatures (except cone No. 32½), which were determined by Fairchild and Peters[5] for a heating rate of 270 F. (150 C.) per hr. for cones Nos. 15 to 20 and of 180 F. (100 C.) per hr. for cones Nos. 23 to 38, other conditions being the same as specified, apply satisfactorily for all the conditions of this test method, but do not apply to conditions of the commercial burning and use of refractory materials.

Standard Method of

PANEL TEST FOR RESISTANCE TO THERMAL AND STRUCTURAL SPALLING OF REFRACTORY BRICK[1]

A.S.T.M. Designation: C 38 – 42

ADOPTED, 1936; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 38; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) This method of test outlines a general procedure for determining the resistance of refractory brick to the separate and combined effects of structural and thermal spalling. The test is believed to give a sufficient simulation of service conditions to suggest its use as a suitability test for certain classes of service that have been correlated with the test data.

(*b*) Detailed methods of test to be used in conjunction with this procedure in testing specific types of refractories are as follows:

Method of Panel Test for Resistance to Thermal and Structural Spalling of High Heat Duty Fireclay Brick (A.S.T.M. Designation: C 107),[3]

Method of Panel Test for Resistance to Thermal and Structural Spalling of Super Duty Fireclay Brick (A.S.T.M. Designation: C 122)[3], and

Method of Panel Test for Resistance to Thermal and Structural Spalling of Fireclay Plastic Refractories (A.S.T.M. Designation: C 180).[3]

Apparatus

2. The apparatus and equipment[4] shall consist of the following:

(*a*) *Panel Frame.*—A panel framework shall be used which is essentially the same as that shown in Fig. 1.

(*b*) *Preheating Furnace.*—A preheating furnace shall be used, constructed essentially like the design shown in Figs. 2 and 3.

(*c*) *Spalling Furnace.*—A spalling furnace shall be used, constructed in a manner as shown in Figs. 4, 5, and 6.

(*d*) *Temperature Measuring Instruments.*—The temperature of the test panel during the preheating shall be measured by means of an optical pyrometer. The spalling furnace temperature shall be determined by means of a platinum - platinum-rhodium thermocouple.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1936. This method replaced the former water spalling method which was published as tentative from 1921 to 1934, being revised in 1926, 1927, 1931, and 1933, and which was accordingly discontinued in 1934.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] The complete set of drawings necessary for the construction of the panel spalling equipment would require too much space to be included with the procedure, but these are available at a nominal charge from the Refractories Fellowship, Mellon Institute of Industrial Research, Pittsburgh, Pa.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

(*e*) *Air Supply.*—Means shall be provided for delivering air through each cooling unit at a specified rate.

(*f*) *Transfer Facilities.*—A suitable means, such as a track or trolley, shall be provided for transferring the test panels.

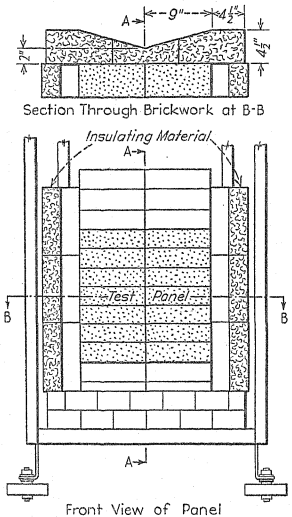

FIG. 1.—Panel Frame and Brickwork.
The brick around the test panel are dummy brick which are used to help maintain uniform conditions within the panel.

Test Specimens

3. Whenever possible, the specimens for the test panel shall consist of 9-in. straight brick. When shapes of other sizes are to be tested, the specimens shall be cut so as to be not more than 3 in. in thickness by not more than 9 in. in length by not more than $4\frac{1}{2}$ in. in width.

Panel Construction

4. The specimens shall be laid up so as to form a test panel not less than 18 in. square, so that a 9 by $2\frac{1}{2}$-in. surface of each specimen will be exposed to the heat treatment. Each specimen shall be labeled with ceramic paint on the face opposite that to be tested, and then weighed to the nearest 0.1 lb. There shall be placed about the test panel a suitable grade of refractory dummy brick, in the manner shown in Fig. 1. All brick in the test panel shall be laid up with refractory kaolin unless otherwise specified. The joints shall be not thicker than $\frac{1}{16}$ in. The test panel, including dummy brick, shall be insulated in accordance with the arrangement and design shown in Fig. 1.

Preheating Test Panels

5. The prepared test panels shall be placed in position on either side of the preheating furnace. When only one lot of brick is to be tested, a dummy panel should be used. The joint between the ends of the panel dummy brick and the preheating furnace shall be sealed with plastic kaolin. During the heating of the panels, the surface of the test specimen opposite that being heated shall be insulated in the specified manner so as to maintain a suitable temperature gradient in the specimen. The furnace shall be so operated that the temperature specified for preheating shall be reached in not less than 5 nor more than 8 hr. and maintained 24 hr. The permissible variation in temperature may be plus 35 F. and minus 45 F. (plus 20 C. and minus 25 C.), but the average of the temperature during the run shall be that specified. After completing the preheating, the test panel shall be left in position for not less than 8 hr. before being removed. As a result of this heat treatment, any tendency toward fusion, vitrification, swelling, or shrinkage will

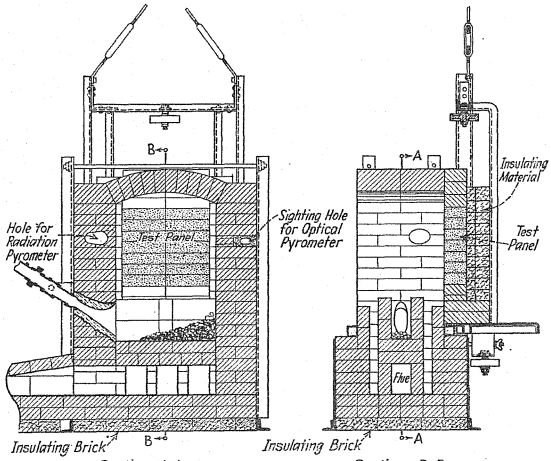

FIG. 2.—Design of Preheating Furnace.
In Section B-B there is shown in position one of the two panels used during the preheating.

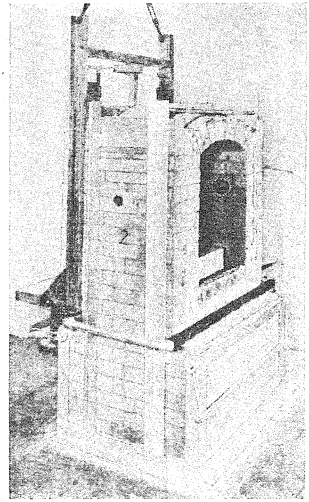

FIG. 3.—Preheating Furnace with Panel in Position on Far Side of Furnace.

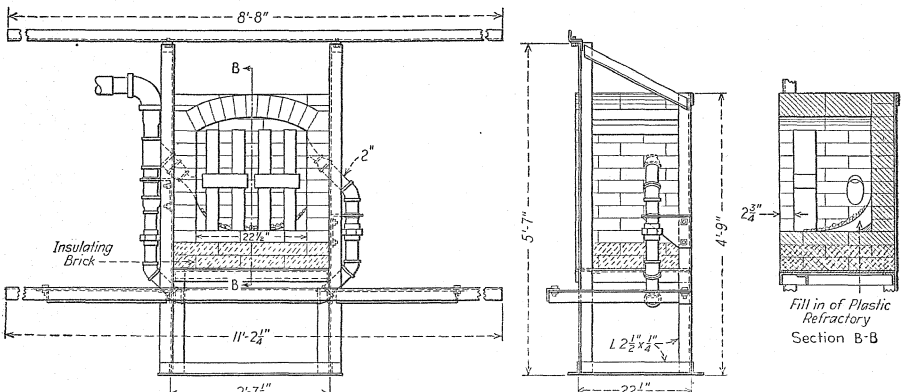

FIG. 4.—Furnace of the Spalling Equipment.
The complete layout is shown in Figs. 5 and 6.

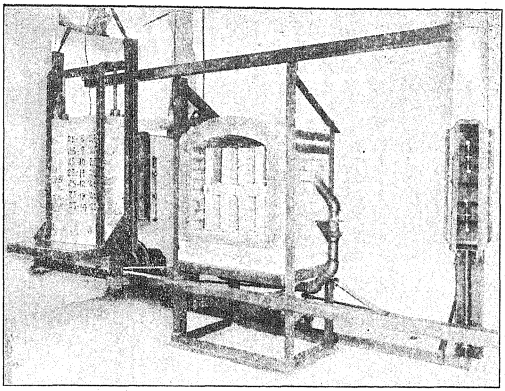

FIG. 5.—Spalling Equipment for Panel Spalling Test.

Front view showing one of the two panels in position. During the test a second panel is placed in front of the furnace opening. The two panels are linked together so that when the one which is now in the position for cooling is moved in front of the furnace, the other panel will be in position in front of the right-hand cooling unit. By this means, each panel is alternately heated and cooled.

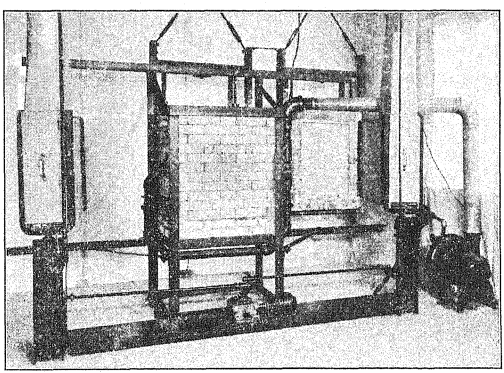

FIG. 6.—Cooling Equipment for Panel Spalling Test.

View from the back of the furnace showing the panels in position. There is shown the nature of the mechanism which causes the air manifolds to operate with a reciprocating motion and the motor blower unit used to operate the furnace.

be evident and any development of structural spalling will be apparent. A record shall be made of the condition of the brick specimens, indicating the extent of the fusion, vitrification, swelling,

Spalling Procedure

6. The test panels shall then be subjected to thermal spalling by heating them within a specified time to a specified temperature and rapidly cooling

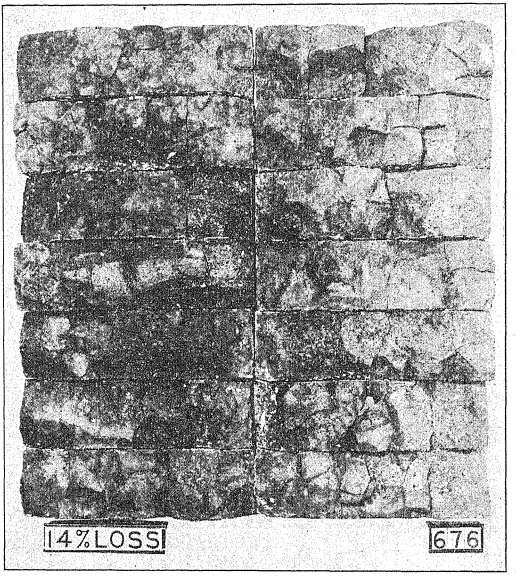

FIG. 7.—Photograph Showing Manner in Which Test Brick Are to Be Arranged for Making Photographic Report.
The brick are in the same corresponding position as laid up in the panel. The percentage loss and photograph number or designation are also shown.

or shrinkage. If shrinkage takes place a record shall be made of its nature, that is, whether or not this occurs as a shrinkage of each brick as a unit, or as the development of cracks on the surface of each brick. The surface of the test panels may be photographed.

by means of a prescribed blast. The panels shall be placed in position in front of the spalling furnace in the manner shown in Figs. 5 and 6. The temperature of the spalling furnace shall be raised within 3 hr. to the specified temperature. During the heating pe-

riod, the panels shall be alternately placed in position in front of the furnace so that each may be heated to about the same temperature. The position of the panels shall be changed at temperatures of 720, 360, and 180 F. (400, 200, and 100 C.) below the final furnace temperature. During this period, the test panels shall not be cooled by means of the cooling blast. After the final temperature of spalling is obtained, the panels shall be held in position for a specified time, and then shifted so as to expose the heated panel for cooling. After each panel has been subjected to the required number of cycles, the furnace shall be allowed to cool, but the cooling procedure for the test panels shall be conducted so that each panel receives two additional cycles without the water mist.

Dismantling Test Panel

7. When the test panel has cooled sufficiently so that the brick can be handled, the panel shall be carefully dismantled. Each of the test specimens shall be cleaned to free it of kaolin and in such a manner as to remove spalls, after which the specimens shall be reweighed to the nearest 0.1 lb., and the loss in weight recorded as percentage of the original weight. When a second heating treatment is given and the 9-in. brick specimens have been numbered from 1 to 7 from top to bottom in the test panel, their order shall be changed so as to assume the positions of 4–3–2–1–7–6–5. In the case of the six 3-in. brick specimens the order shall be changed so as to assume the positions of 3–2–1–6–5–4 for the second heating treatment. The specimens shall also be turned end for end.

Report

8. The report may include a photograph of the test panel after preheating, and shall include comments as to its condition. The average spalling loss for the whole panel shall be given, as well as a photograph of the spalled brick specimens arranged in the manner shown in Fig. 7.

Standard Method of

PANEL TEST FOR RESISTANCE TO THERMAL AND STRUCTURAL SPALLING OF HIGH HEAT DUTY FIRECLAY BRICK[1]

A.S.T.M. Designation: C 107 - 42

ADOPTED, 1936; REVISED, 1940, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 107; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the resistance of fireclay brick used for stationary boilers, malleable iron furnace bungs, and incinerator furnaces to the separate and combined effects of structural and thermal spalling. This method makes use of the general requirements and procedure prescribed in the Method of Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick (A.S.T.M. Designation: C 38) of the American Society for Testing Materials,[3] and supplements that method by giving the detailed requirements of the procedure to be followed in testing refractories for use in stationary boilers, malleable iron furnace bungs, and incinerator furnaces.

Apparatus and Test Specimens

2. The apparatus and test specimens shall be in general as described in the Method of Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick (A.S.T.M. Designation: C 38) of the American Society for Testing Materials.[3]

Procedure

3. The procedure shall be in general as outlined in Method C 38,[3] supplemented by the procedure for preheating and spalling as prescribed in the following Sections 4 and 5.

Preheating Test Panels

4. (*a*) The test brick shall be laid up with kaolin having a pyrometric cone equivalent not below cone No. 34.

(*b*) The test panels and dummy brick shall be insulated with group 26 insulating fire brick weighing 46 ± 2 lb. per cu. ft.

(*c*) The temperature of the panel faces shall be maintained so as to average 2910 F. (1600 C.) by means of a gas-fired furnace for a period of 24 hr.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1936.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

(*d*) The furnace gas pressure during the 24-hr. preheating period shall be within the limits of 0.3 to 0.6 in. of water for gas-fired furnaces.

NOTE.—In furnaces used for the purpose of obtaining control and experimental data where the method is followed in all details except that oil is used as a fuel, it is recommended that the furnace gas pressure be maintained between 0.1 and 0.2 in. of water.

Spalling Procedure

5. (*a*) The panel insulation shall be removed.

(*b*) The gas-fired furnace shall be operated so as to obtain a temperature of 2550 F. (1400 C.) before the panels are cooled by means of the blast.

(*c*) The period for heating shall be 10 min. and for cooling 10 min., making a 20-min. cycle.

(*d*) The cooling shall be accomplished by means of an air-water mist blast, which shall be delivered through a vertical manifold with an opening measuring $3\frac{1}{2}$ by 24 in. as shown in Method C 38.[3] Air shall be delivered through each cooling unit at the rate of 1400 cu. ft. per min. The water used in the four spray units shall be filtered and measured by means of a meter. The spray nozzles shall be regulated so as to deliver water at the rate of $2\frac{1}{2}$ gal. during the first 8 min. of the cycle. No water shall be used during the last 2 min. The cooling units shall be operated with a reciprocating motion so as to pass back and forth across the surface of the entire panel, including the dummy guard brick, 125 times in 10 min.

(*e*) The spalling treatment shall consist of 12 cycles, after which the furnace shall be shut off and the panels given two additional cooling cycles without the water mist.

(*f*) After carefully dismantling the panel, the kaolin shall be scraped off with a trowel, removing such pieces of the brick as separate easily. No attempt shall be made to separate pieces that might be removed by prying or tapping.

Standard Method of

PANEL TEST FOR RESISTANCE TO THERMAL AND STRUCTURAL SPALLING OF SUPER DUTY FIRECLAY BRICK[1]

A.S.T.M. Designation: C 122 - 42

ADOPTED, 1937; REVISED, 1940, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 122; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the resistance of super duty fireclay brick to the separate and combined effects of structural and thermal spalling. This method makes use of the general requirements and procedure prescribed in the Method of Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick (A.S.T.M. Designation: C 38) of the American Society for Testing Materials,[3] and supplements that method by giving the detailed requirements of the procedure to be followed in testing super duty fireclay brick.

Apparatus and Test Specimens

2. The apparatus and test specimens shall be in general as described in the Method of Panel Test for Resistance to Thermal and Structural Spalling of Refractory Brick (A.S.T.M. Designation: C 38) of the American Society for Testing Materials.[3]

Procedure

3. The procedure shall be in general as outlined in Method C 38,[3] supplemented by the procedure for preheating and spalling as prescribed in the following Sections 4 and 5.

Preheating Test Panels

4. (*a*) The test brick shall be laid up with kaolin having a pyrometric cone equivalent not below cone No. 34.

(*b*) The test panels and dummy brick shall be insulated with group 26 insulating fire brick weighing 46 ± 2 lb. per cu. ft.

(*c*) The temperature of the panel faces shall be maintained so as to average 3000 F. (1650 C.) by means of a gas-fired furnace for a period of 24 hr.

(*d*) The furnace gas pressure during the 24-hr. preheating period shall be within the limits of 0.3 to 0.6 in. of water for gas-fired furnaces.

NOTE.—In furnaces used for the purpose of obtaining control and experimental data where the method is followed in all details except that oil is used as a fuel, it is recommended that the furnace gas pressure be maintained between 0.1 and 0.2 in. of water.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1937.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

Spalling Procedure

5. (*a*) The panel insulation shall be removed.

(*b*) The gas-fired furnace shall be operated so as to obtain a temperature of 2550 F. (1400 C.) before the panels are cooled by means of the blast.

(*c*) The period for heating shall be 10 min. and for cooling 10 min., making a 20-min. cycle.

(*d*) The cooling shall be accomplished by means of an air-water mist blast, which shall be delivered through a vertical manifold with an opening measuring 3½ by 24 in. as shown in Method C 38.[3] Air shall be delivered through each cooling unit at the rate of 1400 cu. ft. per min. The water used in the four spray units shall be filtered and measured by means of a meter. The spray nozzles shall be regulated so as to deliver water at the rate of 2½ gal. during the first 8 min. of the cycle. No water shall be used during the last 2 min. The cooling units shall be operated with a reciprocating motion so as to pass back and forth across the surface of the entire panel, including the dummy guard brick, 125 times in 10 min.

(*e*) The spalling treatment shall consist of 12 cycles, after which the furnace shall be shut off and the panels given two additional cooling cycles without the water mist.

(*f*) After carefully dismantling the panel, the kaolin shall be scraped off with a trowel, removing such pieces of the brick as separate easily. No attempt shall be made to separate pieces that might be removed by prying or tapping.

Standard Method of Test for

PERMANENT LINEAR CHANGE AFTER REHEATING OF REFRACTORY BRICK[1]

A.S.T.M. Designation: C 113 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 113; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers a procedure for determining the permanent linear change of certain types of refractory materials when heated under prescribed conditions.

Apparatus

2. The apparatus shall consist of a kiln of the down-draft type and of such design as not to permit the flame to impinge directly from the burner upon the test specimens. The kiln atmosphere during the test shall be kept as oxidizing as is practicable.

Test Specimens

3. (*a*) The test specimens shall consist of three standard 9-in. brick (9 by 4½ by 2½ in.) or three pieces of these dimensions cut out of larger shapes.

(*b*) Each test specimen shall be labeled with ceramic paint and carefully measured for length before and after reheating. The measurements shall be made by the use of a firm joint caliper and a steel rule. The calipering shall be done at the center of each end, and the dimension shall be measured to the nearest 0.02 in.

Location of Test Specimens in Kiln

4. The test specimens shall be placed in the kiln so that each will rest on a 9 by 2½-in. face and only one course high. Each specimen shall be placed upon the 9 by 2½-in. face of a supporting brick which shall be from the same lot as the test specimen or at least of equal refractoriness. There shall be placed between the test specimen and the supporting brick a layer of calcined diaspore, cyanite, or fused alumina ground to pass a No. 20 (840-micron) A.S.T.M. sieve (equivalent to mesh No. 20 of the Tyler standard series). Each specimen shall be placed so as to be not closer than 1½ in. from other test specimens or the furnace wall.

Temperature Measurement

5. (*a*) The temperature within the kiln shall be measured by means of a

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1936. Editorially revised in 1942.

platinum - platinum-rhodium thermocouple and a pyrometer, preferably a recording pyrometer. The hot junction of the couple shall be placed so as to register the temperature of the test specimens. The kiln shall be of uniform temperature over the hearth and shall be checked from time to time by means of cones and shall not show a difference of more than one cone. Above 2640 F. (1450 C.) the thermocouple should be

Test Temperature Schedules

6. The kiln shall be operated so as to conform to the temperature schedule specified for the particular test to be conducted. Heating schedules for various classes of refractories are shown in Table I.

Cooling

7. After completion of the heating period the test specimens shall be allowed

TABLE I.—HEATING SCHEDULE FOR REHEAT TEST OF VARIOUS TYPES OF REFRACTORIES.[a]

Elapsed Time from Start of Heating	Temperature of Test Specimen			
	Schedule A	Schedule B	Schedule C	Schedule D
1 hr.....	between 1290 and 1470 F. (700 and 800 C.)	between 1650 and 1830 F. (900 and 1000 C.)	between 1650 and 1830 F. (900 and 1000 C.)	between 1515 and 1695 F. (825 and 925 C.)
2 hr.....	between 1965 and 2055 F. (1075 and 1125 C.)	between 2325 and 2415 F. (1275 and 1325 C.)	between 2325 and 2415 F. (1275 and 1325 C.)	between 2235 and 2325 F. (1225 and 1275 C.)
3 hr..	2190 ± 20 F. (1200 ± 10 C.) maintained for 5 hr.	2550 ± 20 F. (1400 ± 10 C.) maintained for 5 hr.	between 2640 and 2730 F. (1450 and 1500 C.)	2460 ± 20 F. (1350 ± 10 C.) maintained for 5 hr.
4 hr.....	.....	.....	between 2820 and 2865 F. (1550 and 1575 C.)	.....
5 hr.....	.....	.....	2910 ± 25 F. (1600 ± 15 C.) maintained for 5 hr.	.....

withdrawn and an optical pyrometer shall be used. The sighting shall be directed on one of the test specimens.

(*b*) During the constant temperature period of the test, the temperature as measured by the thermocouple shall not be allowed to vary by more than plus or minus 20 F. (10 C.) and in the case of the optical pyrometer, plus or minus 25 F. (15 C.) Temperature readings shall be made at intervals not greater than 15 min.

to cool in the closed kiln for a period of at least 10 hr.

Calculation

8. The test specimens shall be remeasured after rubbing the ends with an abrasive block to remove small blisters. The percentage linear change based upon the original length shall be calculated and reported as the average value of the three specimens.

[a] Editorially revised in 1942.

Standard Method of

TESTING FIRECLAY REFRACTORIES UNDER LOAD AT HIGH TEMPERATURES[1]

A.S.T.M. Designation: C 16 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 16; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the resistance to deformation of fireclay refractories when subjected to a specified compressive load at a specified temperature for a specified time.

Apparatus

2. (*a*) The apparatus shall consist essentially of a furnace and a loading device. It may be constructed in accordance with Figs. 1, 2, or 3, or their equivalent.[3]

When gas or oil fuel is used, the furnace shall be of such form that the temperature is substantially uniform in all parts of the furnace. Two burners shall be used. These shall be capable of individual control and located to produce a tangential flame that will not impinge on the specimens or on the thermocouple protecting tubes.

(*b*) The temperature shall be measured either with calibrated platinum - platinum-rhodium thermocouples, each encased in a protection tube with the junction not more than 1 in. (25 mm.) from the center of the side or edge of each specimen farthest from the center of the furnace, or with some form of pyrometer that has been calibrated against a thermocouple in the furnace. A recording form of temperature indicator is recommended. If the optical pyrometer is used, observations shall be made by sighting into refractory tubes having closed ends and in the same relative positions to the test specimens as those specified for the thermocouples.

Test Specimen

3. (*a*) The test specimen shall consist of a minimum of two 9 by 4½ by 2½-in. straight refractory brick, or specimens of this size cut from larger shapes, utilizing as far as possible existing plane surfaces.

(*b*) If necessary, the ends of the

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to its present adoption as standard, this method was published as tentative from 1917 to 1920, being revised in 1920. It was adopted in 1920, published as standard from 1920 to 1939, being revised in 1936, but withdrawn and republished as tentative from 1939 to 1941. Editorially revised in 1942.

[3] Blueprints of detailed drawings of the furnaces shown in Figs. 1, 2, and 3 are available at a nominal cost from the American Society for Testing Materials, 260 S. Broad St., Philadelphia 2, Pa.

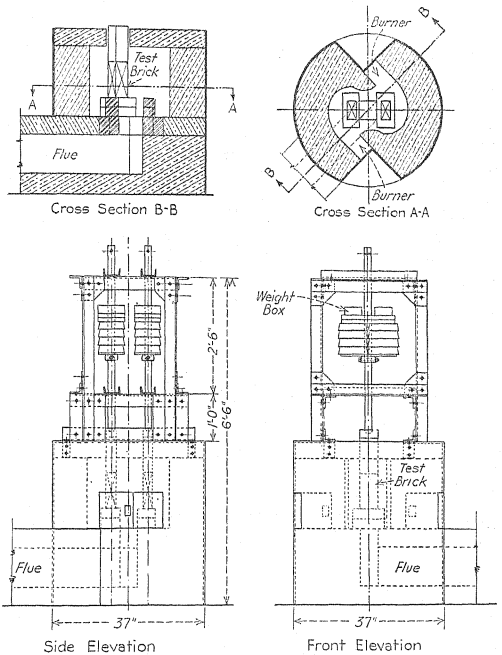

FIG. 1.—Direct-Load-Type Test Furnace.
The furnace is designed with a special contour for good heat distribution. It may be heated with either gas or oil.

(*c*) *Furnace Atmosphere.*—The furnace shall be operated with an oxidizing atmosphere above 1470 F. (800 C.).

(*d*) *Completion of Test.*—At the expiration of the time of heating, the supply of heat shall be stopped and the furnace allowed to cool by radiation to 1830 F. (1000 C.) or lower before the load is removed and the specimens examined. When the test specimens have cooled to room temperature, they shall be remeasured for length in accordance with Section 3(*c*), and the average deformation shall be recorded and reported to the nearest 0.5 per cent of the original length.

NOTE.—It is recommended that a photograph be made of the specimen before and after testing as yielding useful information.

Standard Methods of

TESTING INSULATING FIRE BRICK[1]

COMPRESSIVE STRENGTH, FLEXURAL STRENGTH, AND PERMANENT LINEAR CHANGE AFTER HEATING

A.S.T.M. Designation: C 93 - 42

ADOPTED, 1941; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 93; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover procedures for determining the following properties of insulating fire brick:

Compressive strength,
Flexural strength, and
Permanent linear change as a result of heat treatment.

COMPRESSIVE STRENGTH

Apparatus

2. (*a*) Any universal testing machine[3] may be used.

(*b*) The spherical bearing block shall have a plane bearing surface, the area of which is equal to or greater than the cross-section of the test specimen.

Test Specimens

3. The test specimens shall consist of ten half-brick ($4\frac{1}{2}$ by $4\frac{1}{2}$ by $2\frac{1}{2}$ in.). They shall be placed on the $4\frac{1}{2}$ by $4\frac{1}{2}$-in. surfaces for test. The test surfaces of the specimens shall be approximately parallel planes.

Procedure

4. (*a*) The load shall be applied to the $4\frac{1}{2}$ by $4\frac{1}{2}$-in. surface of the test specimen.

(*b*) The bearing block shall be used on top of the test specimen in vertical testing machines. The bearing block shall be placed on the specimen so that the center of the sphere is in alignment with the vertical axis of the specimen (Fig. 1). The spherical bearing block shall be kept thoroughly lubricated to insure accurate adjustment, which should be made by hand under a small initial load.

(*c*) The testing machine shall be adjusted to apply the load at either of the following rates:

Hydraulic machine....	750 lb. per min. ± 10 per cent
Mechanical machine....	0.05 in. per min. ± 10 per cent

(*d*) During the test, when a mechanically actuated testing machine is used,

---

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these methods were published as tentative from 1933 to 1941, being revised in 1934 and 1939.

[3] The use of a hydraulic testing machine is recommended in preference to the mechanical type.

the beam of the testing machine shall be kept constantly in a floating position.

Calculation

5. The compressive strength in pounds per square inch shall be reported as calculated from the following formula:

$$S = \frac{W}{A}$$

where:

S = compressive strength in pounds per square inch,

W = load in pounds at 3 per cent deformation[4] or at visible failure, whichever is smaller, and

A = average of the gross areas of the top and bottom surfaces of the specimen in square inches.

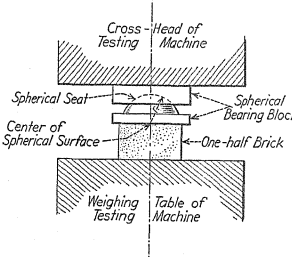

FIG. 1.—Spherical Bearing Block for Compressive Strength Test.

FLEXURAL STRENGTH

Apparatus

6. (*a*) Any universal testing machine[3] may be used.

(*b*) The bearing edges shall be $1\frac{1}{4}$ in. in diameter or rounded to a $\frac{5}{8}$-in. radius. They shall be straight and have full contact with the specimen and shall have a length at least equal to the width of the specimen to be tested. Their bases shall be so curved or rounded as to permit free movement of the working edges. The use of bearing cylinders of the type shown in Fig. 2 is recommended,

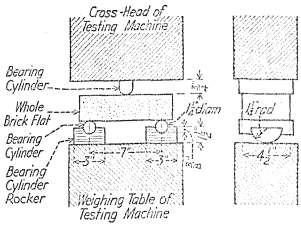

FIG. 2.—Recommended Design of Bearing Cylinders and Rockers for Flexural Strength Test.

although other types may be used, if they provide free movement and at the same time ensure full and even bearing at all times during the test. A satisfactory alternate design is shown in Fig. 3.

Test Specimens

7. At least ten test specimens shall be used and these shall each be a whole 9-in. brick (9 by $4\frac{1}{2}$ by $2\frac{1}{2}$ in.).

Procedure

8. (*a*) The bearing edges shall be placed so as to provide a 7-in. span. A test specimen shall be placed flatwise on the bearing edges and the load applied at mid-span.

(*b*) The testing machine shall be adjusted to apply the load at either of the following rates:

Hydraulic machine.....	200 lb. per min. ± 10 per cent
Mechanical machine....	0.05 in. per min. ± 10 per cent

[4] A dial-type micrometer is generally used for this measurement.

Calculation

9. The flexural strength in pounds per square inch shall be reported as calculated from the following formula:

$$R = \frac{3WL}{2bd^2}$$

where:

R = flexural strength in pounds per square inch,
W = load in pounds at which the specimen failed,
L = distance between the supports in inches,
b = width of the specimen in inches, and
d = depth of the specimen in inches.

(9 by 4½ by 2½ in.). If a specimen of some other size is used, the dimensions shall be reported.

Procedure

13. (*a*) Each test specimen shall be measured along its three major axes through the center. The measurements shall be made to the nearest 0.02 in.

(*b*) The test specimens shall be placed in the furnace preferably on the 9 by 2½-in. edge, resting on a slab of the same composition whose thickness shall be not less than 1 in. The test specimens shall be protected from the direct flame and from localized heating from direct contact with furnace parts.

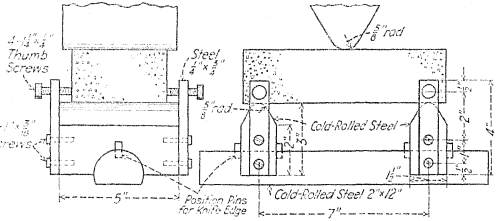

FIG. 3.—Recommended Design of Alternate Apparatus for Flexural Strength Test.

PERMANENT LINEAR CHANGE AFTER HEATING

Purpose

10. The object of this test is to determine the permanent linear change after heating of insulating fire brick when subjected to a definite temperature.

Apparatus

11. Any furnace in which uniform temperatures can be obtained may be used for the test.

Test Specimens

12. Three test specimens shall be used, these preferably being a whole 9-in. brick

(*c*) The maximum temperature to be used shall depend upon the material. This maximum temperature shall be obtained in not less than 3 hr. The maximum temperature shall be held for a period of 24 hr. The specimens shall be left in the furnace until the furnace temperature has fallen at least to 500 F. (260 C.).

Calculation

14. (*a*) *Permanent Linear Change.*—The permanent linear change shall be calculated from measurements taken along the three major axes of the specimens. The change in length, width, and thickness shall be reported separately. The permanent linear change shall be

calculated on the basis of each original dimension.

(*b*) *Permanent Volume Change.*—The permanent volume change shall be calculated from the measurements taken along the three major axes of the specimen in accordance with the following formula:

$$V = \frac{V_o - V_f}{V_o} \times 100$$

where:

V = percentage volume change,
V_o = original volume, and
V_f = final volume.

Standard Methods of Test for

COLD CRUSHING STRENGTH AND MODULUS OF RUPTURE OF REFRACTORY BRICK AND SHAPES[1]

A.S.T.M. Designation: C 133 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 133; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the following tests of refractory brick and shapes: Cold crushing strength and modulus of rupture.

COLD CRUSHING STRENGTH

Apparatus

2. (*a*) *Testing Machine.*—Any form of standard mechanical or hydraulic compression testing machine may be used.

(*b*) *Spherical Bearing Block.*—The spherical bearing block shall have a plane bearing surface, the area of which is equal to or greater than the cross-section of the test specimen.

Test Specimens

3. The test specimens shall be whole standard 9-in. brick (9 by 4½ by 2½ in.) or specimens of equivalent size ground or cut from refractory shapes. In the case of special shapes, only one specimen shall be cut from a single shape and as many of the original surfaces as possible shall be preserved. In preparing specimens from irregular or large refractory shapes, any method involving the use of abrasives, such as high-speed abrasion wheel or rubbing bed, that will produce a specimen with approximately plane and parallel sides without weakening the structure of the specimen may be used.

Preparation of Test Specimen

4. (*a*) The specimen to be used for the cold crushing strength test shall be prepared as follows: The two end surfaces (4½ by 2½ in.) intended to receive the load from the testing machine shall receive a thin coating of shellac and be allowed to dry thoroughly. One of the shellacked bearing surfaces shall then receive a thin coat of a neat mortar of calcined gypsum (plaster of Paris). This mortared face of the specimen shall be pressed on plate glass or other plane, nonporous surface which has been previously oiled or covered with waxed paper, and the bedding material allowed to harden. This procedure shall be

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard these methods were published as tentative from 1937 to 1939.

repeated with the other shellacked surface. Care shall be taken that the opposite faces so coated with bedding material shall be parallel.

(*b*) When the top and bottom surfaces of the specimen are approximately plane and parallel, a cellulose fiber wall board 0.25 in. in thickness and extending 2 in. or more over the edges of the specimen may be substituted for the above method of preparation.

(*c*) The report shall state which type of bedding material is used.

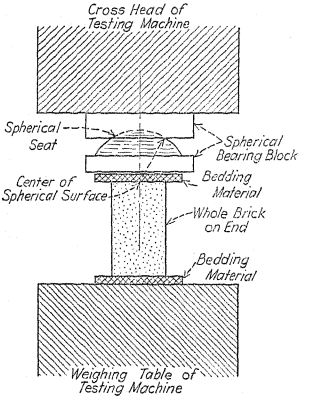

FIG. 1.—Recommended Design for Crushing Test Assembly, Including Bearing Block.

Procedure

5. (*a*) Five specimens shall be tested.

(*b*) The load shall be applied to the 4½ by 2½-in. ends of the test specimen.

(*c*) The bearing block shall be used on top of the test specimen in vertical testing machines. The center of the sphere of the bearing block shall be used in contact with the top bearing surface of the specimen and in the vertical axis of the specimen (Fig. 1). The spherical bearing block shall be kept thoroughly lubricated to insure accurate adjustment, which should be made by hand under a small initial load.

(*d*) The speed of head of the mechanical testing machine during the application of the load shall be not more than 0.5 in. per min. up to a pressure of 500 psi. and not exceeding 0.05 in. per min. for pressures over 500 psi. The rate of application of load, when using a hydraulic testing machine, shall be 20,000 lb. per min.[3]

(*e*) During the test, when a mechanically actuated testing machine is used, the beam of the testing machine shall be kept constantly in a floating position.

Calculation and Report

6. The cold crushing strength in pounds per square inch shall be reported as calculated from the following formula:

$$S = \frac{W}{A}$$

where:

S = cold crushing strength in pounds per square inch,
W = total maximum load, in pounds, indicated by the testing machine, and
A = average of the gross areas of the top and bottom of the specimen, in square inches, of the section of the specimen perpendicular to the line of application of the load

MODULUS OF RUPTURE

Apparatus

7. (*a*) *Testing Machine.*—Any form of standard testing machine may be used.

NOTE.—Portable apparatus properly calibrated may be used.

[3] This paragraph was editorially revised in 1940.

(*b*) *Bearing Edges.*—Bearing edges, $1\frac{1}{4}$ in. in diameter, shall be straight and have full contact with the specimen and shall have a length at least equal to the width of the brick to be tested. Their bases shall be so curved or rounded as to permit free movement of the working edges. The use of bearing cylinders of the type shown in Fig. 2 is recommended, although other types may be used which will provide free movement and at the same time insure full and even bearing at all times during the test. A satisfactory alternate design is shown in Fig. 3.

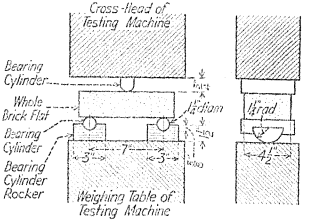

FIG. 2.—Recommended Design of Bearing Cylinders and Rockers for Use in Modulus of Rupture Test.

Test Specimens

8. The test specimens shall conform to the requirements prescribed in Section 3.

Procedure

9. (*a*) Five specimens shall be tested.

(*b*) A test specimen shall be placed flatwise on the bearing cylinders with a span of 7 in. and the load applied at mid-span.

(*c*) The speed of head of the mechanical testing machine during the application of the load shall be not more than 0.05 in. per min. The rate of application of load, when using a hydraulic testing machine, shall be 4000 lb. per min.[3]

Calculation and Report

10. The modulus of rupture in pounds per square inch shall be reported as calculated from the following formula:

$$R = \frac{3Wl}{2bd^2}$$

where:

R = modulus of rupture in pounds per square inch,

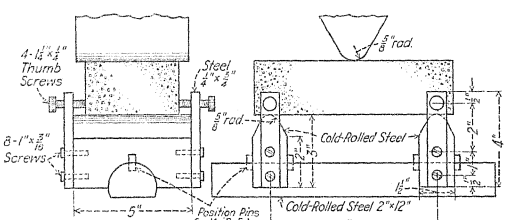

FIG. 3.—Recommended Design of Alternate Apparatus for Modulus of Rupture Test.

W = total load in pounds at which the specimen failed,

l = distance between the supports in inches,

b = width of the specimen in inches, and

d = depth of the specimen in inches.

Standard Methods of Test for
SIZE AND BULK DENSITY OF REFRACTORY BRICK[1]

A.S.T.M. Designation: C 134 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 134; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover procedures for measuring the size and bulk density of rectangular refractory brick.

NOTE.—These methods include a procedure for measuring the size of rectangular refractory shapes.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Rule (12-in.).*—A steel rule 12 in. in length, graduated on one edge in $\frac{1}{8}\frac{1}{0}$ in. and and on the other in $\frac{1}{6}\frac{1}{4}$ in., for use in measuring brick and small shapes. The rule shall have a hook consisting of a right-angled piece on one end to fix the zero point of the scale against one face of the brick. The hook shall be $\frac{1}{4}$ in. in width and shall extend $\frac{1}{4}$ in. beyond the measuring side of the rule as shown in Fig. 1.

(*b*) *Rule (36-in.).*—A stiff steel hooked rule 36 in. in length, graduated in $\frac{1}{3}\frac{1}{2}$, $\frac{1}{6}\frac{1}{4}$, and $\frac{1}{1}\frac{1}{0}$ in. for use in stack measurements and for measuring the larger shapes by use of the hook. The 36-in. rule shall have the same design and the same graduations on the top of the rule as specified for the 12-in. rule, but on the other side and beginning at the opposite end from the hook it shall be graduated in $\frac{1}{3}\frac{1}{2}$ in.

NOTE.—The hooked rules shall be checked periodically to determine whether they have become distorted or worn in use.

(*c*) *Weighing Scale.*—A scale for weighing, having a capacity of 10 lb. or more and a sensitivity under load of at least 0.02 lb. ($\frac{1}{2}$ oz.)

Sampling

3. A sample of 20 brick or shapes shall be selected at random to represent each shipment, and 10 of these brick shall be taken as a primary set of test specimens. The remaining 10 brick shall be retained for retesting, if required.

Preparation of Specimens

4. Any pimples or fins shall be removed from the specimens by lightly rubbing them together.

Measurement of Size

5. (*a*) *Length and Width.*—The length and width of each of the 10 specimens shall be measured across the middle of

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these methods were published as tentative from 1938 to 1941, being revised in 1939.

each of the faces of largest area to the nearest $\frac{1}{8}$ in. or $\frac{1}{64}$ in. when the dimensions are 9 in. or under, and to the nearest $\frac{1}{2}$ or $\frac{1}{32}$ in. when the dimensions are over 9 in. The position of the hooked rule for these measurements is indicated by lines L and W in Fig. 2. The individual measurements of the two opposite faces of each specimen shall be made and recorded.

(*b*) *Thickness.*—The 10 specimens shall first be stacked on a plane surface without regard to the position of the brand marks on the specimens. The stack shall then be measured to the nearest $\frac{1}{32}$

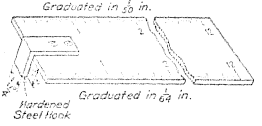

FIG. 1.—Design of 12-in. Hooked Rule.

in. from the plane surface to the top of the stack at the center of each side. The individual measurements of the four sides of the stack shall be recorded.

NOTE.—Brick or shapes over 3 in. in thickness shall be measured for thickness by the procedure described in Paragraph (*a*). The position of the hooked rule for the thickness measurements is indicated by the line T in Fig. 2.

Report

6. The average of the two individual measurements for length and for width of each specimen shall be reported. The thickness shall be reported as the average stack height divided by 10, except for those thickness measurements on brick over 3 in. in thickness obtained by the use of a hooked rule, which shall be reported as the average thickness of the individual specimens.

Retests

7. (*a*) If one specimen in the primary set of 10 specimens fails to conform to the length or width requirements specified, the length and width of the second set of 10 specimens shall be measured in accordance with Section 5 (*a*), and 19 of the 20 specimens must conform to the requirements specified.

(*b*) Failure of the stack thickness to conform to the requirements specified

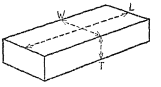

FIG. 2.—Measurements of Refractory Brick.

shall constitute cause for rejection. Thickness measurements obtained on individual specimens (that is, brick or shapes over 3 in. in thickness measured by use of the hooked rule) shall be subject to retest in accordance with Paragraph (*a*).

Bulk Density

8. Each of the specimens shall be weighed to the nearest 0.02 lb. ($\frac{1}{4}$ oz.), the weight recorded, and the average weight of the 10 specimens calculated. The average volume shall be calculated by using the average dimensions obtained in accordance with Section 6. The bulk density shall be calculated as follows:

$$\text{Bulk density, lb. per cu. ft.} = \frac{\text{wt. in lb.}}{\text{vol. in cu. in.}} \times 1728$$

Standard Method of Test for

WARPAGE OF REFRACTORY BRICK AND TILE[1]

A.S.T.M. Designation: C 154 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 154; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the warpage of refractory brick and tile.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Steel Straightedge.*

(*b*) *Measuring Wedge.*—A steel wedge

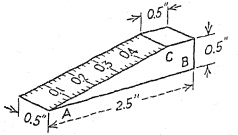

FIG. 1.—Measuring Wedge.

2.5 in. in length by 0.5 in. in width by 0.5 in. in thickness at one end, and tapered, starting at a line 0.5 in. from one end, to zero thickness at the other end. The wedge shall be graduated in 0.02 in. and numbered to show the thickness of the wedge between the base *AB* and the slope *AC*, as illustrated in Fig. 1.

Sampling[3]

3. The sample of brick or tile consisting of 20 pieces shall be taken at random to represent a shipment of a carload or fraction thereof.

Procedure

4. Place the straightedge across a diagonal on the concave side of the tile.

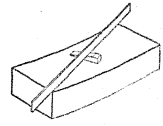

FIG. 2.—Method of Measuring Warpage.

Insert the wedge (Fig. 2) at the point of maximum warpage, and note the reading to the nearest 0.02 in. Repeat on the other diagonal.

Report[4]

5. The warpage shall be taken as the larger of the two measurements of each specimen. The report shall give the warpage values for the individual specimens.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to its present adoption as standard, this method was published as tentative from 1938 to 1939, constituting a portion of the Tentative Methods of Test for Size, Warpage, and Bulk Specific Gravity of Refractory Brick (C 134 – 38 T). This method was reissued in 1940 under the serial designation C 154, and published as tentative from 1940 to 1941.

[3] This section was added editorially in 1943 to correct an omission.

[4] This section was editorially revised in 1943.

Standard Methods of Test for

APPARENT POROSITY, WATER ABSORPTION, APPARENT SPECIFIC GRAVITY, AND BULK DENSITY OF BURNED REFRACTORY PRODUCTS[1]

A.S.T.M. Designation: C 20 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 20; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods of test cover procedures for determining the following properties of burned refractory products:

Apparent porosity,
Water absorption,
Apparent specific gravity, and
Bulk density.

NOTE.—These methods are not applicable to materials attacked by water.

Preparation of Sample

2. (*a*) The sample shall consist of at least five standard 9-in. brick or similar units, from each of which a single test specimen, having a volume of approximately 25 or 26 cu. in. shall be cut or broken. When testing standard 9-in. straight brick, the specimen shall be a quarter-brick obtained by halving the brick along a plane parallel to the 9 by 2½-in. face and along a plane parallel to the 4½ by 2½-in. face. Four of the surfaces of the resultant quarter-brick specimen include part of the original molded faces. These surfaces are half of one end, half of one side and one quarter of each of the two 9 by 4½-in. faces. When testing large shapes, the sample shall consist of several specimens cut or broken from each shape from both the center and outer portions.

(*b*) Each specimen shall be freed of all loosely adhering particles.

(*c*) Visibly defective specimens shall not be used.

Dry Weight, *D*

3. (*a*) The test specimens shall be dried to constant weight by heating to 220 to 230 F. (105 to 110 C.) and the dry weight, *D*, in grams determined to the nearest 0.1 g.

(*b*) The drying procedure may be omitted only when the test specimens

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to their present adoption as standard, these methods were published as tentative from 1918 to 1920. They were adopted in 1920, published as standard from 1920 to 1939, being revised in 1931 and 1933, but withdrawn and republished as tentative from 1939 to 1941. Editorially revised in 1942 and 1943.

are known to be dry, as may be the case with samples taken directly from kilns.

(*c*) The drying of the specimens to constant weight and the determination of their dry weights may be done either before or after the boiling operation (Section 4). Usually the dry weight is determined before boiling; if, however, the specimens are friable or evidence indicates that particles have broken loose during the boiling operation, the specimens shall be dried and weighed after the suspended weight, *S*, and the saturated weight, *W*, have been determined as described in Sections 5 and 6. This second dry weight shall be used in all appropriate calculations.

Boiling

4. (*a*) The test specimens shall be placed in water and boiled for 2 hr. During the boiling period, they shall be kept entirely covered with water, and shall not be in contact with the heated bottom of the container.

(*b*) After the boiling period, the test specimens shall be cooled to room temperature while still completely covered with water. The cooling may be accelerated by running cold water into the container.

Suspended Weight, *S*

5. (*a*) The weight, *S*, of each test specimen after boiling and while suspended in water shall be determined in grams to the nearest 0.1 g.

(*b*) This weighing is usually accomplished by suspending the specimen in a loop or halter of 22-gage copper wire hung from one arm of the balance The balance shall be previously counterbalanced with the wire in place and immersed in water to the same depth as is used when the refractory specimens are in place.

Saturated Weight, *W*

6. After determining the suspended weight, each specimen shall be blotted lightly with a moistened smooth linen or cotton cloth to remove all drops of water from the surface and the saturated weight, *W*, determined in grams by weighing in air to the nearest 0.1 g. The blotting operation shall be performed by rolling the specimen lightly on the wet cloth, which has previously been saturated with water and then pressed only enough to remove such water as will drip from the cloth. Excessive blotting will introduce error by withdrawing water from the pores of the specimen.

Exterior Volume, *V*

7. The volume, *V*, in cubic centimeters of the test specimens may be obtained by subtracting the suspended weight from the saturated weight, both in grams, as follows:

$$V = W - S$$

NOTE.—This assumes that 1 cu. cm. of water weighs 1 g. This is true within about three parts in 1000 for water at room temperature.

Volumes of Open Pores and Impervious Portions

8. The volume of open pores and the volume of the impervious portions of the specimen may be calculated as follows:

Vol. of open pores in cu. cm. $= W - D$
Vol. of impervious portion in cu. cm. $= D - S$

Apparent Porosity, *P*

9. The apparent porosity expresses as a percentage the relationship of the volume of the open pores of the specimen to its exterior volume and shall be calculated as follows:

$$P = \frac{W - D}{V} \times 100$$

Water Absorption, *A*

10. The water absorption, *A*, expresses as a percentage the relationship of the weight of water absorbed to the weight of the dry specimen and shall be calculated as follows:

$$A = \frac{W - D}{D} \times 100$$

Apparent Specific Gravity, *T*

11. The apparent specific gravity, *T*, of that portion of the test specimen which is impervious to boiling water shall be calculated as follows:

$$T = \frac{D}{D - S}$$

Bulk Density, *B*

12. (*a*) The bulk density, *B*, in grams per cubic centimeter of a specimen is the quotient of its dry weight divided by the exterior volume, including pores and shall be calculated as follows:

$$B = \frac{D}{V}$$

(*b*) This method of determining bulk density is useful for checking bulk density values obtained by the direct measurement method[3] (Note). While it is more accurate than the direct measurement method, and generally gives higher values (by about 0.02 to 0.04), the direct measurement method is better suited for plant and field testing, since it is a less involved technique. The present method is preferable for specimens which are branded deeply or irregular in contour.

NOTE.[4]—The values for bulk density determined according to Section 12 will be expressed in metric units, for example, grams per cubic centimeter. The bulk density, however, determined by the direct measurement method will be expressed in English units. The conversion from metric to English units may be calculated as follows:

Bulk density in g. per cu. cm. × 62.43 = Bulk density in lb. per cu. ft.

Report

13. (*a*) For each property, the average of the values obtained with at least five specimens, and preferably also the individual values, shall be reported.[5]

(*b*) Apparent porosity and water absorption results shall be reported to one decimal place, and apparent specific gravity and bulk density results to two decimal places.

NOTE.—When values are reported for water absorption but not for porosity, it is suggested that the report shall also give the results for bulk density. This makes it possible to calculate the corresponding apparent porosity values as follows:

$$P = A \times B$$

[3] Methods of Test for Size and Bulk Density of Refractory Brick (A.S.T.M. Designation: C 134), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] This note was added editorially in 1944.

[5] When there are pronounced differences among the individual values, another sample of five specimens shall be tested. These shall consist of the quarter-brick diagonally opposite from the original specimens. The average of all ten determinations shall be reported.

Standard Method of Test for

TRUE SPECIFIC GRAVITY OF BURNED REFRACTORY MATERIALS[1]

A.S.T.M. Designation: C 135 - 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 135; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers a procedure for the determination of true specific gravity of refractory materials under prescribed conditions.

NOTE.—This method is not applicable to materials attacked by water.

Apparatus

2. The apparatus shall consist of the following: Analytical balance and weights, 50-ml. pycnometer bottle with capillary tube stopper, thermometer, drying oven, weighing bottle, desiccator, a suitable apparatus to produce a vacuum of 0.5 to 1.0 in. mercury pressure, and distilled water at room temperature.

Test Specimens

3. (*a*) The test specimen shall consist of two walnut-size pieces cut from different positions in the sample in such a way as to exclude all skin surfaces. If an average specific gravity is desired, specimens from at least five samples shall be tested.

(*b*) The specimen shall be crushed, if necessary, between hardened steel surfaces and then ground in an agate mortar, either by hand or by a mechanical sample grinder[3] so constructed as to prevent the introduction of any impurity. The specimen shall then be reduced to 50-g. by quartering in the standard manner. Any magnetic material introduced by crushing or grinding shall be removed by means of a magnet. The entire 50-g. sample shall be ground in an agate mortar so that it will pass a No. 100 (149-micron) A.S.T.M. sieve[4] (equivalent to mesh No. 100 of the Tyler standard series). Care shall be taken at all stages of the grinding and quartering not to exclude any portions which are difficult to grind, that is, all selective specimen preparation shall be avoided.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, this method was published as tentative from 1938 to 1940. Editorially revised in 1942.

[3] The McKenna, Carling, Fisher, or similar type sample grinders are satisfactory for this purpose.

[4] Detailed requirements for this sieve are given in the Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

4. (*a*) The 50-g. sample shall be dried to constant weight at 220 to 230 F. (105 to 110 C.) and placed in a glass-stoppered weighing bottle. Duplicate tests shall be made on material from the 50-g. sample. All weights shall be recorded to the nearest 0.0001 g.

(*b*) The pycnometer and stopper shall be dried at 220 to 230 F. (105 to 110 C.) cooled in a desiccator, weighed on an analytical balance, and the weight recorded as weight p. The pycnometer shall then be filled with distilled water at room temperature, t, and again weighed with the stopper in place, recording the weight as W_1. The pycnometer shall then be emptied and again dried.

(*c*) Approximately 8 to 12 g. of the sample shall be placed in the dry pycnometer; the pycnometer, stopper, and sample shall be weighed, and the weight recorded as weight W. The bottle shall next be filled to approximately one-half its capacity with distilled water at room temperature t. The sample and water shall be very thoroughly mixed by stirring with a glass rod and evacuated (Note) at 0.5 to 1.0 in. mercury pressure to remove entrapped air.

NOTE.—A suitable method of evacuation is described in Section 4 (*e*) of the Methods of Test for Specific Gravity of Pigments (A.S.T.M. Designation: D 153) of the American Society for Testing Materials.[5]

(*d*) After evacuation, the bottle shall be filled with distilled water at room temperature t, and the excess water on the tip of the capillary removed by filter paper. The pycnometer and contents shall then be weighed and the weight recorded as weight W_2.

[5] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Calculation

5. (*a*) The true specific gravity shall be calculated in accordance with the following formula:

$$\text{Sp. gr., } t/t = \frac{W - p}{(W - p) - (W_2 - W_1)}$$

where:

t = temperature of the material and the water,
p = weight of the stoppered pycnometer,
W = weight of the stoppered pycnometer and sample,
W_1 = weight of the stoppered pycnometer filled with water, and
W_2 = weight of the stoppered pycnometer, sample, and water.

(*b*) The true density of the sample may be determined without additional measurement in accordance with the following formula:

$$\text{True density} = \text{sp. gr.} \times (d_w - d_a)$$

where:

d_w = density of water at the temperature at which the test was made, and
d_a = density of air at the temperature at which the test was made.[6]

Reproducibility of Results

6. Both determinations shall be reported to the nearest 0.001, and they shall check to within 0.005, or additional determinations shall be made.

[6] Values of $(d_w - d_a)$ for temperature from 15 to 30 C. are given in Table 35, Standard Density and Volumetric Tables, National Bureau of Standards, *Circular No. 19*, p. 52.

Standard Definitions of

TERMS RELATING TO REFRACTORIES[1]

A.S.T.M. Designation: C 71 - 42

ADOPTED, 1928; REVISED, 1931, 1935, 1936, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 71; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

MATERIALS

Bond Fire Clay.—See Plastic or Bond Fire Clay.

Diaspore Clay.—A rock consisting essentially of diaspore bonded by fire clay.

Fire Clay.—A sedimentary clay[3] of low flux content.

NOTE.—It is usually associated with coal measures.

Flint Fire Clay.—A hard or flint-like fire clay occurring as an unstratified massive rock, practically devoid of natural plasticity and showing a conchoidal fracture.

Grog Fireclay Mortar.—Raw fire clay mixed with calcined fire clay, or with broken fireclay brick, or both, all ground to suitable fineness.

Ground Fire Clay.—Fire clay or a mixture of fire clays that have been subjected to no treatment other than grinding or weathering, or both.

High-Temperature Bonding Mortar.—A mixture of refractory materials (such as fire clay, quartzite, chrome ore, magnesite, diaspore, or sillimanite minerals) either raw or calcined, to which other materials, not classified as refractories, have been added for the purpose of increasing the plasticity, giving air-setting properties, or lowering the temperature at which the bond develops.

Nodular Fire Clay.—A rock containing aluminous or ferruginous nodules, or both, bonded by fire clay.

NOTE.—In some districts such clays are called "burley" or "burley flint" clay.

Plastic or Bond Fire Clay.—A fire clay of sufficient natural plasticity to bond nonplastic materials.

Silica Fire Clay.—A refractory mortar consisting of a finely ground mixture of quartzite, silica brick, and fire clay of various proportions.

NOTE.—Sometimes called silica cement by the trade.

PROPERTIES

Abrasion of Refractories.—Wearing away of refractory surfaces by the scouring action of moving solids.

Burning (Firing) of Refractories.—The final heat treatment to which refractory brick and shapes are subjected in the

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-8 on Refractories.

[2] Prior to adoption as standard, these definitions were published as tentative from 1927 to 1928, being revised in 1928.

[3] The definition for the term "fire clay" is based upon the following definition for the term "clay:"

Clay.—An earthy or stony mineral aggregate consisting essentially of hydrous silicates of alumina, plastic when sufficiently pulverized and wetted, rigid when dry, and vitreous when fired at a sufficiently high temperature.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

process of manufacture for the purpose of developing bond and other necessary physical and chemical properties.

Corrosion of Refractories.—Destruction of refractory surfaces by the chemical action of external agencies.

Erosion of Refractories.—Wearing away of refractory surfaces by the washing action of moving liquids.

Pyrometric Cone Equivalent (*P.C.E.*).—The number of that Standard Pyrometric Cone whose tip would touch the supporting plaque simultaneously with a cone of the refractory material being investigated when tested in accordance with the Standard Method of Test for Pyrometric Cone Equivalent (P.C.E.) of Refractory Materials (A.S.T.M. Designation: C 24) of the American Society for Testing Materials.

NOTE.—The terms "fusion point," "softening point," "deformation point," and "melting point" have heretofore been loosely used for "pyrometric cone equivalent."

Slagging of Refractories.—Destructive chemical reaction between refractories and external agencies at high temperatures, resulting in the formation of a liquid.

Spalling of Refractories.—The breaking or crushing of a refractory unit due to thermal, mechanical, or structural causes, presenting newly exposed surfaces of the residual mass.

NOTE.—The causes of spalling may be classified under three main headings, as follows:

Thermal:

(*a*) *Factors Related to Service.*—Rapidity and range of thermal fluctuation; contamination by slags and fluxes; tightness of joints; previous vitrification.

(*b*) *Factors Related to Refractories.*—Degree and uniformity of reversible thermal expansion; heat transfer; elasticity; plastic flow.

Mechanical:

(*a*) *Factors Related to Service.*—Rapid heating of wet brick; abuse in removing clinker and slag; unequal and excessive stresses; pinching; no provision for expansion; thin joints.

(*b*) *Factors Related to Refractories.*—Mechanical strength; toughness; accuracy of shape.

Structural:

(*a*) *Factors Related to Service.*—Slags and fluxes; character of the material in joints; insulation of refractories.

(*b*) *Factors Related to Refractories.*—Vitrification; shrinkage; nature of bond; structure; degree of burning.

Standard Methods of

CHEMICAL ANALYSIS OF GLASS SAND[1]

A.S.T.M. Designation: C 146 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 146; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods for the chemical analysis of glass sand cover procedures for use in referee analysis. While primarily adapted for the analysis of glass sand containing not less than 98 per cent silica, these methods are not intended to preclude the use of any other method that yields results within permissible variations. In any case, the analyst should check the procedure and technique that is employed by means of a National Bureau of Standards' standard sample having a composition comparable with that of the material under test. A list of these standard samples is given in the Bureau's Supplement to *Circular 398*.

Special Solutions Required

2. (*a*) *Purity of Reagents.*—All reagents must be free from such amounts of impurities as would endanger the test in question. For referee analysis, reagents conforming to the specifications of the Committee on Analytical Reagents of the American Chemical Society are recommended.

(*b*) *Correction for Impurities in Reagents.*—Blank determinations on all reagents employed must be carried through each step of the procedure and the final result corrected as may be indicated.

(*c*) *Concentration of Acids.*—Throughout these methods the use of concentrated acids is intended, unless otherwise specified. For example, hydrochloric acid, or HCl, refers to the concentrated acid (sp. gr. 1.19) as furnished by the manufacturer. Diluted acids will be designated as in the following example: "diluted HCl (2:98)" will mean two volumes of the concentrated acid of sp. gr. 1.19, diluted with 98 volumes of distilled water.

(*d*) *Water.*—The term "water" as used in these methods refers only to distilled water.

Preparation of Sample

3. (*a*) The sample received for chemical analysis shall be passed through an 840-micron (No. 20) sieve.[3] Any por-

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, these methods were published as tentative from 1939 to 1943.

[3] Detailed requirements for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

tion of the sample that is retained on the sieve shall be crushed, without contamination, until it will pass through the sieve. The screened sample shall be thoroughly mixed and, if necessary, reduced in size by quartering. Not less than 1 lb. of the prepared sample shall be retained for use in the chemical analysis.

(*b*) If the well-mixed screened sample appears to be nonuniform, the sample for analysis shall be taken by spreading the well-mixed sample on a clean surface, flattening to a depth of approximately 0.5 in., and removing small portions at ten or more representative positions.

Loss on Ignition

4. Transfer 1.0000 g. of the sample, dried at 105 to 110 C., to a clean 25-ml. platinum crucible weighed with cover. Cautiously heat the crucible with contents, at first partially covered, and then at approximately 1000 C. covered. Cool in a desiccator, and weigh. Repeat the heating until constant weight is obtained. The loss in weight multiplied by 100 represents the percentage loss on ignition.

Silicon Dioxide

5. Transfer 0.5000 to 1.0000 g. of the sample, dried at 105 to 110 C., to a clean 25-ml. platinum crucible, add about four times as much anhydrous Na_2CO_3 as the weight of the sample taken, and mix thoroughly by stirring with a platinum rod or wire. Cover the crucible and fuse. When cool, transfer the crucible and melt to a large platinum dish, add water, cover, and digest. As soon as the melt has become detached, remove and thoroughly wash the crucible and cover. Acidify the water extract with diluted HCl (1:2), avoiding loss by effervescence. Evaporate to dryness on a steam or water bath. Cool, add 10 ml. of HCl, digest for 5 to 10 min., and dilute with 200 ml. of hot water. Digest until soluble salts are dissolved. Immediately filter through a S. & S. No. 589 black ribbon, or equivalent, paper; wash the SiO_2 and paper with small portions of hot diluted HCl (1:19) and finally with hot water. Transfer the paper and precipitate to a platinum crucible, weighed with cover, and reserve. Evaporate the filtrate to dryness, cover, and heat the dish and contents at 115 to 120 C. for 1 hr. Cool, dissolve the residue in HCl and water, filter, and wash as before to recover the SiO_2 that escaped the first dehydration. Reserve the filtrate if a further recovery of SiO_2 is contemplated. Transfer the paper and precipitate to the platinum crucible, moisten with a few drops of diluted H_2SO_4 (1:4), and ignite cautiously until the paper is charred. Partially cover the crucible, slowly increase the heat until the carbon has been burned, and then cover the crucible and ignite at approximately 1200 C. for 30 min. In all of the heating, great care must be taken to avoid loss of the powdery SiO_2 through drafts. Cool over a good desiccant and weigh. Repeat the ignition until constant weight is obtained. Moisten the contents of the crucible with 5 ml. of water, add 2 drops of diluted H_2SO_4 (1:1) and add (cautiously) 15 ml. of HF, evaporate to dryness, fume off the excess of H_2SO_4, and ignite at about 1000 C. Cool and weigh. If a 0.5-g. sample was taken, the percentage of SiO_2 is obtained by multiplying by 200 the difference between the original weight of the covered crucible and its contents and the final weight.[4]

[4] Any SiO_2 escaping the double dehydration may be recovered by adding approximately 0.05 g. of ferric iron as chloride or sulfate to the reserved filtrate, precipitating with NH_4OH, filtering, washing to remove sodium salts, drying, igniting at about 1100 C., cooling, and weighing in the customary manner. The residue thus obtained is treated with 5 ml. of HF and 10 drops of diluted H_2SO_4 (1:1), evaporated to dryness, ignited at about 1100 C., and weighed. The SiO_2 recovered, as indicated by the loss in weight, is added to that previously found. The recovery may amount to as much as 1 mg., which represents 0.1 and 0.2 per cent of SiO_2, respectively, for 1 and 0.5-g. samples.

Ferric Oxide

NOTE.—The following procedure is satisfactory for determining iron up to a total of 10 mg. of Fe_2O_3. For larger quantities the size of the sample should be so reduced that the 10 mg. is not exceeded. This may be accomplished by using a smaller sample of the sand, or preferably by taking an appropriate aliquot portion of the solution obtained after decomposition of the 10-g. sample.

6. (*a*) *Special Solutions Required: Potassium Dichromate (0.005 N).*—Recrystallize, three times, the purest grade of $K_2Cr_2O_7$ obtainable. Dry the crystals at 150 C., grind to a fine powder, and dry at 200 C. until constant weight is attained. Dissolve 2.4516 g. of the recrystallized salt in water and dilute to exactly 10 liters. One milliliter of exactly 0.005 *N* $K_2Cr_2O_7$ represents 0.000399 g. of Fe_2O_3.

Stannous Chloride Solution.—Dissolve 150 g. of $SnCl_2 \cdot 2H_2O$ in 100 ml. of HCl and dilute to 1000 ml. with water.

(*b*) *Procedure.*—Transfer 10 g. of the dried sand to a 150 to 200-ml. platinum dish. Moisten the sample with water, and add 5 ml. of diluted H_2SO_4 (1:1).[5] Add cautiously 100 ml. of HF, mix thoroughly by stirring with a platinum rod or spatula, and evaporate to 25 ml. on a steam or sand bath. Add 50 ml. of HF and evaporate to fumes of H_2SO_4. To the gently fuming solution add cautiously, drop by drop, a few drops of HNO_3 to destroy organic matter. Cool, rinse the walls of the dish with water, and again heat to strong fumes of H_2SO_4 in order to expel all HNO_3. Cool the dish and contents, add 100 ml. of water, heat to boiling, filter, and wash the residue and paper with hot water. Reserve the filtrate. Ignite the paper and insoluble matter, fuse with a small amount of Na_2CO_3, and dissolve the melt in diluted H_2SO_4 (1:5). Filter, wash the residue and paper, and combine the filtrate with that previously reserved. Again ignite the paper and insoluble matter. Fuse with a minimum quantity of potassium pyrosulfate ($K_2S_2O_7$), dissolve the melt in diluted H_2SO_4 (1:5) and combine with the reserved filtrates. Dilute or concentrate the combined filtrates so that the volume is approximately 200 ml., thoroughly saturate with H_2S, and digest, preferably overnight. Filter into a 500-ml. Erlenmeyer flask and wash the precipitate and paper with diluted H_2SO_4 (1:99) saturated with H_2S. Boil the filtrate to expel H_2S and reduce the volume to 100 ml. Oxidize any reducing substances that may be present by adding 0.1 *N* $KMnO_4$ until a permanent pink coloration is produced. Add 100 ml. of HCl, heat to boiling, and reduce the iron with the minimum amount of a solution of $SnCl_2$. Titrate electrometrically with standard 0.005 *N* $K_2Cr_2O_7$, using a Roberts electrometric titration apparatus[6] or equivalent to determine the potential. The volume of standard $K_2Cr_2O_7$ necessary to effect oxidation of the ferrous iron is the volume required in passing from the first point of inflection as shown by the potentiometer reading, which indicates the oxidation of residual $SnCl_2$ and initial oxidation of the ferrous iron, to the second point of inflection, which indicates the complete transformation of the iron to the ferric condition. The points of inflection are best determined by means of a graph in which the volumes of $K_2Cr_2O_7$ used are plotted against the resulting electromotive force.

[5] The quantity of H_2SO_4 specified here will be sufficient for sands containing as much as 0.5 per cent total bases (oxides of Fe, Al, Ti, Zr, Ca, Mg, Na, K, etc.). For larger amounts of the bases, proportionately larger quantities of H_2SO_4, up to 20 ml. for 10 per cent Al_2O_3, must be used.

[6] J. C. Hostetter and H. S. Roberts, "Electrometric Titrations, with Special Reference to the Determination of Ferrous and Ferric Iron," *Journal*, Am. Chemical Soc., Vol. 41, p. 1337 (1920); "Electrometric Determination of Iron," *Journal*, Am. Ceramic Soc., Vol. 10, April, 1927 (p. 100 of the *Bulletin*).

Solution for Determination of Al_2O_3, TiO_2, ZrO_2, CaO, and MgO (P_2O_5, V_2O_5)

7. Transfer 25.00 g. of the sand, dried at 105 to 110 C., to a 250 to 300-ml. platinum dish. Thoroughly moisten the sample with 20 ml. of diluted H_2SO_4 (1:1) and add slowly, while stirring constantly with a platinum rod or spatula, 200 ml. of HF. Evaporate to fumes of H_2SO_4 and add a few drops of HNO_3 to the hot solution to destroy organic matter. Repeat the hydrofluoric acid treatment, using 50 ml. of HF. Cool the dish and contents, rinse the walls of the dish with water, and repeat the evaporation to fumes of H_2SO_4. When cool, add 150 ml. of water and heat until soluble salts have dissolved. Filter, wash the residue and paper with hot water, and reserve the filtrate. Ignite the insoluble residue, fuse with a small amount of Na_2CO_3, and dissolve the melt in diluted H_2SO_4 (1:5). Filter, wash the residue and paper, and combine the filtrate with that previously reserved. Ignite the filter and insoluble residue. Fuse with a minimum quantity of potassium pyrosulfate ($K_2S_2O_7$), dissolve the melt in diluted H_2SO_4 (1:5), and combine with the reserved filtrates. Dilute to 250 ml. and saturate the solution with H_2S. Digest, preferably overnight, filter, wash with diluted H_2SO_4 (1:99) saturated with H_2S, and discard the sulfide precipitate. Boil the filtrate to expel H_2S, oxidize with bromine water, boil off the excess of bromine, and precipitate with NH_4OH, using methyl red as the indicator. Filter, and wash the paper and precipitate thoroughly with a hot neutral solution of NH_4NO_3 (2 per cent). Acidify, and reserve the filtrate for the determination of calcium and magnesium (see Sections 12 to 14). Transfer the paper and precipitate to a 400-ml. beaker and add 20 ml. of HNO_3 and 10 ml. of H_2SO_4. Cover, heat cautiously until the solution begins to blacken, and then add HNO_3 drop by drop, allowing each drop to flow down the beaker wall, until all carbonaceous matter has been destroyed. Heat to strong fumes of H_2SO_4, cool, rinse the cover glass and beaker walls, and again heat to fumes of H_2SO_4. Cool, add 150 ml. of water, and heat to dissolve any anhydrous sulfates. Cool the solution, transfer to a 200-ml. volumetric flask, and dilute to the mark. Mix thoroughly, and divide the solution into two 100-ml. aliquot portions.

Determination of Al_2O_3, Fe_2O_3, TiO_2, and ZrO_2 (P_2O_5, V_2O_5)

8. Dilute one of the 100-ml. aliquot portions (Section 7) to 250 ml., heat to boiling, and precipitate with NH_4OH, using methyl red as the indicator. Filter, and wash paper and precipitate thoroughly with a hot, neutral solution of NH_4NO_3 (2 per cent). Ignite the paper and precipitate in a platinum crucible weighed with cover. Moisten the ignited residue with water, add 5 to 10 drops of diluted H_2SO_4 (1:1) and 5 ml. of HF. Evaporate to expel the excess of acids, and gradually increase the temperature until all H_2SO_4 has been expelled and the sulfates decomposed. Cover the crucible and ignite at approximately 1100 C. Cool over a good desiccant, and weigh. Repeat the ignition until constant weight is obtained. The weight of the oxides multiplied by 8 represents the combined percentages of Al_2O_3, Fe_2O_3, TiO_2, and ZrO_2 (P_2O_5, V_2O_5).

Determination of Fe_2O_3, TiO_2, and ZrO_2 (V_2O_5)

9. Dilute the other 100-ml. aliquot portion (Section 7) to 200 ml., add 15 ml. of H_2SO_4, and cool the solution to 10 C. Add slowly, while stirring con-

stantly, a cold solution of cupferron (6 per cent) until no further precipitation occurs. Stir in a little macerated paper, allow the precipitate to settle, filter, and wash the paper and precipitate thoroughly with cold diluted H_2SO_4 (1:9) containing 1.5 g. of cupferron per liter. Drain the paper and precipitate, and transfer to a platinum crucible weighed with cover. Dry the precipitate cautiously and ignite slowly until all carbonaceous matter is destroyed. Cool the crucible, and treat with H_2SO_4 and HF to remove any SiO_2. Evaporate to dryness and then ignite at approximately 1100 C. Cool over a good desiccant, and weigh. Repeat the ignition until constant weight is obtained. The weight of the oxides multiplied by 8 represents the combined percentages of Fe_2O_3, TiO_2, and ZrO_2 (V_2O_5).

Determination of Al_2O_3 (P_2O_5)

10. The percentage of oxides obtained from the ammonium hydroxide precipitation of the first aliquot portion minus the percentage of oxides obtained from the cupferron precipitation of the second aliquot portion represents the percentage of Al_2O_3 (P_2O_5).

Determination of TiO_2 and ZrO_2

11. The percentage of oxides obtained from the cupferron precipitation, minus the percentage of Fe_2O_3 as determined on the separate sample, represents the combined percentage of TiO_2 and ZrO_2 (V_2O_5). If desired, TiO_2 and ZrO_2 may be determined by fusing the cupferron precipitate with $K_2S_2O_7$, taking up the melt in diluted H_2SO_4 (1:9), and first determining titanium colorimetrically with H_2O_2 and then determining zirconium by precipitation as phosphate. If V_2O_5 is present, it imparts a reddish-brown color in the titanium test that is not dissipated by a drop or two of HF.

Determination of CaO

12. Evaporate to 100 ml. the reserved filtrate obtained in the NH_4OH precipitation in Section 7, and add two drops of methyl red (0.02 per cent) and 1 g. of oxalic acid. Heat the solution to boiling, and slowly add NH_4OH until the solution is alkaline. Digest, cool, filter on a small S. & S. No. 589 blue band, or equivalent, paper, and wash the precipitate and paper with a cool, neutral solution of ammonium oxalate (0.1 per cent). Acidify, and reserve the filtrate and washings. Transfer the precipitate and paper to a platinum crucible (weighed with cover), and ignite. Moisten the oxide with a few drops of water, add 10 drops of diluted H_2SO_4 (1:9), and evaporate to dryness. Heat the crucible and contents to dull redness, cool, and weigh. Repeat the ignition until constant weight is obtained. The weight of the $CaSO_4$ multiplied by 1.6476 represents the percentage of CaO.

Determination of MgO

13. Evaporate to 100 ml. the filtrate from the ammonium oxalate precipitation (Section 12). Cool the solution, and add 1 g. of $(NH_4)_2HPO_4$. Stir the solution vigorously, slowly add NH_4OH until the solution is alkaline, and then add 10 ml. of NH_4OH. Allow the solution to stand overnight. Filter, and wash with diluted NH_4OH (5:95). Dry the precipitate and paper in a platinum crucible (weighed with cover), char the paper slowly, and burn off the carbon by gradually increasing the temperature. Cover the crucible, and ignite at 1000 to 1100 C. for 30 min. Cool in a desiccator, and weigh. Repeat the ignition to constant weight. The weight of the $Mg_2P_2O_7$ multiplied by 1.4484 represents the percentage of MgO.

Determination of CaO and MgO (Alternate)

14. If desired, the calcium and magnesium may be precipitated in the evaporated filtrate (Section 12) as follows: Add from 1 to 3 g. of $(NH_4)_2HPO_4$ dissolved in a few milliliters of water, and render the solution ammoniacal. Stir thoroughly to induce precipitation, add 10 ml. of NH_4OH, and allow to stand for 4 to 6 hr. Filter, and wash the precipitated phosphates with cool, diluted NH_4OH (5:95). Ignite the precipitate in a platinum crucible (weighed with cover), cool, and weigh as $Ca_3(PO_4)_2$ plus $Mg_2P_2O_7$. Transfer the weighed residue to a small beaker and dissolve in a little diluted H_2SO_4 (1:9), avoiding more than a 0.5 ml. excess. Add 25 ml. of 75 per cent ethyl alcohol and allow the solution to stand several hours, or overnight if the amount of calcium is very small. Filter, and wash the precipitate with 75 per cent ethyl alcohol. Dissolve the dry precipitate in a very little diluted HCl (1:9) and precipitate as oxalate in as small a volume of solution as possible. Filter, wash, ignite, and weigh the calcium as CaO. The magnesium is determined, by difference, by subtracting the weight of the $Ca_3(PO_4)_2$, as calculated from the weight of the CaO found, from the weight of the combined phosphates, and calculating the remainder to MgO.

Standard Methods of

CHEMICAL ANALYSIS OF SODA-LIME GLASS[1]

A.S.T.M. Designation: C 169 – 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 169; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These methods for the chemical analysis of glass cover procedures for use in the referee analysis and in the routine analysis of soda-lime glasses containing the usual constituents of such glasses and not more than 0.5 per cent of fluorine, 2.0 per cent of barium oxide (BaO), 2.0 per cent of boric oxide (B_2O_3), 0.10 per cent of phosphorus pentoxide (P_2O_5), 0.10 per cent of zinc oxide (ZnO), 0.05 per cent of antimony oxide (Sb_2O_3), and 0.05 per cent of lead oxide (PbO). These methods do not preclude the use of other methods that yield results within permissible variations. In any case, the analyst should check the procedure and technique that are employed by means of a National Bureau of Standards standard sample having a composition comparable with that of the material under test. A list of these standard samples is given in the Bureau's Supplement to *Circular C398*.

(*b*) The analytical procedures appear in the following order:

	Sections
Procedures for Referee Analysis:	
Silicon Dioxide	6
Ferric Oxide	7 and 8
Determination of BaO, $Al_2O_3 + P_2O_5$, CaO, and MgO	9 to 12
Sodium Oxide and Potassium Oxide	13 to 17
Boric Oxide	18 to 20
Sulfur Trioxide	21 and 22
Procedures for Routine Analysis:	
Silicon Dioxide	23
Determination of BaO, R_2O_3, CaO, MgO, Na_2O, and K_2O	24 to 31
Boric Oxide	32 and 33
Fluorine	34 and 35
Sulfur Trioxide	36

Reagents

2. (*a*) *Purity of Reagents.*—All reagents shall be free of such amounts of impurities as would endanger the test in question. Reagents conforming to the specifications of the Committee on Analytical Reagents of the American Chemical Society are recommended. In all cases, blank determinations on all reagents used shall be carried through each step of the procedure and the final result corrected as may be indicated. The term "water" as used in these methods refers only to distilled water.

(*b*) *Concentration of Acids and Ammonium Hydroxide.*—Unless otherwise stated, the concentrated reagents, as furnished by the manufacturer, are to be used. For example, hydrochloric acid or HCl refers to acid of specific

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, these methods were published as tentative from 1941 to 1943, being revised in 1943.

gravity 1.19, sulfuric acid or H_2SO_4 refers to acid of specific gravity 1.84, and ammonium hydroxide or NH_4OH refers to the reagent of specific gravity 0.90. Diluted acids and ammonium hydroxide are designated as follows: diluted HCl (5:95) means 5 volumes of the concentrated acid of specific gravity 1.19 diluted with 95 volumes of water, and diluted NH_4OH (5:95) means 5 volumes of concentrated ammonium hydroxide of specific gravity 0.90 diluted with 95 volumes of water.

Filter Papers

3. Throughout these methods, filter papers will be designated as "loose" or "tight," without naming brands or manufacturers. "Loose papers" will mean the type of ashless papers that are generally used by analysts for filtering aluminum hydroxide or large amounts of silica. "Tight papers" will mean such ashless papers as are generally used by analysts for filtering barium sulfate.

Preparation of Sample for Analysis

4. The sample for analysis shall pass a No. 60 (250-micron) sieve and shall be dried at 105 to 110 C. It should be noted that soda-lime glasses may absorb and fix carbon dioxide and water during the grinding process and in storage. If the composition of the unground glass is desired, determinations of the loss on ignition at 1000 C. shall be made on an appropriate piece of the unground glass and on the powdered sample. From the two results obtained, the amount of carbon dioxide and water absorbed by the powdered glass can be calculated and the proper correction shall be made.

Probable Accuracy of Results

5. (*a*) The probable accuracy of results that can be expected by the use of the procedures described in Sections 6 to 36 is shown in the following tabulation:

Constituent	Probable Accuracy of Results, per cent: Referee Analysis	Routine Analysis
SiO_2	±0.1	±0.1 in absence of B_2O_3; +0.1 to +0.2 in presence of B_2O_3
Fe_2O_3	±0.005	..
BaO	−0.02	±0.05
$Al_2O_3 + P_2O_5$	±0.05	..
CaO	±0.05	±0.05
MgO	±0.05	±0.05
Na_2O	±0.2	±0.2
K_2O	±0.03	±0.05
B_2O_3	±0.05	±0.05
SO_3	±0.03	±0.05
"R_2O_3"	...	±0.05 (Al_2O_3 less than 1 per cent) to ±0.1 (Al_2O_3 more than 1 per cent)

(*b*) It is recommended that *reported* results be rounded off as follows:

Percentage	Number of Significant Figures Retained After Rounding Off
1 to 100	3
0.1 to 0.9	2
0.01 to 0.09	1 or 2
Under 0.01	1

(*c*) *Recorded* results should be carried to one more significant figure than required in Paragraph (*b*).

PROCEDURES FOR REFEREE ANALYSIS

SILICON DIOXIDE

Procedure

6. (*a*) Transfer 0.5000 g. of the prepared sample (Section 4) and 0.50 g. of Na_2CO_3 to a 75-ml. platinum dish,[3] and intimately mix the contents by means of the flattened end of a glass rod. Brush the mixture into the center of the dish, flatten the charge so that it covers a space about 3 cm. in diameter, and then cover it as evenly as possible with an additional 0.50 g. of Na_2CO_3. Heat gradually at first (preferably over a low flame) and finally at the temperature

[3] Dishes such as are used in the determination of alkalies are satisfactory, but special long-lip 75-ml. dishes of platinum alloyed with 3.5 per cent of rhodium are preferable.

required to give a clear melt. Maintain at this temperature for 10 min. Remove the dish from the source of heat, and cover it to prevent loss of small pieces of the solidified melt that might be ejected during cooling. A platinum cover may be used during the fusion, but this is not necessary, since no spattering occurs.

(*b*) Add 20 ml. of diluted HCl (1:1) to the cooled melt, cover the dish, and digest on the steam bath until disintegration is complete. If desired, the cooled melt may be digested in water before the acid is added. The action of the acid can be hastened by occasionally crushing the layer of insoluble matter that tends to cover the unattacked portion of the fused mass. As soon as disintegration is complete, crush all flakes of solid matter with the flattened end of a glass rod. Evaporate to dryness on the steam bath, cool, drench the dry residue with 5 ml. of HCl, and then add 15 ml. of warm water. Digest on the steam bath for a few minutes, and filter through a loose 9-cm. filter paper. Wash the dish, residue, and filter paper with ten 3-ml. portions of hot diluted HCl (2:98), but make no attempt to transfer all of the residue from the dish to the paper. Place the filter containing the residue in the platinum dish in which the fusion and dehydration were made, and evaporate the filtrate to dryness on the steam bath in another dish, preferably of platinum. Heat the residue at 105 to 110 C. for 15 min. Cool, drench the dry residue with HCl, dilute, filter through a small, tight filter paper, and wash as before. Transfer all the residue obtained in the second dehydration to the paper, and then place this paper with the paper containing the first residue in the platinum dish in which the fusion was made.

(*c*) Ignite the contents of the dish slowly at first and finally at approximately 600 C. until the carbon is gone. Add 3 or 4 drops of diluted H_2SO_4 (1:1) if a high nonsilica residue is expected, and ignite slowly at first and finally for 30 min. to 1 hr. at 1200 C. Cool in a desiccator, and weigh. Repeat ignition to constant weight. Treat the ignited residue with a few drops of diluted H_2SO_4 (1:1) and about 10 ml. of HF. Evaporate the volatile constituents on the steam bath, drive off the H_2SO_4 by heating over a free flame, and finally ignite the residue for 1 to 2 min. at 1200 C. The difference between the first and second weights, with a proper correction for a blank for the reagents, represents the weight of SiO_2 in the sample.

(*d*) *Calculation.*—Calculate the percentage of SiO_2 as follows:

$$SiO_2, \text{ per cent} = \text{wt. of } SiO_2 \times 200$$

NOTE.—The small amounts of fluorine that may be present in these glasses may cause a small but negligible negative error in the results for SiO_2, and the B_2O_3 may cause a small but negligible positive error.

FERRIC OXIDE

Reagents

7. (*a*) *Potassium Dichromate (0.005 N).*—Recrystallize, three times, the purest grade of $K_2Cr_2O_7$ obtainable. Dry the crystals at 150 C., grind to a fine powder, and dry at 200 C. until constant weight is attained. Dissolve 2.4516 g. of the recrystallized salt in water and dilute to exactly 10 liters. One milliliter of exactly 0.005 *N* $K_2Cr_2O_7$ represents 0.000399 g. of Fe_2O_3.

(*b*) *Stannous Chloride Solution.*—Dissolve 150 g. of $SnCl_2 \cdot 2H_2O$ in 100 ml. of HCl and dilute to 1000 ml. with water. Keep a few pieces of metallic tin in the bottle.

Procedure

8. Transfer 10 g. (Note) of the prepared sample (Section 4) to a 200-ml.

platinum dish. Moisten the sample with water, and add 50 ml. of diluted H_2SO_4 (1:1). Add cautiously 100 ml. of HF, mix thoroughly by stirring with a platinum rod or spatula, and evaporate to about 30 ml. on a steam or sand bath. Add 50 ml. of HF and evaporate to fumes of H_2SO_4. To the gently fuming solution, add cautiously, drop by drop, a few drops of HNO_3 to destroy organic matter. Cool, rinse the walls of the dish with water, and again heat to strong fumes of H_2SO_4 in order to expel all HNO_3. Cool the dish and contents, and add 100 ml. of water. Heat until soluble salts are in solution, and add strips of iron-free magnesium ribbon to precipitate platinum introduced during the decomposition of the sample. The treatment with magnesium may be done conveniently by wrapping the ribbon around the end of the glass stirring rod. The addition of sufficient magnesium is indicated when the ferric iron has been completely decolorized. After all the magnesium has been dissolved, boil for a few minutes, filter if platinum has separated, and wash the paper with hot water. Adjust the volume to 50 ml. Oxidize any reducing substances that may be present by adding 0.1 *N* $KMnO_4$ until a permanent pink coloration is produced. Add 50 ml. of HCl, heat to boiling, and reduce the iron with the minimum amount of a solution of $SnCl_2$. Titrate electrometrically with standard 0.005 *N* $K_2Cr_2O_7$, using a Roberts electrometric titration apparatus[4] or equivalent to determine the potential. The volume of standard $K_2Cr_2O_7$ necessary to effect oxidation of the ferrous iron is the volume required in passing from the first point of inflection as shown by the potentiometer reading, which indicates the oxidation of residual $SnCl_2$ and initial oxidation of the ferrous iron, to the second point of inflection, which indicates the complete transformation of the iron to the ferric condition. The points of inflection are best determined by means of a graph in which the volumes of $K_2Cr_2O_7$ used are plotted against the resulting electromotive force.

NOTE.—This procedure is satisfactory for determining iron up to a total of 10 mg. of Fe_2O_3. For larger quantities, the size of the sample should be so reduced that the 10 mg. is not exceeded. This may be accomplished by using a smaller sample of the glass, or preferably, by taking an appropriate aliquot portion of the solution obtained after decomposition of the 10-g. sample.

DETERMINATION OF BaO, Al_2O_3 + P_2O_5, CaO, AND MgO

Preparation of the Solution and Determination of BaO

9. (*a*) Transfer 2.50 g. of the prepared sample (Section 4) to a 250- to 300-ml. platinum dish. Thoroughly moisten the sample with 20 ml. of diluted H_2SO_4 (1:1) and add slowly, while stirring constantly with a platinum rod or spatula, about 30 ml. of HF. Evaporate to fumes of H_2SO_4, and add a few drops of HNO_3 to the hot solution to destroy organic matter. Repeat the hydrofluoric acid treatment, using 20 ml. of HF. When the acid is fuming strongly, cool the dish and contents, rinse the walls of the dish with water, repeat the evaporation to fumes of H_2SO_4, and continue the fuming for 10 min. Cool, add 250 ml. of diluted HCl (1:99), and heat until soluble salts have dissolved. Cool, and allow to stand 2 hr. or longer. Filter through a tight paper, wash the residue and paper with hot water, and reserve the filtrate and washings. Ignite the insoluble residue in platinum, fuse with 3 g. or less of Na_2CO_3, and leach the melt with hot water. Filter through a loose paper, wash with hot water, and reserve

[4] J. C. Hostetter and H. S. Roberts, "Electrometric Titrations, with Special Reference to the Determination of Ferrous and Ferric Iron," *Journal*, Am. Chemical Soc., Vol. 41, p. 1337 (1920); "Electrometric Determination of Iron," *Journal*, Am. Ceramic Soc., Vol. 10, April, 1927 (p. 100 of the *Bulletin*).

the filtrate and washings. Dissolve the insoluble matter in the crucible, in the beaker, and on the filter paper in 25 ml. of hot diluted HCl (5:95). Wash the beaker, crucible, and filter thoroughly with hot water, dilute the solution to 200 ml., heat to boiling, and add 4 ml. of diluted H_2SO_4 (1:1). Digest on the steam bath for about 1 hr., cool, and allow to stand 2 hr. or longer. Filter through a tight paper, and wash thoroughly with hot water. Reserve the filtrate and washings. Ignite the precipitate slowly in a porcelain or platinum crucible until the carbon is burned; then heat at about 1000 C. for 15 min. Cool in a desiccator and weigh.

(*b*) *Calculation.*—Calculate the percentage of BaO as follows:

$$\text{BaO, per cent} = \text{wt. of } BaSO_4 \times 26.28$$

Determination of $Al_2O_3 + P_2O_5$

10. (*a*) Combine the three reserved filtrates (Section 9 (*a*)) (from the first precipitation of $BaSO_4$, from the leaching of the sodium carbonate fusion, and from the second precipitation of $BaSO_4$). Neutralize the excess acid with NH_4OH and then add 3 ml. of HCl. Adjust the volume to 300 ml. and saturate the solution with H_2S. Digest, preferably overnight, filter through a tight paper, wash with diluted H_2SO_4 (1:99) saturated with H_2S, and discard the sulfide precipitate. Boil the filtrate to expel H_2S, oxidize with bromine water, boil off the excess of bromine, and precipitate with NH_4OH, using methyl red as the indicator. Filter, and allow the solution to drain. Reserve the filtrate. Transfer the paper and precipitate to the beaker, and add 10 ml. of diluted HCl (1:1). Stir the paper to a pulp, warm until the hydroxides are dissolved, and add 150 ml. of water. Heat the solution to boiling, and precipitate with NH_4OH as before. Filter, and wash the paper and precipitate thoroughly with a hot neutral solution of NH_4Cl (2 per cent). Combine the two filtrates, acidify, and reserve them for the determination of calcium and magnesium (Sections 11 and 12). Transfer the paper and precipitate to a 400-ml. beaker, and add 20 ml. of HNO_3 and 10 ml. of H_2SO_4. Cover, heat cautiously until the solution begins to blacken, and then add HNO_3 drop by drop, allowing each drop to flow down the beaker wall, until all carbonaceous matter has been destroyed. Heat to strong fumes of H_2SO_4, cool, rinse the cover glass and beaker walls, and again heat to fumes of H_2SO_4. Cool, add 150 ml. of water, and heat to dissolve any anhydrous sulfates. Cool the solution, transfer to a 200-ml. volumetric flask, and dilute to the mark. Mix thoroughly, and divide the solution into two 100-ml. aliquot portions.

(*b*) *Determination of Al_2O_3, P_2O_5, Fe_2O_3, TiO_2, ZrO_2, and V_2O_5 (If the glass contains chromium, Cr_2O_3 will be included here).*—Dilute one of the 100-ml. aliquot portions to 250 ml., heat to boiling, and precipitate with NH_4OH, using methyl red as the indicator. Filter, and wash paper and precipitate thoroughly with a hot, neutral solution of NH_4NO_3 (2 per cent). Discard the filtrate. Ignite the paper and precipitate in a platinum crucible weighed with cover. Moisten the ignited residue with water, then add 5 to 10 drops of diluted H_2SO_4 (1:1) and 5 ml. of HF. Evaporate to expel the excess of acids, and gradually increase the temperature until all H_2SO_4 has been expelled and the sulfates decomposed. Cover the crucible and ignite at approximately 1100 C. Cool over a good desiccant, and weigh. Repeat the ignition until constant weight is obtained. The weight of the oxides multiplied by 80 represents the combined percentages of Al_2O_3, P_2O_5, Fe_2O_3, TiO_2, ZrO_2, V_2O_5, and Cr_2O_3.

(*c*) *Determination of Fe_2O_3, TiO_2, ZrO_2, and V_2O_5.*—Dilute the other 100-ml.

aliquot portion (Paragraph (*a*)) to 200 ml., add 15 ml. of H_2SO_4, and cool the solution to 10 C. Add slowly, while stirring constantly, a cold solution of cupferron (6 per cent) until no further precipitation occurs. (Prepare the cupferron solution by dissolving 6 g. of cupferron reagent in cold water immediately before use. Filter, and use the clear solution.) Stir in a little macerated filter paper, allow the precipitate to settle, filter through a tight paper, and wash the paper and precipitate thoroughly with cold diluted H_2SO_4 (1:9) containing 1.5 g. of cupferron per liter. Drain the paper and precipitate, and transfer to a platinum crucible weighed with cover. Dry the precipitate cautiously at about 60 C., and ignite slowly until all carbonaceous matter is destroyed. Cool the crucible, and treat with H_2SO_4 and HF to remove any SiO_2. Evaporate to dryness and then ignite at approximately 1100 C. Cool over a good desiccant, and weigh. Repeat the ignition until constant weight is obtained. The weight of the oxides multiplied by 80 represents the combined percentages of Fe_2O_3, TiO_2, ZrO_2, and V_2O_5.

(*d*) *Determination of* $Al_2O_3 + P_2O_5$.—The percentage of oxides obtained from the ammonium hydroxide precipitation of the first aliquot portion (Paragraph (*b*)) minus the percentage of oxides obtained from the cupferron precipitation of the second aliquot portion (Paragraph (*c*)) represents the percentage of $Al_2O_3 + P_2O_5$. Chromium is not precipitated by cupferron and will be counted with the $Al_2O_3 + P_2O_5$ if the glass contains chromium.

If the glass contains P_2O_5, some of it will be found in the ignited oxides obtained in accordance with Paragraph (*b*). To test for P_2O_5, fuse the ignited oxides with Na_2CO_3, dissolve the cooled melt in diluted HNO_3, and add molybdate reagent. If a precipitate of phosphomolybdate appears, filter, determine the P_2O_5 by the customary alkalimolybdate method, and deduct from the weight of the ignited $Al_2O_3 + P_2O_5$.

Determination of CaO

11. (*a*) Evaporate to 150 ml. the acidified and combined reserved filtrates obtained in the NH_4OH precipitations (Section 10(*a*)) and transfer to a 200-ml. volumetric flask. Dilute to the mark and mix thoroughly. To a 100-ml. aliquot portion add two drops of methyl red (0.02 per cent) and 1 g. of oxalic acid. Heat the solution to boiling, and slowly add NH_4OH until the solution is alkaline. Digest for 1 hr. on the steam bath, cool to room temperature, filter on a small, tight paper, and wash the precipitate and paper two or three times with a cool, neutral solution of ammonium oxalate (0.1 per cent). Reserve the filtrate and washings. Return the paper and precipitate to the precipitating vessel, add 10 ml. of diluted HCl (1:1), and stir the paper to a pulp. Dilute the solution to 200 ml., and add 0.2 g. of oxalic acid. Heat the solution to boiling, and slowly add NH_4OH until the solution is alkaline. Digest, filter, and wash as before. Combine the filtrate and washings with the reserved filtrate and washings, and acidify with HCl. Transfer the paper and precipitate to a platinum crucible (weighed with cover), and heat until carbon has been destroyed. Cover tightly, ignite for about 5 min. at 1200 C., cool over a good desiccant, and weigh as CaO. The crucible should be reheated and the weight checked because of possible absorption of moisture and CO_2 during the first weighing.

(*b*) *Calculation.*—Calculate the percentage of CaO as follows:

$$\text{CaO, per cent} = \text{wt. of CaO} \times 80$$

Determination of MgO

12. (*a*) Evaporate to 150 to 200 ml. the filtrates from the ammonium oxalate precipitations (Section 11(*a*)). Cool the solution, and add 1 g. of $(NH_4)_2HPO_4$. Stir the solution vigorously, slowly add NH_4OH until the solution is alkaline, and then add 10 ml. of NH_4OH. Allow the solution to stand 4 hr. or overnight. Filter through a tight paper, wash the beaker, paper, and precipitate moderately with diluted NH_4OH (5:95), and discard the filtrate. Place the beaker under the funnel, and dissolve the precipitate in 25 to 50 ml. of hot, diluted HCl (1:9). Add 0.1 g. of $(NH_4)_2HPO_4$, dilute to 75 ml., cool, and then add NH_4OH drop by drop, while stirring constantly, until the solution is alkaline. Finally add 5 ml. in excess, and let stand 4 hr. or overnight. Filter through a tight paper, transfer all the precipitate to the paper, and wash with cool diluted NH_4OH (5:95). Dry the precipitate and paper in a platinum crucible (weighed with cover), char the paper slowly, and burn off the carbon by gradually increasing the temperature. Cover the crucible, and ignite at 1000 to 1100 C. for 30 min. Cool in a desiccator, and weigh. Repeat the ignition to constant weight.

(*b*) *Calculation.*—Calculate the percentage of MgO as follows:

$$\text{MgO, per cent} = \text{wt. of } Mg_2P_2O_7 \times 29.0$$

SODIUM OXIDE AND POTASSIUM OXIDE

Reagents

13. (*a*) *Ammonium Chloride.*—The reagent grade of NH_4Cl is satisfactory if a test shows that 1 g. yields not more than 0.1 mg. of nonvolatile residue when the NH_4Cl is volatilized by heating and the residue is ignited at 700 to 800 C. If the reagent grade is not satisfactory, sublime it slowly, crush the sublimed material in an agate mortar, and store the fine powder in a well-stoppered bottle.

(*b*) *Calcium Carbonate.*—The reagent grade of $CaCO_3$ is usually unsatisfactory. Dissolve the purest $CaCO_3$ obtainable in diluted HCl (1:3), precipitate with NH_4OH and $(NH_4)_2CO_3$, wash thoroughly with hot water, dry at about 105 C., and store in a well-stoppered bottle.

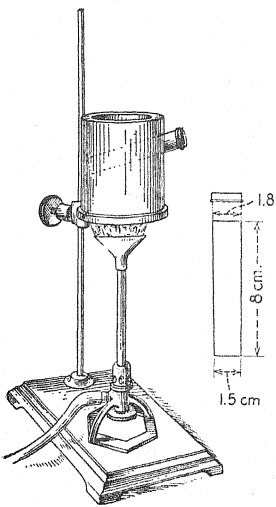

FIG. 1.—Apparatus for Determining Sodium Oxide and Potassium Oxide.

(*c*) *Chloroplatinic Acid Solution.*—Dissolve 15 g. of chloroplatinic acid ($H_2PtCl_6 \cdot 6H_2O$) in 50 ml. of water containing 5 ml. of diluted HCl (1:1). One milliliter will contain about 0.1 g. of platinum; 1.31 ml. of such a solution is required for 0.1 g. of KCl, and 1.68 ml. for 0.1 g. of NaCl.

Apparatus

14. *Platinum Crucible.*—A platinum crucible of suitable size for treating 0.5 g. of sample is 8 cm. in length, 1.8 cm. in diameter at the mouth, and 1.5 cm. in diameter at the bottom, and has a weight of about 25 g. The crucible and the chimney to hold it are shown in Fig. 1.

Determination of NaCl and KCl

15. (*a*) Transfer 0.5000 g. of the prepared sample (Section 4) and 0.50 g. of NH_4Cl to a large, smooth agate mortar placed on a piece of glazed paper. Grind with a pestle until the sample and the NH_4Cl are thoroughly mixed. Next add, in several portions, nearly all of 4 g. of $CaCO_3$, and mix very thoroughly in the mortar. Line the bottom of the crucible with a little of the $CaCO_3$, and transfer the mixture to the crucible by the aid of a spatula having a blade that is somewhat flexible and not too broad. Use the rest of the $CaCO_3$ for rinsing the mortar and pestle, and transfer the rinsings also. All this should be done over the piece of glazed paper.

(*b*) Cap the crucible, tap it gently to make the powder settle, and place it in an inclined position in a clay cylinder (Fig. 1) or through a hole in a piece of stout asbestos board clamped at a slight angle. Heat the part within the cylinder or projecting through the board by a fishtail flame placed considerably beneath the crucible. Continue gentle heating for about 15 min., or until the odor of ammonia is no longer perceptible. Do not heat so that NH_4Cl escapes. Replace the flame by one or two burners of any type that will give the proper temperature, and heat at about 1000 C. for 30 to 60 min.

(*c*) Cool, transfer the sintered cake to a 12-cm. porcelain dish, pour hot water into the crucible, and digest until all remaining matter can be washed out or until it is thoroughly extracted. In most instances, the entire sintered cake can be loosened from the crucible by lightly tapping. Slake the cake in the dish with 1 to 2 ml. of water at first, then add 50 ml. more, until thoroughly disintegrated. If the cake clings to the crucible, the slaking must be done without removing it. When the cake has disintegrated and the solution is saturated with $Ca(OH)_2$, filter by decantation upon a 9-cm. filter and let the filtrate run into a capacious dish, preferably of platinum. Keep as much as possible of the residue in the porcelain dish. Add 50 ml. more of hot water, break up any lumps by gentle pressure with a pestle, let settle, and again decant. Repeat the extraction at least three more times. Wash the residue in the paper and dish with a saturated solution of $Ca(OH)_2$ free of sodium and potassium. The final residue, which is to be discarded, should dissolve completely in HCl and will contain very little, if any, alkalies if the work has been carefully done.

(*d*) To the filtrate and washings, add a few drops of NH_4OH and then an excess of solid $(NH_4)_2CO_3$. The presence of an excess can be determined by allowing the precipitate of $CaCO_3$ to settle and then adding small pieces of $(NH_4)_2CO_3$ and noting whether further precipitation takes place. Heat until effervescence ceases, and boil carefully for at least 3 min. to expel CO_2. Rinse and remove the cover, filter into a 1-liter casserole, and wash the dish, paper, and residue with five 10-ml. portions of hot water. Reserve the filtrate. Dissolve the precipitate in as little diluted HCl (1:4) as possible, and reprecipitate with $(NH_4)_2CO_3$ as before. Filter, and add the filtrate to the reserved filtrate.

(*e*) Evaporate the combined filtrates to dryness, and heat gently to remove ammonium salts. Dissolve the residue in 25 ml. of water, add a few drops of NH_4OH, heat to boiling, add $(NH_4)_2C_2O_4 \cdot H_2O$ (saturated solution) until an excess of about 5 drops is present, and let stand for 2 hr. or preferably overnight.[5] Filter through a tight paper to remove the calcium oxalate, catch the filtrate in a 100-ml. platinum dish, and wash paper and residue with a cold 0.1 per cent solution of $(NH_4)_2C_2O_4 \cdot H_2O$.

(*f*) Evaporate the filtrate and washings to dryness, cover the dish, and heat at 110 to 120 C. Cautiously ignite, with cover on at first, until ammonium salts have been volatilized. Cool, rinse, and remove the cover glass, and dissolve the residue in a little water. Add a few drops of HCl to decompose any alkali carbonate that may have been formed by action of the ammonium oxalate during the ignition. Again evaporate to dryness. Add 5 ml. of HCl and 5 ml. of methyl alcohol. Cautiously evaporate to dryness to drive off any boron that may be present. Cover the dish, heat in an oven at 135 to 140 C., and ignite very gently (until salts just begin to melt) to constant weight.

(*g*) Dissolve the salts in hot water, filter through a small ashless filter paper, and wash with hot water. Ignite the paper in the dish, cool, weigh, and subtract the second weight from the first in order to obtain the weight of NaCl + KCl.

Determination of K_2O

16. (*a*) The following procedure shall be carried out in an atmosphere free of ammonia and the fumes of ammonium salts: Dissolve the mixed chlorides (Section 15) in a little water, transfer to a porcelain dish, and add enough chloroplatinic acid to react with all of both the sodium and the potassium. Evaporate on the steam bath until the solution is syrupy but solidifies on cooling. Do not evaporate to dryness. Cool, drench the residue with ethyl alcohol (80 per cent by volume), and filter by decantation through a small paper. Wash by decantation with more of the alcohol, crushing the crystals with a small pestle or the widened and rounded end of a short glass rod. Dry the dish and paper to remove adhering alcohol completely.

(*b*) Dissolve the precipitate on the paper in hot water, catching the solution in a weighed platinum crucible or small platinum dish. Evaporate to dryness, and add the salt that is still in the porcelain dish. If the residue is large and lumpy, redissolve in water, and again evaporate to dryness. Cover and heat for 1 hr. at 130 C. in an oven (100 C. suffices for very small amounts of fine-grain precipitate). Cool, and weigh as K_2PtCl_6. Multiply by 0.194 to obtain the weight of K_2O and by 0.307 to obtain the corresponding weight of KCl.

Determination of Na_2O

17. Calculate the weight of sodium oxide by subtracting the weight of KCl obtained in Section 16 from the weight of NaCl + KCl, and multiplying the remainder by 0.530.

BORIC OXIDE

Apparatus

18. The apparatus, shown in Fig. 2, shall consist of the following: *A*, a U-tube containing mercury, used as a safety trap; *B*, a 500-ml. round-bottom distilling flask for methyl alcohol, containing a capillary "boiling tube" of

[5] If the material contains sulfates, these must be removed by adding a slight excess of $BaCl_2$ solution (10 per cent) to the water solution of the residue, heating to boiling, letting settle, and filtering. In this case, the solution must be treated with NH_4OH and $(NH_4)_2CO_3$ and filtered in order to remove the excess of barium before the ammonium oxalate is added.

3-mm. bore, the bore being sealed 10 mm. from the lower end; *C*, a 300-ml. round-bottom flask; *D*, a No. 4 (360-ml.) casserole; *E*, a glass condenser; *F*, a 200-ml. Erlenmeyer flask; and *G*, a U-tube containing water to prevent the escape of uncondensed methyl borate. The tube leading into flask *C* shall be flared slightly to avoid plugging by separated salts. The apparatus shall be assembled with glassware and tubing resistant to heat and chemicals.[6]

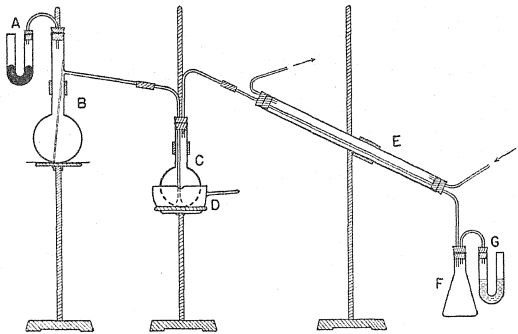

FIG. 2.—Apparatus for Distilling Boron.

Reagents

19. (*a*) *Methyl Alcohol.*—Alcohol free of boric acid and volatile organic acids shall be used. The more nearly anhydrous the alcohol, the better.

(*b*) *Mannite.*—Reagent grade, neutral.

(*c*) *Phenolphthalein Indicator.*—Dissolve 1 g. of phenolphthalein in 60 ml. of ethyl alcohol and dilute to 100 ml. with water.

(*d*) *Methyl Red Indicator.*—Dissolve 0.1 g. of methyl red in 60 ml. of ethyl alcohol and dilute to 100 ml. with water.

(*e*) *Calcium Chloride.*—Reagent grade, granular (8-mesh), anhydrous.

(*f*) *Boric Acid (0.1 N).*—Fuse pure boric acid in a platinum dish. While still warm, crush the melt and quickly place the fragments in a weighing tube. Dissolve 3.482 g. in 500 ml. of hot, recently boiled distilled water, cool, and dilute to exactly 1000 ml. Each milliliter of the solution contains 0.003482 g. of B_2O_3.

(*g*) *Sodium Hydroxide (approximately 0.1 N).*—Prepare the solution, as free of carbonates as possible, by diluting 6.5 ml. of a clear 50 per cent solution of NaOH with 1 liter of recently boiled distilled water. Standardize by titrating against the standard solution of boric acid exactly as described in Section 20.

(*h*) *Hydrochloric Acid (approximately 0.1 N).*—Prepare an approximately 0.1 *N* solution free of CO_2.

Procedure

20. (*a*) Mix 0.5000 g. of the prepared sample (Section 4) with exactly two times its weight of Na_2CO_3, and heat in a

[6] Pyrex glass or Kimble Glass No. N51a is satisfactory for this purpose. See *Industrial and Engineering Chemistry* (Anal. Ed.), Vol. 13, p. 419 (1941).

platinum crucible until a clear melt is obtained. Without removing it from the crucible, decompose the melt with diluted HCl (1:1) in calculated amount and added in small portions so as to avoid excessive frothing. While this is being done, the crucible should rest in a casserole, and the lid should be kept in place as much as possible. Toward the end, it may be necessary to heat a little, but care should be taken not to boil, since boric acid would be lost with the steam. Pour the solution into the flask *C*, Fig. 2, and rinse the crucible with a very small quantity of water.

(*b*) Add pure anhydrous $CaCl_2$, using about 1 g. for each milliliter of solution and dropping it through a paper funnel to keep the neck of the flask clean. Swirl the contents of the flask to allow the $CaCl_2$ to take up the water. Connect the flask to the apparatus, as shown in Fig. 2, and raise the casserole until the flask dips into the water but does not touch the bottom. Begin the distillation of alcohol from *B*, taking care that the "boiling tube" is functioning properly. After about 25 ml. of alcohol have condensed in *C*, heat the casserole with a small flame, keeping it hot enough to prevent condensation in the flask. When a distillate of 150 ml. has collected in flask *F*, replace the flask with an empty one, and continue the distillation.

(*c*) Add 1 drop of the phenolphthalein solution and 2 or 3 pellets of solid NaOH (about 0.25 g.) to the first distillate, stopper, and swirl until the NaOH has dissolved. The solution should be definitely alkaline; if not, add more NaOH. Transfer the contents of the flask to a platinum dish and heat gently on a steam bath to remove alcohol. Meanwhile a second distillate of 150 ml. will have collected. Add the contents of the protecting U-tube, make alkaline as with the first distillate, and transfer the solution to the platinum dish. Evaporate to dryness and dissolve the residue in about 10 ml. of hot water.

(*d*) Transfer the solution to a 200-ml. Erlenmeyer flask, and rinse with a minimum of hot water. The volume now should not exceed 25 ml. Add 5 drops of the methyl red solution (paranitrophenol may be substituted if desired) and then diluted HCl (1:1) drop by drop until the solution is acid, taking care not to add more than 1 drop in excess. Heat quickly to boiling and continue the boiling for 15 sec. Cool, add 5 drops of the phenolphthalein solution, and then drop by drop, add 0.1 *N* NaOH, until the red tint of the methyl red is discharged. One drop of 0.1 *N* HCl should restore the color, and 1 drop of 0.1 *N* NaOH should discharge it. Now add 1 g. of mannite, note the reading of the burette, and titrate until the phenolphthalein end point appears. Again add 1 g. of mannite and, if the color disappears, continue the titration until the color returns. Continue this process until the addition of 1 g. of mannite does not discharge the phenolphthalein end point.

(*e*) *Calculation.*—Correct the volume of 0.1 *N* NaOH required in passing from the methyl red end point to the phenolphthalein end point by subtracting the volume required in a blank run. Calculate the percentage of B_2O_3 as follows:

$$B_2O_3, \text{ per cent} = VA \times 200$$

where:

V = corrected volume in milliliters of NaOH solution required for titration from the methyl red end point to the phenolphthalein end point, and

A = B_2O_3 equivalent of the NaOH solution.

NOTE.—Results are likely to be low by 0.05 to 0.10 per cent in glasses containing 1 to 2 per

cent of B_2O_3 unless the boron in the residue in the distilling flask is recovered. To make this recovery, the residue in the flask must be filtered off, washed moderately with water, ignited, fused, carried through the procedure, and the result corrected for the blank on the reagents.

SULFUR TRIOXIDE

Reagent

21. *Barium Chloride Solution (10 per cent).*—Dissolve 100 g. of $BaCl_2 \cdot 2H_2O$ in 1000 ml. of water, allow to stand for 24 hr., and filter if the solution is not clear.

Procedure

22. (*a*) Transfer 5.00 g. of the prepared sample (Section 4) to a platinum dish, and add 25 ml. of water and 50 ml. of HF. Digest for 15 min. on the steam bath, and add 1 ml. of HNO_3, 15 ml. of $HClO_4$ (60 per cent), and 0.2 g. of $Mg(NO_3)_2 \cdot 6H_2O$. Evaporate on the steam bath until the HNO_3 and HF have been volatilized, and then heat on a hot plate at a low temperature so that light fumes of $HClO_4$ are evolved for about 5 min. Cool, wash the inside surface of the dish with a jet of water, and add 10 ml. of $HClO_4$ (60 per cent). Heat on a hot plate at a low temperature until nearly all of the $HClO_4$ has been evaporated.

(*b*) Cool, add 25 ml. of diluted HCl (5:95), and digest on the steam bath for 15 min. Add 150 ml. of hot water and 10 ml. of $BaCl_2$ solution. Digest on the steam bath for 1 hr. or more, and allow to stand at room temperature for 2 hr. or overnight. Filter through a tight paper, and wash with hot diluted HCl (1:99).

(*c*) Ignite the paper and precipitate slowly in a platinum crucible until all carbon is eliminated. Cool, and fuse the residue with 3 g. of Na_2CO_3. Dissolve the cooled melt in a small excess of diluted HCl (1:3), and digest the acid solution on the steam bath for 15 min. Then neutralize the excess acid with NH_4OH, using litmus as the indicator. Add 1 ml. of HCl, dilute the solution to 100 ml., heat to boiling, and add 5 ml. of $BaCl_2$ solution. Digest on the steam bath for 1 hr., and allow to stand at room temperature for 2 hr. or overnight. Filter, and wash as before. Ignite the paper and precipitate slowly at first until the carbon is eliminated, and finally at 1000 C. for 30 min. Cool and weigh.

(*d*) *Calculation.*—Calculate the percentage of SO_3 as follows:

$$SO_3, \text{ per cent} = \text{wt. of } BaSO_4 \times 6.86$$

PROCEDURES FOR ROUTINE ANALYSIS

These procedures for routine analysis admit of considerable variation, especially as regards the preparation of a master solution and the use of aliquot portions for several of the constituents. The procedures are designed for use under average laboratory conditions where it may be assumed that (*a*) several samples are to be analyzed simultaneously, with only a moderate supply of platinum ware, (*b*) all determinations are to be completed within one working day, and (*c*) the accuracy need not quite equal that obtainable with the referee methods.

Under certain conditions it may be of advantage to modify one or more of the steps in the procedure. For example:

(*1*) If the supply of platinum ware is not a factor, and if certain of the determinations are desired in a minimum of time, separate samples (0.1 g. and 0.5 g., respectively) may be decomposed for Na_2O and K_2O. In that case, a third sample (1.0 g.) is taken for BaO, R_2O_3, etc., and here decomposition may be effected by either HF and $HClO_4$ or HF and H_2SO_4, as desired. Under these conditions it becomes unnecessary to prepare a master solution, and it is possible to complete several of the determinations in an unusually short period of time.

(2) With glasses containing very small quantities of elements such as barium or aluminum, greater accuracy may be obtained by the use of a larger sample (2 g. or more), and the filtrate may be diluted to a definite volume at any desired point in the analysis and a suitable aliquot portion taken for the remaining determinations.

SILICON DIOXIDE

Procedure

23. (*a*) Intimately mix 0.5000 g. of the prepared sample (Section 4) with 1 g. of Na_2CO_3 in a 75-ml. platinum evaporating dish. Heat gradually at first over a flame, or in a muffle, and finally at a temperature high enough to give a *clear* melt. Allow the melt to solidify in a thin layer covering the bottom of the dish. Add about 10 ml. of diluted HNO_3 (1:1), and place the dish (covered) on a steam bath until all of the carbonates are decomposed. If desired, the cooled melt may be digested in water before the acid is added. Remove the dish, rinse the cover glass with a small quantity of water, and allow the solution to evaporate to dryness. Add 10 to 15 ml. of $HClO_4$ (60 per cent), and transfer the dish to a hot plate at about 200 to 220 C. Heat until fumes are evolved freely, then cover with a watch glass, and allow fuming to continue for 20 min. Sufficient $HClO_4$ should be present to prevent the contents of the dish from becoming dry. Remove the dish, cool, and dilute the contents with about 50 ml. of hot water. Stir to dissolve soluble salts, place the dish on a steam bath, and digest for 10 min. Pour the supernatant solution through a loose filter paper and flood the residue with about 10 ml. of hot diluted HCl (2:98). Stir and grind the solid lumpy material with a glass rod; then pour the solution through the filter. Transfer the precipitate completely to the filter by means of hot diluted HCl (2:98), using a rubber policeman, and continue washing the paper and precipitate with eight to ten small portions of the diluted HCl.

If desired the first dehydration can be made as described in the Procedures for Referee Analysis (Section 6 (*a*)); in this case add 10 to 15 ml. of $HClO_4$ (60 per cent) before the second evaporation. Evaporate the filtrate and washings in a 600-ml. beaker of heat-resistant glass[6] on a hot plate to a small volume; then heat at a reduced rate until copious fumes of $HClO_4$ appear. Rinse the inside of the beaker by means of 10 ml. of $HClO_4$ added from a pipette. Cover the beaker and continue heating for about 10 min. while dense fumes of $HClO_4$ are evolved.

(*b*) Allow the beaker to cool, and rinse the inside surface with about 50 ml. of distilled water. Digest for 10 min. on a water bath; then filter through a tight paper. Transfer the small precipitate completely to the paper, and wash paper and precipitate with ten portions of hot diluted HCl (2:98). Place both papers and precipitates in an untared 20-ml. platinum crucible, add 3 or 4 drops of diluted H_2SO_4 (1:1), and ignite slowly in a muffle furnace until the carbon is burned off and the residue is white. Cover and heat over a blast flame or in a muffle furnace at about 1200 C. for 20 min., cool in a desiccator, and weigh. Repeat ignition to constant weight. Moisten the residue with water, add about 10 ml. of HF and 1 drop of H_2SO_4, and evaporate to dryness on a hot plate. Cover the crucible and heat at approximately 1200 C. for 1 to 2 min. Cool in a desiccator and weigh. The loss in weight represents SiO_2.

(*c*) *Calculation.*—Calculate the percentage of SiO_2 as follows:

$$SiO_2, \text{ per cent} = \text{wt. of } SiO_2 \times 200$$

NOTE.—The net result obtained by this method is ordinarily slightly high (0.1 to 0.2 per cent) if B_2O_3 up to 2 per cent is present.

DETERMINATION OF BaO, R_2O_3, CaO, MgO, Na_2O, AND K_2O

Reagents

24. (*a*) *Standard Potassium Permanganate Solution.*—Dissolve 3.44 g. of $KMnO_4$ in distilled water, and dilute to 20 liters. This solution should stand for 3 to 4 months, and 1- to 3-liter portions of the clear supernatant liquid may then be siphoned off as required. Standardize against a solution containing a known amount of $CaCl_2$ by the procedure used in determining calcium (Section 28) rather than against sodium oxalate.

(*b*) *Standard Potassium Bromate (0.2 N) for MgO.*—Dissolve 120 g. of $KBrO_3$ in distilled water and dilute to 20 liters. Standardize against a known $MgCl_2$ solution by precipitating the quinolate as in the procedure for magnesium (Section 29), filtering, washing, dissolving with HCl, and titrating, using 0.1 *N* sodium thiosulfate for the back-titration.

(*c*) *Sodium Thiosulfate (0.1 N).*—Dissolve 25 g. of pure $Na_2S_2O_3 \cdot 5H_2O$ in recently distilled water and dilute to 1 liter. To obtain the equivalent of 1 ml. of thiosulfate in terms of standard bromate, add 10 ml. of bromate from a burette to 100 ml. of cool water containing 5 ml. of HCl; then add 10 ml. of KI (20 per cent), and titrate the liberated iodine with thiosulfate, using starch as indicator near the end point. The volume of bromate divided by the volume of thiosulfate (expressed to two decimal places) represents the volume of bromate equivalent to 1 ml. of thiosulfate.

(*d*) *Standard Magnesium Chloride Solution.*—Dissolve 1 g. of pure MgO in HCl and dilute to 2 liters. The exact concentration of MgO may be checked by a gravimetric determination (either as pyrophosphate or as quinolate ignited to MgO) on a 50-ml. aliquot portion.

(*e*) *8-Hydroxyquinoline Solution (5 per cent).*—To 5 g. of 8-hydroxyquinoline add 12 ml. of glacial acetic acid. Stir until dissolved, and dilute with 75 ml. of distilled water. Heat to 60 C. and stir until solution is complete, then filter into an amber bottle and dilute to 100 ml.

(*f*) *Potassium Iodide Solution.*—Dissolve 5 g. of KI in 25 ml. of distilled water and filter (if necessary). Store in an amber bottle. The solution deteriorates on long standing, and should be water-white when used.

(*g*) *Starch Indicator.*—Mix 2 g. of soluble starch with a little cold water and add to 100 ml. of boiling water. Cool and add 10 ml. of KI (25 per cent) and 10 ml. of NaOH (10 per cent). This solution keeps well over a fairly long period of time.

(*h*) *Zinc Uranyl Acetate Reagent for Na_2O.*—Transfer 100 g. of uranyl acetate, $UO_2(CH_3COO)_2 \cdot 2H_2O$, and 300 g. of zinc acetate, $Zn(CH_3COO)_2 \cdot 2H_2O$, to a bottle. Add 90 ml. of acetic acid (30 per cent) and then 810 ml. of warm water. Shake at intervals for a few hours. If the solution remains clear, add a few crystals of NaCl so as to saturate the solution with respect to sodium zinc uranyl acetate. Filter small portions of the reagent as required.

(*i*) *Chloroplatinic Acid Solution for K_2O.*—Dissolve 15 g. of chloroplatinic acid, $H_2PtCl_6 \cdot 6H_2O$, in 50 ml. of water containing 5 ml. of diluted HCl (1:1). One milliliter will contain about 0.1 g. of platinum, equivalent to 0.05 g. of K_2O.

(*j*) *Barium Chloride Solution (10 per cent).*—Dissolve 100 g. of $BaCl_2 \cdot 2H_2O$ in 1000 ml. of water, allow to stand for 24 hr., and filter if the solution is not clear.

Preparation of Solution

25. Transfer 2 g. of the prepared sample (Section 4) to a 75-ml. platinum dish, moisten with water, and add 1 ml.

of HNO_3, 10 ml. of $HClO_4$ (60 per cent), and about 25 ml. of HF (48 per cent). Evaporate on a steam bath to small volume, and then add about 10 ml. more of HF. Again evaporate to small volume. Transfer the dish to a hot plate (200 to 215 C.) and allow to fume until about one half of the $HClO_4$ is expelled. Examine for particles of undecomposed glass, and, if any are noted, add 5 ml. more of HF (48 per cent), and again evaporate to copious fumes. Cool the dish, and rinse down the inside surface with 5 ml. of $HClO_4$ (60 per cent) added from a pipette. Return the dish to a hot plate, and allow to fume briefly. Cool the dish, add about 0.5 g. of boric acid, and rinse down the inside of the dish with a little distilled water. Again evaporate to fumes, and continue the heating until most of the acid is eliminated, but not to the point where the residue appears dry. (A deep yellow to orange color at this point indicates that the glass contains chromium.) Add 50 ml. of hot water and 2 ml. of HCl and stir until the soluble salts are entirely dissolved. (The solution may be turbid if the glass contains both BaO and SO_3.) (Note). Rinse into a 200-ml. volumetric flask, cool to room temperature, and dilute to the mark. Mix thoroughly, and quickly pipette out the following aliquot portions:

(*1*) 100 ml. (1 g. of sample) into a 600-ml. beaker for BaO, "R_2O_3," CaO, MgO.

(*2*) 10 ml. (0.1 g. of sample) into a 50-ml. beaker for Na_2O.

(*3*) 50 ml. (0.5 g. of sample) into the platinum dish for K_2O.

NOTE.—Large amounts of BaO and SO_3 occurring together may cause difficulty through separation of $BaSO_4$. In such case, decompose a separate 1 g. sample of glass for each determination of BaO, R_2O_3, CaO, and MgO.

Determination of BaO

26. (*a*) Neutralize the reserved 100-ml. aliquot portion (Section 25) with NH_4OH, using methyl red as indicator. Then add 1 ml. of HCl. Dilute to about 150 ml., cover the beaker, heat to boiling, and add 10 ml. of diluted H_2SO_4 (1:9) from a pipette. Continue the boiling for 10 min.; then transfer to the steam bath and digest for 45 min. Filter through a tight paper, transfer the precipitate completely, and wash on the paper with four portions of warm water. Reserve the filtrate and washings for the determination of R_2O_3. Ignite the precipitate slowly in a tared porcelain crucible in a muffle furnace until the carbon is burned; then heat at about 1000 C. for 15 min. Cool in a desiccator, and weigh. (If the residue is not white, add a drop of H_2SO_4, heat gently until the acid is vaporized, then again ignite, cool, and weigh.)

(*b*) *Calculation.*—Calculate the percentage of BaO as follows:

$$\text{BaO, per cent} = \text{wt. of } BaSO_4 \times 65.7$$

Determination of R_2O_3

27. (*a*) Add 5 ml. of HCl to the filtrate from the BaO determination (Section 26) and boil for 5 min. to make sure that chromium is reduced to the trivalent state. Add diluted NH_4OH (1:1) drop by drop until the color of methyl red just changes to yellow, cover the beaker, and allow the contents to boil for 2 min. Filter immediately through a loose paper, rinse the beaker twice, and wash the precipitate on the paper four times with small quantities of hot, neutral ammonium chloride solution (2 per cent). Reserve the filtrate for the determination of CaO.

(*b*) Ignite the paper and precipitate in a tared platinum crucible, first in a muffle furnace until the carbon is eliminated, and finally for 10 min. at about 1200 C. Cool in a desiccator, and weigh.

(*c*) *Calculation.*—Calculate the percentage of R_2O_3 (including Al_2O_3, Cr_2O_3,

Fe_2O_3, TiO_2, ZrO_2, P_2O_5, and V_2O_5) as follows:

$$R_2O_3, \text{ per cent} = \text{wt. of precipitate} \times 100$$

Determination of CaO

28. (*a*) *Volumetric Method.*—Heat the reserved filtrate from the R_2O_3 separation (Section 27) to boiling in a covered beaker and add slowly 20 ml. of saturated ammonium oxalate solution from a pipette. Continue boiling for 5 min., transfer to a steam bath, and digest for 20 min. Filter through a tight paper, rinse the beaker two or three times with warm water, and wash the paper and precipitate four times with warm water (60 C.). Reserve the filtrate for the determination of MgO. Unfold the paper, and rinse the oxalate precipitate back into the original beaker by means of a stream of warm water. Discard the paper. Dilute to about 100 ml., add 20 ml. of diluted H_2SO_4 (1:1), heat nearly to boiling, and titrate with standard $KMnO_4$ solution to the first permanent pink. Calculate the percentage of CaO as follows:

$$\text{CaO, per cent} = VA \times 100$$

where:

V = volume in milliliters of $KMnO_4$ solution required for titration, and

A = CaO equivalent of $KMnO_4$ solution.

(*b*) *Gravimetric Method.*—Alternatively, the calcium oxalate may be ignited to the oxide and weighed as described in Section 11.

Determination of MgO

29. (*a*) Dilute to 500 ml. the filtrate reserved from the CaO separation (Section 28), add 10 ml. of 8-hydroxyquinoline solution (5 per cent) (1 ml. = 0.006 g. of MgO), and warm to 60 C. Add diluted NH_4OH (1:1) drop by drop, while stirring vigorously, until a precipitate starts to form, then add, drop by drop, an excess of 10 ml. of NH_4OH. Allow to settle for at least 20 min. Filter on a fritted glass crucible of medium porosity with suction. Transfer the precipitate by means of a rubber policeman, and wash four times with cold diluted NH_4OH (1:200). Discard the filtrate.

(*b*) *Volumetric Method.*—Dissolve the precipitate (Paragraph (*a*)) by means of 30 ml. of warm (60 C.) diluted HCl (1:1) added in small quantities and drawn through the filter with suction; wash thoroughly with hot water. Collect the solution in a 500-ml. Erlenmeyer flask, and dilute to about 100 ml. Cool the flask to about 20 C. Add 1 g. of KBr crystals, and then add standard $KBrO_3$ solution from a burette until a slight excess is present, as shown by the formation of a blue color when a drop of the solution is brought in contact with starch iodide paper. The excess of bromate should not exceed 2 to 3 ml. Allow to stand for about 1 min. to complete the bromination. Add 5 ml. of fresh KI solution (20 per cent) (resulting in a brown color or brown precipitate) and titrate with standard thiosulfate until most of the brown color has disappeared. Add 1 ml. of starch solution, and continue the titration to the disappearance of the blue color. Calculate the bromate equivalent of the thiosulfate, and subtract from the original volume of bromate to find the net volume equivalent to the MgO. Calculate the percentage of MgO as follows:

$$\text{MgO, per cent} = VA \times 100$$

where:

V = net volume in milliliters of bromate solution required for titration of the MgO, and

A = MgO equivalent of the bromate solution.

(*c*) *Gravimetric Methods.*—The following gravimetric methods may be used for the routine determination of MgO:

(*1*) The magnesium precipitate (Para-

graph (*a*)) may be dried to constant weight at 130 to 140 C. on the fritted glass filter and weighed as magnesium hydroxyquinolate ($Mg(C_9H_6NO)_2$), if desired.

MgO, per cent = wt. of $Mg(C_9H_6NO)_2 \times 12.9$

(*2*) The magnesium precipitate (Paragraph (*a*)) may be caught on a filter paper and converted to MgO by igniting gradually until the carbon is burned and finally heating at 1000 C.

MgO, per cent = wt. of MgO × 100

Determination of Na_2O

30. (*a*) Evaporate the reserved 10-ml. aliquot portion (Section 25) in a 50-ml. beaker to about 1 ml. on a hot plate. Cool, and add slowly 20 ml. of the zinc uranyl acetate reagent while stirring. Continue the stirring for 3 min. Allow the precipitate to settle for at least 20 min. at room temperature, then filter on a weighed fritted glass filter of medium porosity with suction. Extreme temperatures should be avoided; temperatures controlled at approximately 21 C. (70 F.) are preferable. Transfer the precipitate completely by means of several small quantities of the precipitating solution contained in a wash bottle, using a rubber policeman. Wash the precipitate on the filter twice with 2-ml. quantities of the same solution, then six times with small volumes of acidified (1 ml. of acetic acid in 100 ml. of alcohol) 95 per cent ethyl alcohol that has been saturated at room temperature with sodium zinc uranyl acetate. Allow the wash solution to drain through completely between washes. Finally, wash the precipitate twice with 5-ml. portions of *anhydrous* ether, added from a pipette. Continue to draw air through the filter for a minute or two after the precipitate appears dry, wipe off the crucible, set it aside near the balance for 10 to 15 min., and weigh. The empty crucible may be washed and dried in the same manner at the start and weighed as soon as it reaches room temperature. As a check on the presence of significant amounts of foreign insoluble matter in the precipitate, the crucible can be put under suction, the sodium zinc uranyl acetate dissolved in hot water, and the crucible reweighed after final washing with ether.

(*b*) *Calculation.*—Calculate the percentage of Na_2O as follows:

Na_2O, per cent = wt. of precipitate × 20.15

Determination of K_2O

31. (*a*) Evaporate the reserved 50-ml. aliquot portion (Section 25) to dryness in the 75-ml. platinum dish, and heat on the hot plate to eliminate free $HClO_4$. Perchlorates need not be destroyed, but all free $HClO_4$ should be eliminated. Cool, rinse down the inside of the dish with a little water, and add about 1 ml. of HCl and 0.5 ml. of chloroplatinic acid solution. Evaporate nearly to dryness on the steam bath so that the residue solidifies on cooling. Add about 20 ml. of ethyl alcohol (80 per cent), stir to dissolve all soluble salts, crush the residue with the flattened end of a glass rod, and filter through a fritted glass filter of medium porosity with suction. Wash the residue once or twice by decantation, transfer to the filter, and wash two or three times more on the filter with ethyl alcohol (80 per cent). Using a 100-ml. beaker as the receiver, rinse out the dish with hot water, pour it through the filter, and wash thoroughly to dissolve all potassium chloroplatinate. Add 2 ml. of HCl and a strip of magnesium ribbon to the solution, and warm while stirring until all of the platinum is reduced. The reduction with magnesium is conveniently made by wrapping the ribbon around the end of the stirring rod. Add more magnesium if necessary, and finally boil the solution for a few minutes. After settling, the solution will be color-

less if the reduction of the chloroplatinate is complete. Filter and wash the platinum several times with hot water. Ignite in a porcelain crucible in a muffle, gradually at first, and finally at 1000 C. for 5 min. Cool in a desiccator, and weigh.

(*b*) *Calculation.*—Calculate the percentage of K_2O as follows:

$$K_2O, \text{ per cent} = \text{wt. of platinum} \times 96.5$$

BORIC OXIDE

Reagents

32. (*a*) *Bromcresol Purple Indicator (0.04 per cent).*—Treat 0.10 g. of bromcresol purple with 18.5 ml. of 0.01 *N* NaOH, and dilute to 250 ml. with water. (Methyl red or *p*-nitrophenol may be used instead of bromcresol purple.)

(*b*) *Phenolphthalein Indicator (0.5 per cent).*—Dissolve 1.0 g. of the reagent in 100 ml. of 95 per cent ethyl alcohol, and dilute to 200 ml. with water.

(*c*) *Hydrochloric Acid (approximately 0.1 N).*—Prepare an approximately 0.1 *N* HCl solution free of CO_2.

(*d*) *Sodium Hydroxide (approximately 1 N).*—Prepare an approximately 1 *N* NaOH solution free of CO_2 and B_2O_3. Solutions of NaOH attack borosilicate glass. Consequently all such solutions should be freshly prepared, or stored in bottles containing no boron.

(*e*) *Sodium Hydroxide (0.05 N).*—Prepare an approximately 0.05 *N* NaOH solution free of CO_2, and standardize against the National Bureau of Standards standard sample 84*a* of acid potassium phthalate.

Procedure

33. (*a*) Intimately mix 1.000 g. of the prepared sample (Section 4) and 2.0 g. of Na_2CO_3 in a platinum crucible, and heat until a clear melt is obtained. Rotate the crucible while cooling so that the melt solidifies in a thin layer. Add 10 ml. of diluted HCl (1:1), cover, and allow to digest at room temperature with occasional stirring with a glass rod until the melt is disintegrated.

(*b*) Transfer to a 100-ml. glass-stoppered cylinder, rinse the crucible several times with small quantities of water, and dilute to 25 ml. Add 25 ml. of absolute ethyl alcohol and 50 ml. of anhydrous ether. Stopper the graduate, and mix the contents by vigorous intermittent shaking over a 5 min. period. Finally, allow the cylinder to stand for an hour or more, or until the two liquid layers have separated completely. Note and record the volumes of the two layers. Pipette out 50 ml. of the upper (ether-alcohol) layer, and transfer to a 200-ml. Erlenmeyer flask.

(*c*) Add 1 drop of bromcresol purple indicator, then add 1 *N* NaOH drop by drop, while shaking vigorously, until a permanent blue end point is reached. Add 1 ml. of 0.5 per cent phenolphthalein solution, and continue the addition of the NaOH to a pink end point. Finally, add an excess amounting to about three times the volume used between the two end points (never less than 1 ml.). Add about 50 ml. of water, and warm the solution carefully on the steam bath until the ether layer has evaporated; then transfer the flask to a hot plate and allow to boil until most of the alcohol has been eliminated. Cool, add diluted HCl (1:1) drop by drop until the solution is just acid, then add 1 *N* NaOH to faint alkalinity.[7] Treat with 0.1 *N* HCl until definitely acid (5 to 10 drops excess), warm on the steam bath, attach to a vacuum line, and allow to boil under reduced pressure for a few minutes to eliminate dissolved gases.

(*d*) Cool to room temperature, add 0.05 *N* NaOH from a burette until the

[7] With glasses containing zinc, this procedure results in its complete precipitation as the hydroxide, which may be eliminated by filtration. This step also removes all of the iron, which is likely to be troublesome if present in abnormal amounts.

color changes from yellow to blue, and record the burette reading. Add about 1 g. of mannite, and continue the titration to a permanent pink color that is not destroyed by further additions of mannite.

(*e*) *Calculation.*—The volume of NaOH solution required between the blue and the pink end points (Paragraph (*d*)) provides a measure of the boric acid contained in the aliquot portion of the ether layer. It is then possible to calculate the amount of boric acid contained in the entire ether layer, and from a knowledge of the distribution ratio, the quantity in the aqueous layer. The boric oxide content of the sample is calculated as follows:

$$B_2O_3, \text{ per cent} = V \times \left(A + \frac{B}{K}\right) \times 0.00348$$

where:

V = volume in milliliters of 0.05 N NaOH required for titration of 50 ml. of the alcohol-ether layer,

A = volume in milliliters of the alcohol-ether layer,

B = volume in milliliters of the aqueous layer, and

K = partition coefficient.

NOTE.—The value of K (partition coefficient) is taken as 0.36 for ordinary laboratory temperatures of about 25 C. If the extraction is made at a room temperature of 30 C. or higher, the value becomes 0.34.

(*f*) *Blank Titration.*—The percentage of B_2O_3 shall be corrected by a blank on the reagents. This may be done conveniently by repeating the entire procedure (Paragraphs (*a*) to (*e*)) with a glass (such as the National Bureau of Standards standard sample No. 80) known to contain no boron.

FLUORINE

Reagents

34. (*a*) *Thorium Nitrate (0.1 N).*—Dissolve 13.8 g. of $Th(NO_3)_4 \cdot 4H_2O$ in water and dilute to 1 liter. Standardize against the standard fluorine solution described in Paragraph (*b*) by titrating as described in Section 35.

(*b*) *Standard Fluorine Solution.*—Dissolve 0.442 g. of pure NaF in 1 liter of water. One milliliter of this solution will contain 0.0002 g. of fluorine. If pure NaF is not available, it may be prepared by treating pure $NaHCO_3$ with an excess of pure HF in a tubulated Gooch crucible or in a small platinum dish, evaporating the excess of HF, and heating to about 600 C. in an atmosphere of nitrogen. The NaF should be cooled in nitrogen and stored over a good desiccant.

(*c*) *Buffer Solution.*—Dissolve 9.45 g. of monochloracetic acid and 2.00 g. of NaOH in 100 ml. of water.

(*d*) *Sodium Alizarin Sulfonate Indicator.*—Prepare an aqueous 0.05 per cent solution.

Procedure

35. (*a*) Fuse 1 g. of the prepared sample (Section 4) with 4 g. of Na_2CO_3 in a platinum crucible, and allow the melt to solidify in a thin layer. Nearly fill the crucible with water, and allow to digest on the steam bath until the melt is thoroughly disintegrated. Transfer the disintegrated melt to a 250-ml. Claissen flask, rinsing the crucible several times with water. The flask should contain eight to ten glass beads to prevent bumping. Add cautiously 35 ml. of H_2SO_4 while the flask is kept cool in running water. Close the flask with a two-hole rubber stopper through which passes a thermometer and a 4-mm. glass tube extending nearly to the bottom of the flask. Connect the tube to a 2-liter Florence flask filled with water, which serves as a steam generator. Close the connection between the generator and distilling flask by means of a pinchcock.

(*b*) Connect the distilling flask to the

condenser, and distill until the temperature of the liquid reaches 135 C. In the meantime, heat the water in the Florence flask to boiling, and when a temperature of 135 C. is reached, admit steam into the Claissen flask. Adjust the rate of flow of the steam (by regulating the burners under the two flasks) so as to keep the volume and temperature of the contents of the Claissen flask about constant. Continue the distillation until about 400 ml. of distillate has collected. Add phenolphthalein and sufficient 1 *N* NaOH to the distillate to make it distinctly alkaline, and evaporate to about 100 ml.

(*c*) Cool the solution, then add 10 drops of sodium alizarin sulfonate indicator and diluted HCl (1:1). until slightly acid. Neutralize with 1 *N* NaOH, then make faintly acid with 0.1 *N* HCl. Add 1 ml. of the buffer solution and titrate with 0.1 *N* thorium nitrate to a faint, permanent pink. A blank determination should be made, using a glass that contains no fluorine (such as the National Bureau of Standards standard sample No. 128).

(*d*) *Calculation.*—Calculate the percentage of fluorine as follows:

$$\text{Fluorine, per cent} = VF \times 100$$

where:

V = volume in milliliters of thorium nitrate solution required for titration, and

F = fluorine equivalent of the thorium nitrate solution.

SULFUR TRIOXIDE

Procedure

36. (*a*) Decompose 3 g. of the prepared sample (Section 4) by treatment with $HClO_4$ and HF exactly as described in Section 25 and transfer the solution to a 600-ml. beaker. Dilute to about 200 ml., neutralize with NH_4OH, then add HCl until an excess of 2 ml. is present. Cover the beaker, heat to boiling, and add 10 ml. of $BaCl_2$ (10 per cent) drop by drop from a pipette. Continue boiling for 10 min., transfer to a steam bath, and digest for 45 min. Filter through a tight paper, transfer the precipitate completely, and wash paper and precipitate with four portions of warm water. Ignite slowly in a tared porcelain crucible until the carbon is burned, and finally heat at about 1000 C. for 10 min. Cool in a desiccator, and weigh.

(*b*) *Calculation.*—Calculate the percentage of SO_3 as follows:

$$SO_3\text{, per cent} = \text{wt. of } BaSO_4 \times 11.43$$

Standard Method of

HYDROSTATIC PRESSURE TEST ON GLASS CONTAINERS[1]

A.S.T.M. Designation: C 147 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 147; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the test procedure for determining the breaking strength of narrow-mouth glass containers when subjected to a uniform internal hydrostatic pressure. The method is intended to determine the uniformity of glass bottles and the serviceability of pressure containers.

Apparatus

2. The apparatus,[3] a suitable type of which is illustrated in Fig. 1, shall embody the following principles:

(*a*) The bottles to be tested shall be held by a split collar so designed that the bottle is not clamped but is suspended from the "bead of the finish."

(*b*) A seal shall be provided which will be watertight at the pressure to be applied.

(*c*) An automatically controlled timing mechanism shall be built into the machine so that the bottle will be under pressure for 1 ± 0.02 min.

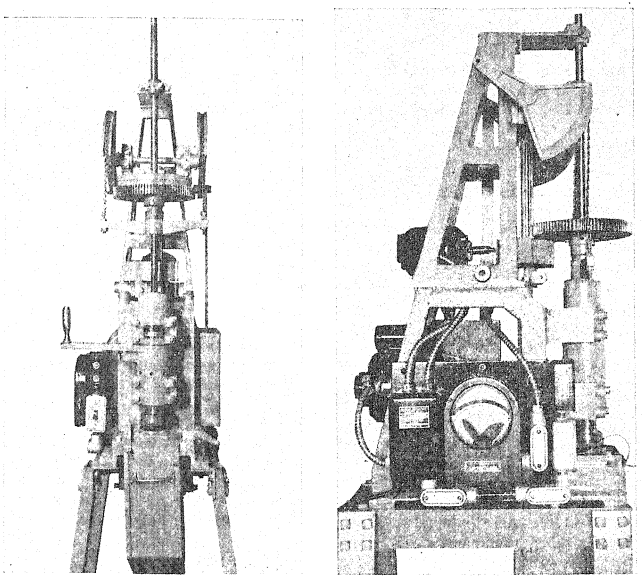
(*d*) The apparatus shall be designed so that the weight is applied directly by gravity without any intermediate cams or levers.

Sampling

3. The method of sampling a group of bottles of a given type shall be in accordance with Paragraphs (*a*) to (*c*) for the various situations described.

(*a*) *Sampling in Manufacturing Plant During Continuous Production:*

(*1*) For continuous routine checking of quality to insure that a predetermined standard of internal pressure strength is being maintained in the glassware, a sample of at least one bottle from each cavity or mold shall be taken every 3 hr. from the exit end of the annealling lehr. If the margin between the strength of



[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, this method was published as tentative from 1939 to 1943, being revised in 1940 and 1943.

[3] Six-head and single-head automatic sustained pressure testing machines developed by the Preston Laboratories meet these requirements. Detailed working drawings of the apparatus are available at a nominal cost from the American Society for Testing Materials, 260 S. Broad St., Philadelphia 2, Pa.

the glassware and the predetermined standard becomes low because of radical changes in the operations and adjustments of the machine, samples shall be taken at intervals sufficiently short to insure that all necessary information does not know which cartons will be opened by the sampler.

(*3*) For a detailed test of new mold designs or of radical changes in machine operations a sample of 10 bottles from each mold or cavity shall be required

Front View Side View

FIG. 1.—Pressure Testing Machine for Hydrostatic Test with Automatic Lift.

concerning variations in strength is be- obtained.

(*2*) For continuous routine checking of quality, including handling and packing, one bottle from each cavity or mold shall be taken every 3 hr. from cartons packed by the inspector or the packer and in such a manner that the packer for test. In case the total number of molds shall be more than 10, a total of 100 bottles distributed among the molds shall be required for the test. The bottles shall be taken from the exit end of the annealing lehr.

(*b*) *Sampling New or Unused Aged Bottles in Original Containers in Ware-*

house, Freight Car, or Truck.—A sample of at least 100 bottles shall be taken in accordance with the principles of random sampling. If the group of bottles is contained in more than 100 cartons or crates, not more than one bottle shall be taken from each container, and random sampling shall be applied to the various containers in selecting the ones to be opened. If the bottles are contained in less than 100 cartons or crates, insofar as possible, equal numbers of bottles shall be taken from each container. If the bottles are in bulk rather than in cartons or crates, the principles of random sampling shall be applied to the various parts of the several rows, layers, or tiers.

(*c*) *Sampling Stock or Group of Used or Filled Bottles in a Bottling, Packaging, or Distribution Plant, such Bottles Having Been Shuffled with Respect to Original Containers and Having Complicated and Unknown Histories.*—Whether in cartons or in racks, layers, rows, or lines, a sample of at least 100 bottles shall be taken in accordance with the principles of random sampling, and in accordance with Paragraph (*b*). If the group or stock contains bottles manufactured by more than one firm and of various vintages, the sample which is taken shall be large enough to represent proportionately all manufacturers and all vintages. Whenever possible, random samples of 100 bottles from each manufacturer and of each vintage shall be tested. Bottles bearing no manufacturer's trade-mark or other identification shall be tested separately.

Procedure

4. (*a*) The bottles shall be nearly filled with water, the permissible air space being governed by the length of plunger of the machine. The bottles shall then be placed in the split collar and the specified test pressure applied. If the bottle does not burst, this pressure will be automatically released at the end of 1 min. The test shall be continued as described in Paragraphs (*b*) to (*d*), depending on the nature of the sample.

(*b*) *Pass Test.*—The "pass test" at a specified pressure as described in Paragraph (*a*) is sufficient for the routine testing of samples from continuous production in a manufacturer's plant (see Section 3 (*a*) (*1*)).

(*c*) *Progressive Test (50 per cent Level).*—All samples obtained in accordance with Section 3 (*a*) (*2*), (*b*), and (*c*) shall be given a "progressive test" in which the test described in Paragraph (*a*) is repeated, the pressure being increased 25 psi. each time until the 50 per cent level is reached; that is, the pressure required to burst at least 50 per cent of the bottles.

(*d*) *Progressive Test (Total).*—As an alternative to the progressive 50 per cent level test described in Paragraph (*c*), the progressive test may be continued until all of the bottles break.

Report

5. The report shall include the following information, depending on the particular procedure used in the test. In all cases the detailed technique and criterion followed in taking the random sample shall be reported.

(*a*) *Pass Test in Accordance with Section 4 (b)*:

(*1*) Time of taking sample,

(*2*) Number of samples from each mold, if more than one,

(*3*) The test procedure, and

(*4*) Whether or not each bottle passed the test.

(*b*) *Progressive Test in Accordance with Section 4 (c)*:

(*1*) The initial breakage level or pressure and the number of bottles which broke at that pressure, and

(*2*) The pressure required to break 50 per cent of the bottles, interpolated from the data to the nearest 5 psi. Report this figure as the "50 per cent breakage level" or simply the "50 per cent level."

(*c*) *Progressive Test in Accordance with Section 4 (d):*

(*1*) The bursting pressures, and

(*2*) The average bursting pressure (subtract 12.5 psi. to correct for the 25 psi. loading interval).

Standard Method of

POLARISCOPIC EXAMINATION OF GLASS CONTAINERS[1]

A.S.T.M. Designation: C 148 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 148; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method for the polariscopic examination of glassware describes the procedure for determining the relative annealing stress in glass containers by comparison with reference standards. The method is intended to determine whether the annealing of the glass is commercially satisfactory.

NOTE.—The method is not intended to evaluate the cordiness or cord stresses due to composition inhomogeneities. The ring section examination[3], which is frequently used as a special means for investigating glass quality, is not yet included in this method.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Polariscope.*—A polariscope conforming to the following requirements: High brightness of field—at least 90 foot lamberts at the point where the glassware is held for examination and at least 50 foot lamberts at the edge of the field as observed with the polarizing element and protective element in operating position. The degree of polarization of the field at all points shall be not less than 99.0 per cent. The field shall be of sufficient size to permit the examination of glass containers 25 cm. (10 in.) in height at one viewing. A sensitive tint plate standardized to retard approximately a full wave length of light of 565 mμ shall be used.

(*b*) *Reference Standards.*—A set of standard disks of known internal stress.

NOTE.—Recently the Glass Container Association has prepared such a set of standard disks.[4] These disks or others prepared with at least the same degree of precision should be used for the comparison. These reference standards consist of a set of five disks, individually checked for path difference, so mounted that they can be combined additively and their total effect observed in comparison with that of a container. The optical path difference in each case is 22.8 mμ at points ¼ in. from edge. The methods of standardizing and value of errors have been completely described by Mr. T. D. Green in the private communications of the Glass Container Association.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, this method was published as tentative from 1939 to 1943, being revised in 1940 and 1943.

[3] V. C. Swicker, "The Ring-Section Examination of Glass Containers," *Bulletin* Am. Ceramic Soc., Vol. 18, No. 4, pp. 143 to 147 (1939).

[4] The standard disks are obtainable from the Hartford-Empire Co., Hartford, Conn.

Sampling

3. The method of sampling shall be in accordance with Paragraphs (*a*) to (*c*) for the various situations described.

(*a*) *Sampling in Manufacturing Plant During Continuous Production.*—For continuous routine checking of quality to insure that a predetermined standard of temper is being maintained in the glassware, a sample of glassware shall be taken across the lehr at least once every 3 hr., such sample being large enough to represent any possible differences in the annealing treatment across the lehr and large enough to represent the various types of bottles simultaneously in the lehr. Usually 6 bottles will suffice. If the margin between the temper and the predetermining standard becomes low because of radical changes in operation, samples shall be taken at intervals sufficiently short to insure that all necessary information concerning variations in temper is being obtained.

(*b*) *Sampling New or Unused Aged Bottles in Original Containers in Warehouse, Freight Car, or Truck.*—A sample of at least 100 bottles shall be taken in accordance with the principles of random sampling. If the group of bottles is contained in more than 100 cartons or crates, not more than one bottle shall be taken from each container, and random sampling shall be applied to the various containers in selecting the ones to be opened. If the bottles are contained in less than 100 cartons or crates, insofar as possible, equal numbers of bottles shall be taken from each container. If the bottles are in bulk rather than in cartons, or crates, the principles of random sampling shall be applied to the various parts of the several rows, layers, or tiers.

(*c*) *Sampling Stock or Group of Used or Filled Bottles in a Bottling, Packaging, or Distribution Plant, Such Bottles Having Been Shuffled with Respect to Original Cartons and Having Complicated and Unknown Histories.*—Whether in cartons or in racks, layers, rows, or lines, a sample of at least 100 bottles shall be taken in accordance with the principles of random sampling, and in accordance with Paragraph (*b*). If the group or stock contains bottles manufactured by more than one firm and of various vintages, the sample which is taken shall be large enough to represent proportionately all manufacturers and all vintages. Whenever possible, random samples of 100 bottles from each manufacturer and of each vintage shall be tested. Bottles bearing no manufacturer's trade-mark or other identification shall be tested separately.

Procedure

4. (*a*) *Examination of Base of Cylindrical Bottles.*—In determining the grade of annealing or the temper of the base of an ordinary cylindrical flint bottle, the bottle shall be viewed through the base. The maximum broad color pattern (Note) in the base of the bottle shall be compared with the maximum color in various numbers of the standard disks by using the disks in numeric sequence ("stacked" one on top of the other) to determine whether the maximum amount of color in the bottle base is less than that in one disk, less than that in two and greater than one, greater than two, etc. It is seldom possible to obtain an exact match of the color of the bottle with the reference standards. The temper of the bottle shall then be recorded in accordance with the following rules:

Rule.—When the color of a bottle is greater than that of N disks but less than $N + 1$ disks, the temper is $N + 1$; that is, corresponding numerically to the larger number of disks, as follows:

Temper 1.....less than 1 disk
Temper 2.....less than 2, greater than 1 disks
Temper 3.....less than 3, greater than 2 disks
Temper 4.....less than 4, greater than 3 disks
Temper 5.....less than 5, greater than 4 disks
Temper 6.....greater than 5 disks

NOTE.—The color observed by the procedure described in Paragraphs (*a*), (*b*), and (*c*) should be the broad color patterns produced by annealing stresses, and this temper is considered the "lehr temper." Local stresses clearly due to cords or composition inhomogeneities should be distinguished from the broad pattern and ignored in the assignment of the temper grading.

(*b*) *Examination of Square, Oval, and Irregular Shapes.*—In determining the temper of square or oval and other irregular shapes, the polariscopic examination shall be made at the curve or corner that shows the most color and the temper shall be recorded in accordance with the rule given in Paragraph (*a*).

(*c*) *Examination of Sidewalls.*—In determining the temper of the sidewalls of any bottle, the maximum color of any part of the sidewall shall be matched with the maximum color in any part of the disks, and the temper shall be recorded in accordance with the rule given in Paragraph (*a*).

Report

5. The report shall include a record of the temper gradings, and information concerning observed areas of localized strain arising from a cordy condition of the glass.

Standard Method of

THERMAL SHOCK TEST ON GLASS CONTAINERS[1]

A.S.T.M. Designation: C 149 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 149; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test for determining the relative resistance of commercial glass containers (bottles and jars) to thermal shock is intended to apply to all types of glass containers which are required to withstand temperature changes (thermal shock) in service such as in washing, pasteurization, or "hot pack" processes, or in being transferred from a warm to a colder medium or *vice versa*.

NOTE.—It is recommended that glassware subjected to this thermal shock test be not later subjected to the hydrostatic pressure test, because lower pressure strengths will be obtained.

Apparatus

2. (*a*) The apparatus[3] consists essentially of a basket for holding the glassware and two tanks, one containing hot water and one containing cold water. An automatic mechanism for immersing and transferring the basket of bottles from the hot to the cold bath shall be provided and shall be so geared that exactly 15 sec. will be consumed in the transfer. A suitable type of apparatus is illustrated in Fig. 1.

(*b*) A device shall be provided to maintain the temperature of the baths within plus or minus 1 F. of the specified temperatures. Indicating controllers which operate solenoid valves to admit hot water to the hot tank or cold water to the cold tank are recommended. Otherwise, a dial thermometer should be attached and the valves operated manually.

Sampling

3. The method of sampling a group of bottles of a given type shall be in accordance with Paragraphs (*a*) to (*c*) for the various situations described.

(*a*) *Sampling in Manufacturing Plant During Continuous Production:*

(*1*) For continuous routine checking of quality to insure that a predetermined standard of internal pressure strength

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, this method was published as tentative from 1939 to 1943, being revised in 1940 and 1943.

[3] Detailed drawings of satisfactory apparatus for this test are available at a nominal cost from the American Society for Testing Materials, 260 S. Broad St., Philadelphia 2, Pa.

is being maintained in the glassware, a sample of at least one bottle from each cavity or mold shall be taken every 3 hr. from the exit end of the annealing lehr. If the margin between the strength of the glassware and the predetermined standard becomes low because of radical changes in the operations and adjustments of the machines, samples shall be taken at intervals sufficiently short to insure that all necessary information concerning variations in strength is being obtained.

(2) For continuous routine checking of quality, including handling and packing, one bottle from each cavity or mold shall be taken every 3 hr. from cartons packed by the inspector or the packer and in such a manner that the packer does not know which cartons will be opened by the sampler.

(3) For a detailed test of new mold designs or of radical changes in machine operations a sample of 10 bottles from each mold or cavity shall be required for test. In case the total number of molds shall be more than 10, a total of 100 bottles distributed among the molds shall be required for the test. The bottles shall be taken from the exit end of the annealing lehr.

(*b*) *Sampling New or Unused Aged Bottles in Original Containers in Warehouse, Freight Car, or Truck.*—A sample of at least 100 bottles shall be taken in accordance with the principles of random sampling. If the group of bottles is contained in more than 100 cartons or crates, not more than one bottle shall be taken from each container, and random sampling shall be applied to the various containers in selecting the ones to be opened. If the bottles are contained in less than 100 cartons or crates, insofar as possible, equal numbers of bottles shall be taken from each container. If the bottles are in bulk rather than in cartons, or crates, the principles of random sampling shall be applied to the various parts of the several rows, layers, or tiers.

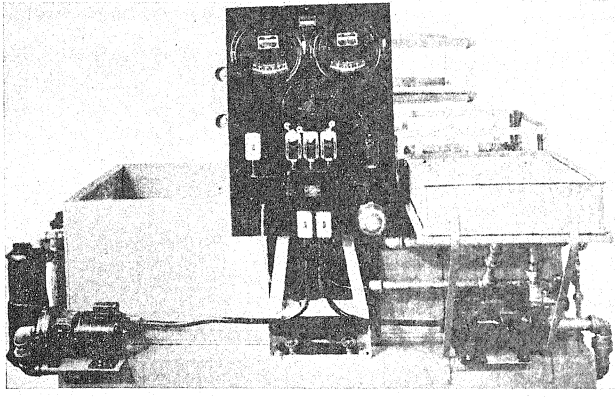


FIG. 1.—Automatic Thermal Shock Testing Machine.

(*c*) *Sampling Stock or Group of Used or Filled Bottles in a Bottling, Packaging, or Distribution Plant, Such Bottles Having Been Shuffled with Respect to Original Containers and Having Complicated and Unknown Histories.*—Whether in cartons or in racks, layers, rows, or lines, a sample of at least 100 bottles shall be taken in accordance with the principles of random sampling, and in accordance with Paragraph (*b*). If the group or stock contains bottles manufactured by more than one firm and of various vintages, the sample which is taken shall be large enough to represent proportionately all manufacturers and all vintages. Whenever possible, random samples of 100 bottles from each manufacturer and of each vintage shall be tested. Bottles bearing no manufacturer's trade-mark or other identification shall be tested separately.

Procedure

4. (*a*) The temperature of the baths shall be adjusted so that the cold bath is at 70 F. and the hot bath is at a temperature hotter than the cold bath by the specified increment (in most cases this increment will be 75 F. for the first immersion). When the temperatures of the baths are within plus or minus 1 F. of those specified, the baskets shall be filled with bottles and immersed in the hot bath, allowed to soak for 5 min., then transferred to the cold bath and immersed for 30 sec., and then removed from the bath. The 5-min. immersion in the hot bath shall be controlled within 3 sec. and the time required for transfer from the hot to the cold bath shall be 15 ± 0.33 sec. During the test the apparatus shall be protected from drafts in a sheltered laboratory. The test shall then be continued according to one of the alternatives in Paragraph (*b*) and (*c*), depending on the nature of the sample.

(*b*) *Pass Test.*—The "pass test" at a specified increment or temperature differential as described in Paragraph (*a*) is sufficient for the routine testing of samples from continuous production in a manufacturer's plant (see Section 3 (*a*) (*1*)).

(*c*) *Progressive Test (50 per cent Level).*—All samples obtained in accordance with Section 3 (*a*) (*2*), (*b*), and (*c*) shall be given a "progressive test" in which the test described in Paragraph (*a*) is repeated, the temperature differential being increased 5 F. each time by increasing the temperature of the hot water, until at least 50 per cent of the bottles are broken.

NOTE.—Bottles which have not broken in the test should not be used for further testing.

Report

5. The report shall include the following information, depending on the particular procedure used in the test. In all cases the detailed technique and criterion followed in taking the random sample shall be reported.

(*a*) *Pass Test in Accordance with Section 4 (b):*

(*1*) Time of taking sample,

(*2*) Number of samples taken from each mold, if more than one,

(*3*) The temperature differential employed in the test, and

(*4*) Whether or not each bottle passed the test.

(*b*) *Progressive Test in Accordance with Section 4 (c):*

(*1*) The initial breakage level and the number broken, and

(*2*) The thermal shock differential required to break 50 per cent of the bottles, interpolated to the nearest 1 F. This figure is the "50 per cent breakage level" or simply the "50 per cent level."

Standard Method of

FLEXURE TESTING OF GLASS[1]

DETERMINATION OF MODULUS OF RUPTURE

A.S.T.M. Designation: C 158 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 158; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the modulus of rupture of glass, that is, the stress in flexure which a specimen of the glass develops at rupture. In practice the modulus of rupture is usually taken as the stress at which the specimen breaks in the flexure test.

Apparatus

2. (*a*) *Testing Machine.*—The loading device shall be sufficiently adjustable to give a uniform rate of increase of stress in the specimen of 10,000 ± 1,000 psi. per min. (7.0 ± 0.7 kg. per sq. mm. per min.). The apparatus shall be suitably insulated from any external vibration.

(*b*) *Bearing Edges.*—For the support of the test specimen a set of two knife-edge bearing surfaces approximately $\frac{1}{16}$ in. in radius and made of brass or mild steel shall be provided. The supports shall be spaced 8 in. between centers. The load shall be applied through a third knife-edge bearing located centrally between the supports and mounted in such a manner that the applied load acts always in a vertical line. For the testing of flat specimens, the central bearing and one of the outer bearings shall be pivoted laterally to compensate for minor irregularities of the test specimen.

Test Specimens of Rods

3. (*a*) *Preparation of Specimens.*—Information concerning the method of manufacture of the glass and the rods shall be supplied with the samples. Any special treatment given the material shall be indicated. At least 30 specimens shall be used for one test (Note). Test specimens shall be at least 10 in. in length and $\frac{3}{8} \pm \frac{1}{32}$ in. in diameter. Although most rods are of elliptical section, the maximum and minimum diameters of the specimen shall not differ by more than 0.020 in., nor shall either diameter vary by more than 0.005 in. in 10 in. The specimens shall be straight within $\frac{1}{8}$ in. in 10 in., and the curve, if present, shall be in one plane only.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-14 on Glass and Glass Products.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1943, being revised in 1943.

(*b*) *Examination of Specimens.*—After careful inspection, test specimens containing any obvious defect shall be discarded. At least ten of the specimens shall be examined for strain. If any of these is not within the requirements prescribed in the Appendix, the remainder of the specimens shall be examined and those exceeding the strain test limit shall be rejected.

NOTE.—In view of the large variation encountered in measurements of the modulus of rupture, not only a large number but a wide range of samples is essential. For example, in the case of rods the specimens should be cut from a number of different lengths of cane; specimens of flat glass should be taken from several sheets, or at least from several regions of a single sheet. Otherwise, the results may be representative of only a small sample.

Test Specimens of Flat Glass

4. (*a*) *Preparation of Specimens.*—Test specimens of flat glass shall be cut from sheet stock with a diamond or a steel wheel. Both longitudinal cuts shall be on the same original surface, and none of the original edge of the sheet shall be used as the longitudinal side of a specimen. The end cuts may be made on either surface. The direction of cutting approximately half the total number of specimens shall be perpendicular to the direction of cutting the remainder. At least 30 specimens shall be used for one test (Note, Section 3). Specimens shall be approximately 10 in. in length and $1\frac{1}{2} \pm \frac{1}{32}$ in. in width. Specimens of plate glass shall be $\frac{1}{4} \pm 0.030$ in. in thickness. Drawn glass shall be designated in commercial or calipered thickness within plus or minus 0.010 in. The thickness of any specimen shall not vary by more than plus or minus 0.005 in.

(*b*) *Examination of Specimens.*—Any specimen may be rejected for defects considered likely to cause undue weakness. Specimens showing surface scratches, poor cutting or splinters, reentrant angles or irregularities on the side opposite the cutter mark shall be rejected. Annealing shall be such that the stress at the center, viewed edgewise, does not exceed 200 psi. (Appendix).

Procedure

5. Specimens having cut edges shall be broken with the cutter marks on the side under compression. The permissible initial load shall not exceed that corresponding to a stress of approximately 4000 psi. The specimen shall be bent until fractured under a constant loading rate such that the rate of increase of stress is 10,000 ± 1,000 psi. per min.

NOTE.—No specimen may be rejected during test because of low flexural strength.

Calculation and Report

6. (*a*) *Calculation.*—The initial stress, rate of increase of stress, and modulus of rupture shall be calculated as follows:

Stress due to initial load:

$$R_0 = \frac{w_0}{w} \times R$$

Rate of increase of stress:

$$S = \frac{R - R_0}{t}$$

Modulus for elliptical rod specimens:

$$R = 20.36 \frac{w}{bd^2}$$

Modulus for rectangular specimens:

$$R = 12 \frac{w}{bd^2}$$

where:

R = modulus of rupture in pounds per square inch,

R_0 = stress due to initial load in pounds per square inch,

S = rate of increase of stress in pounds per square inch,
w_o = initial load in pounds,
w = breaking load in pounds,
b = width of specimen in inches,
d = thickness of specimen in inches, and
t = time from start of continuous loading rate to rupture in minutes.

NOTE.—Metric units may be used by substitution of the proper constants.

(*b*) *Report.*—The report shall include the data itemized in Paragraph (*a*) and the maximum, minimum, and average value of the modulus of rupture for each group of similar specimens. The standard deviation of the modulus of rupture shall also be obtained in accordance with the A.S.T.M. Manual on Presentation of Data.[3]

APPENDIX

METHOD FOR MEASURING STRAIN

A1. Strains shall be measured with a calibrated wedge or Babinet compensator.

A2. The stress optical coefficient shall be determined for unknown glass, but may be taken as 1 mμ per inch of light path which is equivalent to 2.18 psi. (1 mμ per centimeter of light path, equivalent to 0.389 kg. per sq. cm.) for common soda lime window, plate, and bottle glass.

A3. Laths of glass shall not have more than 200 psi. tension at the middle nor more than 400 psi. compression at the surface. This is equivalent respectively to 90 mμ and 180 mμ per inch of light path in common glass.

A4. Specimens of rods may be examined by viewing through a diameter distant at least four diameters from the nearest end. The *apparent* tension at the center shall not exceed 133 psi. (equivalent to 61 mμ per inch of diameter for common soda lime glass). As an alternative, specimens of rods may be examined by cutting a piece from the end and measuring the stress at the circumference by viewing it axially. The stress shall not exceed 400 psi. (equivalent to 180 mμ per inch of length for common soda lime glass).

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A6-1925

Standard Specifications for

DRAIN TILE[1]

A.S.T.M. Designation: C 4 – 24

ADOPTED, 1914; REVISED, 1916, 1921, 1924.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 4; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover three classes of drain tile as follows:

Farm Drain Tile, intended for ordinary private drainage work on farms, for moderate sizes and depths,

Standard Drain Tile, intended for ordinary district land drainage at moderate depths,

Extra-Quality Drain Tile, intended for district land drainage, for considerable depths and where an extra quality is desired.

Basis of Purchase

2. The purchaser shall specify the class or classes of tile to be supplied, whether Farm Drain Tile, Standard Drain Tile, or Extra-Quality Drain Tile. Standard Drain Tile shall be supplied where no other advance selection is stated.

Basis of Acceptance

3. (*a*) The acceptability of drain tile shall be determined (1) by the results of the chemical and physical tests hereinafter specified, and (2) by visual inspection, to determine whether the tile complies with the specifications as to dimensions, shape, and freedom from visible external and internal defects.

(*b*) The acceptance of drain tile as satisfactorily meeting one of these two general requirements shall not be construed as in any way waiving the other.

MATERIALS AND MANUFACTURE

Materials

4. (*a*) These specifications shall apply to drain tile made of shale, fire clays, or surface clays and to drain tile made of concrete.

(*b*) By shale is meant a thinly stratified, consolidated, sedimentary clay[3] with well-marked cleavage parallel to the bedding.

(*c*) By fire clay is meant a sedimentary clay[3] of low flux content.

NOTE.–It is usually associated with coal measures.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-6 on Drain Tile.

[2] Editorially revised in 1939.

[3] These descriptions of the terms "surface clay," "fire clay," and "shale" are based upon the following definition for the term "clay":

Clay.—An earthy or stony mineral aggregate consisting essentially of hydrous silicates of alumina, plastic when sufficiently pulverized and wetted, rigid when dry, and vitreous when fired at a sufficiently high temperature.

(*d*) By surface clay is meant an unconsolidated, unstratified clay,[3] occurring on the surface.

(*e*) By concrete is meant a suitable mixture of portland cement, mineral aggregates, and water, hardened by hydraulic chemical reaction.

(*f*) If the purchaser desires to exclude any of these materials he shall so specify in advance. All materials used shall be first-class of their kind and suitable for the purpose.

Manufacture

5. The method of manufacture shall be such as to insure excellence of product and uniformity in quality.

CHEMICAL TESTS AND REQUIREMENTS

Chemical Tests and Requirements

6. (*a*) The purchaser may specify special chemical requirements as to resistance of the tile to chemical action in cases where soils or drainage waters have marked acid or alkaline character, or are of abnormally high temperature, and may prescribe chemical tests of the tile to ascertain whether these special requirements are met. Without a special agreement in advance, no drain tile shall be rejected by reason of its composition as determined by ultimate chemical analysis.

(*b*) The presence in drain tile of visible grains or masses of caustic lime, iron pyrites, or any other minerals which are known to cause slaking or disintegration of the tile, shall be construed as a valid ground for rejection, unless satisfactory proof be submitted that the tile is permanent and durable, and that the objectionable minerals are not present in quantity or condition to work damage.

PHYSICAL TESTS

Physical Tests

7. The physical tests of drain tile shall include strength tests and absorption tests, and may also include freezing and thawing tests when specified by the purchaser in advance or when called for by the manufacturer or other seller as provided in Sections 34, 35, 47, and 52.

Selection of Specimens

8. The specimens of tile shall all be selected at the factory or at the shipping destination, or at the trench, at the option of the purchaser. The selection shall be made by a competent inspector employed by the purchaser. The inspector shall divide the tile into subclasses if lack of uniformity in any important particular warrants such division, and shall select enough representative specimens of tile from each sub-class for a complete set of standard physical tests.

Number and Cost of Specimens

9. A standard physical test shall comprise tests of five individual tiles. Specimens of tile may be selected by the inspector in such number as he judges necessary to determine fairly the quality of all the tile. The manufacturer or other seller shall furnish specimens of tile without separate charge up to 0.5 per cent of the whole number of tile, and the purchaser shall pay for all in excess of that percentage at the same rate as for other tile.

Strength Tests

Test Specimens

10. The specimens of tile for the strength test shall be unbroken, full-size tile.

Moisture Condition of Specimens

11. The walls of the tile shall be, at the time of testing, as thoroughly wet as will result from completely covering with hay, cloth, or similar absorbent material, and keeping the covering wet for not less than 12 hr.

Temperature Condition of Specimens

12. No specimen of tile shall be exposed to water or air temperatures lower than 40 F. from the beginning of wetting until tested. Frozen tile shall be completely thawed before the wetting begins.

Weighing

13. Each specimen shall be weighed on reliable scales just prior to testing, and the weights shall be reported.

Application of Load

14. Any machine or hand method which will apply the load continuously, or in increments not exceeding 5 per cent of the estimated total breaking load, may be used in making the test. The tile shall not be allowed to stand under load longer than is required for observing and recording the loads. All solid parts of the bearing frames and bearing blocks shall be so rigid that the distribution of the load will not be affected appreciably by the deformation of any part. All bearings and the specimens of tile shall be so accurately centered as to secure a symmetrical distribution of the loading on each side of the center of the tile in every direction.

Choice of Method

15. The purchaser shall choose (1) sand bearing method, (2) two-edge-bearing method, or (3) three-edge-bearing method, for use in making strength tests of drain tile (see Sections 18, 19, and 20).

Calculations and Report

16. The test results shall be calculated and reported, in pounds per linear foot of tile, in terms of the "ordinary supporting strength."[4]

The ordinary supporting strength shall be calculated by multiplying the test breaking loads by the following factors: For sand bearings, 1.00; for two-edge bearings, 1.50; for three-edge bearings, 1.50.

The results of the strength tests shall be reported separately for each of the five individual specimens of tile constituting a standard test, together with the average.

Modulus of Rupture

17. The modulus of rupture may or may not be calculated and reported, at the option of the purchaser. When reported it shall be calculated as follows:[5]

$$M = 0.20\, r \frac{W}{12} \quad \ldots\ldots\ldots (1)$$

$$f = \frac{6M}{t^2} \quad \ldots\ldots\ldots\ldots (2)$$

where:

M = maximum bending moment in wall in pound-inches per inch of length,
r = radius of middle line of tile wall in inches,
W = ordinary supporting strength, calculated as prescribed in Section 16, in pounds per linear foot of tile,
f = modulus of rupture in pounds per square inch, and
t = thickness of tile wall in inches.

---

[4] The "ordinary supporting strength," when calculated as specified in Section 16, is approximately equal to the actual supporting strength of a tile when laid in a ditch by the "ordinary" method. See Note under Table II.

[5] The coefficient of 0.20 in Eq. 1 approximates the value found by theoretical analysis and also that determined by extended tests.

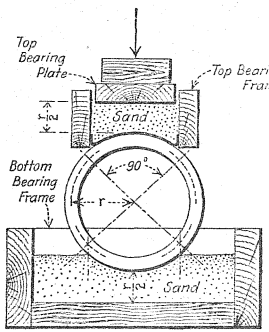

FIG. 1.—Sand Bearings.

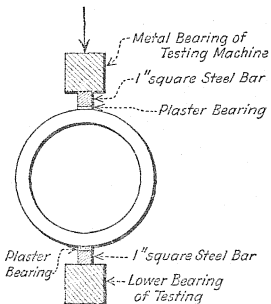

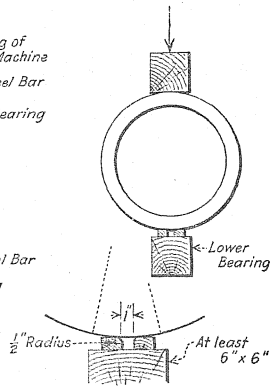

FIG. 2.—Two-Edge Bearings.

Detail of Lower Bearing.

FIG. 3.—Three-Edge Bearings.

Five-eighths of the weight of the tile per linear foot for sand bearings, or three-fourths for two-edge or three-edge bearings, shall be added to W in calculating the maximum bending moment M, when such addition exceeds 5 per cent of W. The value of t used shall be the average thickness of the wall at the top of the tile or that at the bottom, selecting the lesser of the two.

Sand Bearing Method

18. (*a*) When the sand-bearing method is used (see Fig. 1), the ends of each specimen of tile shall be accurately marked in quarters of the circumference prior to the test. Specimens shall be carefully bedded in sand, above and below, for one-fourth the circumference of the tile measured on the middle line of the wall. The depth of bedding above and below the tile at the thinnest points shall be one-half the radius of the middle line of the wall.

(*b*) The sand used shall be clean, and shall be such as will pass a 4760-micron (No. 4) sieve.

(*c*) The top bearing frame shall not be allowed to come in contact with the tile nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck level with a straightedge, and shall be covered with a rigid top-bearing plate, the lower surface of which is a true plane, made of heavy timbers or other rigid material, capable of distributing the test load uniformly without appreciable bending. The test load shall be applied at the exact center of this top bearing plate, in such a manner as to permit free motion of the plate in all directions. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used. The test may be made without the use of a testing machine by piling weights directly on a platform resting on the top bearing plate, provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the tile, and that the platform shall not be allowed to touch the top bearing frame.

(*d*) The frames of the top and bottom bearings shall be made of timbers so heavy as to avoid appreciable bending by the side pressure of the sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the tile during the test. A strip of cloth may be attached, if desired, to the inside of the upper frame on each side along the lower edge, to prevent the escape of sand between the frame and the tile.

Two-Edge-Bearing Method

19. (*a*) When the two-edge-bearing method is used (see Fig. 2) the ends of each specimen of tile shall be accurately marked in halves of the circumference prior to the test.

(*b*) The tile to be tested shall be supported by a metallic knife bearing 1 in. wide and extending the length of the tile. Before the tile is placed, a fillet of plaster of Paris and sand 1 in. wide, and thick enough to compensate for all the inequalities of the tile barrel, shall be cast on the surface of the knife-edge bearing. The tile shall be placed upon the fillet while the plaster of Paris is still somewhat plastic. The load shall be applied through an upper knife bearing of the same size and length as the lower bearing. A plaster of Paris fillet 1 in. wide shall be cast along the length of the crown of the tile to equalize the lower bearing before the upper one is brought into contact.

(*c*) Both of the bearings shall be sufficiently rigid to transmit and receive uniform loads throughout their lengths without deflection, and shall be so attached to the machine as to transmit

and receive the maximum stresses produced by the test without lost motion, vibration, or sudden shock.

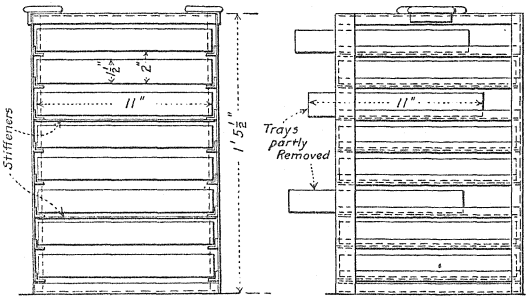
Three-Edge-Bearing Method

20. When the three-edge-bearing method is used (see Fig. 3), the ends of each specimen of tile shall be accurately marked in halves of the circumference prior to the test. The lower bearings shall consist of two wooden strips with vertical sides, having their interior top corners rounded to a radius of approximately $\frac{1}{2}$ in. The strips shall be straight, and shall be securely fastened to a rigid block with their interior vertical sides 1 in. apart. The upper bearing shall be a wooden block, straight and true from end to end. The test load shall be applied through the upper bearing block in such a way as to leave the bearing free to move in a vertical plane passing midway between the lower bearings. In testing a tile which is "out of straight," the lines of the bearings chosen shall be from those which appear to give most favorable conditions for fair bearings.

Absorption Test

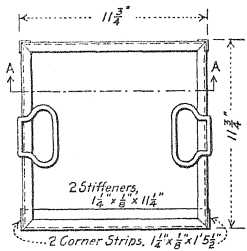
Test Specimens

21. Not less than three separate test specimens from each of five separate tiles shall be taken as a "standard sample" for the absorption test. Of the three specimens from each tile, one shall be taken from one end, another from the opposite end, and the third shall be taken from the middle portion of the tile. Each specimen shall be of from 12 to 20 sq. in. in area, measured upon the exterior or convex side, and shall be as nearly square as the nature of the material will readily permit. The specimens shall be obtained by breaking the tile, and shall be apparently sound, solid pieces of the wall of the tile, and shall not show cracks or fissures or shattered edges due to the shock of breaking or cutting. The specimens may be obtained from the broken pieces of the tiles used in the strength test, if the restrictions as to the size and location of the specimens can be duly observed. The specimens shall be so marked as to permit the identity of each one to be ascertained at any stage of the test.



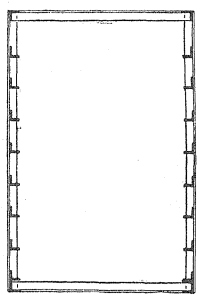
Drying Test Specimens

22. Preparatory to the absorption test, all specimens shall be first weighed and then dried in a drier or oven, at a temperature of not less than 110 C. (230 F.) for not less than 3 hr. After removal from the drier, the specimens shall be allowed to cool to a temperature of 20 to 25 C. (68 to 77 F.) and reweighed. If the specimens were apparently dry when taken, and the second weight closely checks the first, the specimens shall be considered dry. If the specimens were known to be wet when taken, they shall be placed in the drier for a further drying treatment of 2 hr, and reweighed. If the third weight checks the second, the specimens shall be considered dry. In case of any doubt, the specimens must be redried for 2-hr. periods until check weights are obtained.



Weighing and Reweighing

23. The balance used shall be sensitive to 0.5 g. when loaded with 1 kg., and weighings shall be read at least to the nearest gram. Where other than metric weights are used, the same order of accuracy must be obtained.



In reweighing after immersion, the specimens shall be removed from the water, allowed to drain for not more than 1 min., the superficial water removed by towel or blotting paper, and the specimens at once put upon the balance.

Front Elevation. Side Elevation.

defects, or other suitable timber 1 by 6 in., unless otherwise specified.

Box, Using Salt and Ice for Freezing.

Immersion of Test Specimens

24. Specimens after weighing shall be placed in a suitable woven-wire receptacle, packed tightly enough to prevent jostling, covered with distilled water or rain water, raised to the boiling point and boiled for 5 hr., and then cooled in water to a final temperature of 10 to 15 C. (50 to 59 F.).

Calculations and Report

25. The test results shall be calculated as percentages of the initial dry weight, carried to the nearest first decimal place. The results shall be reported separately for each individual specimen, together with the mean of the fifteen or more specimens comprising the standard sample, the maximum and the minimum single observations entering into the mean, and the variation between the maximum and the minimum of the three specimens of each tile represented in the standard sample.

Freezing-and-Thawing Tests

Test Specimens

26. The test specimens employed in making the freezing-and-thawing test shall be another set selected as specified in Section 21 for the absorption test.

Drying Test Specimens

27. The specimens shall be dried as specified in Section 22.

Weighing and Reweighing

28. The same scales and weights as are specified in Section 23 for the absorption test or others of equivalent sensitivity and accuracy shall be employed for the weighings required in the freezing-and-thawing test. The same procedure in weighings and reweighing as specified in Section 23 shall be followed.

Immersion of Test Specimens

29. The specimens shall be immersed for 72 hr. in water having a temperature of 18 to 24 C. (65 to 75 F.) and then weighed as specified in Section 23.

Freezing and Thawing

30. When the specimens have been weighed after saturation with water, they shall be returned to the water and kept immersed until the freezing test is begun. For freezing, they shall be placed with their concave faces upward in watertight metal trays, suitably mounted in a rigid metal crate,[6] and immersed in ice water until the specimens have attained substantially the temperature of the water, after which the water shall be drawn down to a depth of $\frac{1}{2}$ in. in each tray. The crate shall then be lifted as a whole, without disturbing the specimens, and placed in the freezing apparatus.

Freezing shall be performed in a quiet atmosphere, free from perceptible natural or artificial currents. If artificial freezing apparatus is employed,[7] the apparatus shall have sufficient heat-absorbent capacity to enable the temperature of the freezing chamber to be brought to −10 C. (+14 F.) or below, within 30 min. after the introduction of the specimens. The temperature in the freezing apparatus shall not fall lower than − 20 C. (−4 F.). The freezing shall be continued until the water in the trays is frozen solid. Exposure to freezing conditions in excess of this requirement shall be considered as without significance.

At the conclusion of freezing under the specified conditions, the crate of

---

[6] Fig. 4 shows a crate and trays suitable for use in the box for artificial freezing illustrated in Fig. 5.

[7] Artificial freezing will generally be necessary. It may be conducted in a commercial zero (Fahrenheit) refrigerating room, or in an artificial freezing box similar to the one shown in Fig. 5 in which zero temperature (Fahrenheit scale) can readily be produced by the use of salt and ice.

specimens shall be withdrawn and at once immersed in water at a temperature of 18 to 24 C. (65 to 75 F.) in a special receptacle of proper size. Heating shall be continued so that the water will regain the required temperature as soon as practicable after the specimens are immersed. A temperature of 18 to 24 C. (65 to 75 F.) shall then be maintained for not less than 2 hr. At the conclusion of the thawing treatment, the crate of specimens shall be inspected and the condition of each sample after each thawing shall be noted in the records.

Method of Determining Failure

31. Failure under the freezing-and-thawing treatment shall be considered to be reached when:

(*a*) The specimens show superficial disintegration or spalling with loss of weight of more than 5 per cent of the initial dry weight; or,

(*b*) The specimens are badly cracked in other than lamination planes; or,

(*c*) The specimens show evident serious loss of structural strength.

TABLE I.—PHYSICAL TEST REQUIREMENTS FOR DIFFERENT CLASSES OF DRAIN TILE.

CAUTION.—Drain tile meeting these requirements are not necessarily safe against cracking in ditches. For safe requirements as against cracking, see Table II.

42[a]	(Not Permitted)	(Not Permitted)	(Not Permitted)	(Not Permitted)	2600	9	13	10	4200	7	11	9

[a] Larger sizes recommended as standard are as follows: 45, 48, 54, and 60 in.

NOTE.—When the freezing-and-thawing test is made as provided in Section 7, the number of freezings and thawings to be endured shall be as follows: For farm drain tile, 24; for standard drain tile, 36; for extra-quality drain tile, 48.

PHYSICAL TEST REQUIREMENTS

Physical Test Requirements

32. The different classes of drain tile shall conform to the physical test requirements prescribed in Table I.

Absorption of Tile Made of Mixed Clays

33. Drain tile made of mixtures of surface clays with other clays shall conform to the absorption requirements for surface-clay tile in Table I when the proportion of surface clay is 75 per cent or more and to the requirements for

TABLE II.—STANDARD ORDINARY SUPPORTING STRENGTHS OF DRAIN TILE FOR ORDINARY SAND AND FOR THOROUGHLY WET CLAY DITCH FILLING MATERIALS.

NOTE.—Ordinary Pipe Laying is pipe laying in accordance with customary good practice in tile-drain construction whereby the underside of the pipe is well bedded on soil for 60 to 90 deg. of the circumference.

First-Class Pipe Laying is pipe laying in accordance with the best customary practice in pipe-sewer construction, whereby the entire underside of the pipe is very thoroughly bedded on soil and the entire pipe is surrounded by well-compacted soil, under the direction of an inspector constantly present on the work.

When pipe is laid in a Concrete or Other Permanent Masonry Cradle, strong enough to carry the entire load to the sub-base without breaking and large enough to prevent material settlement, the standard strengths for all dimensions of ditches and all filling materials shall be those specified for Standard Drain Tile in Table I.

shale and fireclay tile for all other proportions.

Appeal from Absorption

34. In the event that a standard sample (Section 21) of tile fails to meet the requirements of the absorption test, the manufacturer or other seller may demand recourse to the freezing-and-thawing test, to be made at his expense. In such recourse, the number of tiles tested shall be four times the number represented by the standard sample (Section 21). If the material passes the freezing-and-thawing test satisfactorily, it shall not be rejected on account of its failure to meet the absorption requirements specified in Table I, but the average percentage of absorption of the specimens used in the freezing-and-thawing test shall be adopted as the maximum allowable mean absorption for the contract in question.

Limits of Fluctuation of Individual Test Specimens in Physical Tests

35. (*a*) In the strength tests, individual tiles of a standard test whose mean strength is satisfactory may fall 25 per cent below the requirement for the average without causing rejection. In the absorption test, the absorption of individual tiles of a standard sample (Section 21) which gives a satisfactory mean absorption percentage, may exceed the average by 25 per cent without causing rejection. In the freezing-and-thawing test, at least 95 per cent of all the tiles tested shall meet the requirement.

(*b*) In the event of the failure of a standard sample (Sections 9, 21, and 26) to meet the above requirements, the manufacturer or other seller may thoroughly cull the material and submit a portion for retest at his own expense, and for such retest the number of tiles per sample shall be 10 for the strength and absorption tests and 20 for the freezing-and-thawing test. In the event of the failure of the material after culling to pass the requirements, it shall be rejected without further test.

NOTE.–When the freezing-and-thawing test is made as provided in Section 7, the number of freezings and thawings to be endured shall be as follows: For farm drain tile, 24; for standard drain tile, 36; for extra-quality drain tile, 48.

Strength when Manufacturer is held Responsible for Cracking in Ditches

36. The manufacturer or other seller shall not be held responsible for cracking of drain tile in ditches unless by special agreement in advance, and in any event his obligation shall be held to be discharged by the delivery of drain tile having the minimum ordinary supporting strengths specified in Table II; and, if it is not otherwise specified in advance by the purchaser, tile shall be supplied of the strengths specified for clay ditch filling, for "ordinary" pipe laying, and for widths of ditch at the level of the top of the tile equal to 0.5 ft. greater than the outside diameters of the tile. The purchaser shall furnish to the manufacturer or other seller complete information, in advance of receiving bids, as to the number of linear feet of drain tile of each diameter required for each different depth of ditch, measured to the nearest foot from the surface of the ground to the top of the tile.

VISUAL INSPECTION

Visual Inspection

37. All drain tile shall be given a thorough visual inspection at the trench by a competent inspector employed by the purchaser. The purposes of the visual inspection shall be: (1) to cull and reject imperfect individual tiles, and (2) to determine whether the tiles, independently of meeting the chemical and the physical test requirements,

comply with the specifications of general properties, especially as stated hereinafter.

Shape

38. All drain tile shall be of approximately circular cross-section, except when otherwise specified in advance. They shall be approximately straight, except in the case of special connections. The ends shall be so regular and smooth as readily to admit of making close joints by turning and pressing together adjoining tile.

Nominal Sizes

39. The sizes of drain tile shall be designated by their interior diameters.

Minimum Lengths

40. Drain tile smaller than 12 in. in diameter shall have a minimum length of 12 in. Tile of from 12 to 30 in. in diameter, inclusive, shall have lengths not less than the diameters. Tile larger than 30 in. in diameter shall have a minimum length of 30 in.

Structure

41. Drain tile shall be substantially uniform in structure throughout, and the inspector shall investigate this property by examining fractured surfaces.

Ring

42. Drain tile shall give a clear ring when stood on end and while dry tapped with a light hammer.

Color

43. The inspector may use the color of drain tile as a general guide in sorting and inspecting, but he shall first so familiarize himself with the raw materials and the processes used in the manufacture of the particular tile in question as to be competent to interpret the true meaning of variations in their color.

Inside Smoothness

44. Drain tile shall be reasonably smooth on the inside.

Cracks, Checks, Chips, and Broken Pieces

45. Drain tile shall be free from cracks and checks extending into the body of the tile in such a manner as to decrease the strength appreciably. Tile shall not be chipped or broken in such a manner as to decrease their strength materially or to admit earth into the drain.

Use of the Terms Vitrified and Hard Burned

46. All drain tile shall be sufficiently "vitrified" or "hard-burned" to afford the degree of supporting strength, percentage of absorption, and resistance to freezing and thawing specified in the physical test requirements prescribed in Table I.

Appeal from Results of Visual Inspection

47. The manufacturer or other seller may appeal from decisions of the inspector on questions of strength or structure when such decisions are based on visual inspection alone, in which case the point at issue shall be determined by standard physical tests, the cost of which shall be paid by the appellant, if the inspector was right, or by the purchaser if his inspector was in error.

Additional Distinctive Characteristics

48. Drain tile of the different classes shall, in addition to all requirements heretofore specified, have the distinctive physical characteristics prescribed in Table III.

TESTING, INSPECTION, AND REJECTION

Making and Reporting Tests

49. All tests shall be made by experts employed by the purchaser. Full reports of all tests shall be furnished the manufacturer or other seller on his request. Tests shall be made and reported promptly.

TABLE III.—DISTINCTIVE GENERAL PHYSICAL PROPERTIES OF DIFFERENT CLASSES OF DRAIN TILE.

Physical Properties Specified.	Farm Drain Tile.	Standard Drain Tile.	Extra-Quality Drain Tile.
Allowable variation of average diameter below specified diameter, per cent	5	3	3
Allowable variation between maximum and minimum diameters of same tile, or average diameters of adjoining tile, percentage of thickness of wall	85	75	65
Allowable variation from straightness, percentage of length	5	3	3
Allowable thickness of exterior blisters, lumps, and flakes which do not weaken tile and are few in number, percentage of thickness of wall	25	20	15
Allowable diameters of above blisters, lumps, and flakes, percentage of internal diameter	20	15	10
General inspection	careful	rigid	very rigid

Expense of Making Tests

50. The purchaser shall pay the expense of making all tests except as otherwise specified in Sections 9, 34, 35, 47, and 52.

Number of Tests

51. The number of standard tests to be made shall be determined by the purchaser.

General Tests and Inspection at Factory

52. In all contracts for ten or more carloads of tile, preliminary general tests and inspection shall be made at the place of manufacture by the purchaser upon demand of the manufacturer or other seller. The expense of such tests and inspection shall be paid by the manufacturer or other seller.

Inspector

53. The inspector shall be employed by the purchaser.

Inspection

54. The manufacturer or other seller of the drain tile shall afford the inspector all reasonable facilities for his work, both as to the selection of specimens for tests, and as to visual inspection. Inspection shall be completed promptly.

Rejection

55. The inspector shall plainly mark all drain tile which he rejects, and such rejected tile shall be removed promptly by the manufacturer or other seller. Upon request of the purchaser, the manufacturer or other seller shall give full account of the removal of rejected tile.

Standard Specifications for

CONCRETE SEWER PIPE[1]

A.S.T.M. Designation: C 14 - 41

ADOPTED, 1920; REVISED, 1924, 1935, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 14; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover nonreinforced concrete pipe intended to be used for the conveyance of sewage, industrial wastes, and storm water.

Class

2. Pipe manufactured according to these specifications shall be known as "Standard Nonreinforced Concrete Sewer Pipe."

Basis of Acceptance

3. The acceptability of the pipe shall be determined by the results of the strength, absorption, and hydrostatic tests prescribed in these specifications, if and when required, and by inspection to determine whether the pipe conforms to these specifications as to design and freedom from defects.

MATERIALS

Concrete

4. The concrete shall consist of portland cement, mineral aggregates, and water.

Cement

5. Portland cement shall conform to the requirements for type I or type III as prescribed in the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

Aggregates

6. Aggregates shall conform to the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33) of the American Society for Testing Materials.[3]

Mixture

7. The aggregates shall be so graded and proportioned and thoroughly mixed

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-13 on Concrete Pipe.

[2] Prior to adoption as standard, these specifications were published as tentative from 1917 to 1920, being revised in 1918, 1919, and 1920.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

in a batch mixer with such proportions of cement and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of these specifications. In no case, however, shall the proportion of portland cement in the mixture be less than six U. S. standard bags (94 lb.) per cubic yard of concrete.

PHYSICAL TEST REQUIREMENTS

Crushing Strength and Absorption

8. The crushing strength and absorption of nonreinforced concrete sewer pipe shall conform to the requirements prescribed in Table I. The individual results of the various tests for each size of pipe and for each shipment and plant shall be tabulated separately so as to show the percentage that fails to conform to the requirements of each test.

TABLE I.—PHYSICAL TEST REQUIREMENTS OF CONCRETE SEWER PIPE.

NOTE.—For pipe 24 to 108 in. in internal diameter, see the Standard Specifications for Reinforced Concrete Sewer Pipe (A.S.T.M. Designation: C 75) of the American Society for Testing Materials.[3]

Internal Diameter, in.	Average Strength, lb. per linear foot		Maximum Absorption, per cent
	Three-Edge-Bearing Method[a]	Sand-Bearing Method[b]	
4	1000	1500	8
6	1100	1650	8
8	1300	1950	8
10	1400	2100	8
12	1500	2250	8
15	1750	2620	8
18	2000	3000	8
21	2200	3300	8
24	2400	3600	8

[a] See Section 15.
[b] See Section 16.

Hydrostatic Test

9. When subjected to the internal hydrostatic pressures specified in Section 19, the pipe shall show no leakage. Moisture appearing on the surface of the pipe in the form of patches or beads adhering to the surface shall not be considered leakage.

Test Specimens

10. (*a*) The specimens to be tested shall be selected by the purchaser or his representative at the point or points designated by him when placing the order.

(*b*) The manufacturer or seller shall furnish, without charge, specimens for tests, up to 0.5 per cent of the number of pipe of each size included in the order, except that in no case shall less than two specimens be furnished. The test specimens shall be sound, full-size pipe.

Measurement and Observation of Specimens

11. (*a*) The test specimens shall first be freed from all visible moisture. When dry, each specimen shall be weighed, measured, and inspected. The results of these observations shall be recorded.

(*b*) *Defective Specimens.*—Specimens which, when placed in a vertical position, do not give a metallic ring when struck with a hammer, or are observed to have cracks or other defects in form or dimensions in excess of the limits permitted in these specifications, shall be discarded and replaced with additional specimens from the shipment.

Crushing Strength Tests

Crushing Strength Tests

12. Pipe shall be tested for crushing strength by either the three-edge-bearing method or the sand-bearing method as described in the following Sections 15 and 16. Either of the two specified bearing methods may be used on retests as provided for in Section 20 (*a*) and (*b*).

Number of Tests

13. The crushing strength test shall ordinarily be applied to not less than

75 per cent of the specimens received for purpose of tests.

Apparatus and Application of Load

14. (*a*) Any prime mover or hand-power device that will apply the load at a uniform rate of about 2000 lb. per min., or in increments of not more than 100 lb. at the same rate, may be used in making the test.

(*b*) The center of the load shall be applied to the top bearing block at a point distant from the spigot end of the pipe equal to one half of the over-all length of the pipe. The test load shall be applied to the upper bearing block in such a way as to leave the bearing free to move in a vertical plane passing midway between the lower bearings. In testing pipe that is "out of straight," the lines of the bearings chosen shall be from those which appear to give most favorable conditions for fair test.

(*c*) The pipe shall not be allowed to stand under load longer than is required to apply the load and to observe and record it.

(*d*) The testing machine shall be substantial and rigid throughout, so that the distribution of the load will not be affected appreciably by the deformation or yielding of any part. The bearings shall be sufficiently rigid to transmit and receive uniform loads throughout their lengths without deflection, and shall be so attached to the machine as to transmit and receive the maximum stresses produced by the tests without lost motion, vibration, or sudden shock.

(*e*) The bearings and the specimen shall be accurately centered so as to secure a symmetrical distribution of the loading on each side of the center of the pipe in every direction.

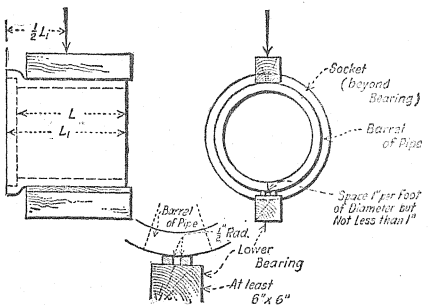

FIG. 1.—Three-Edge Bearings.

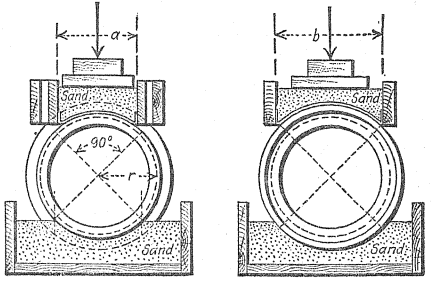
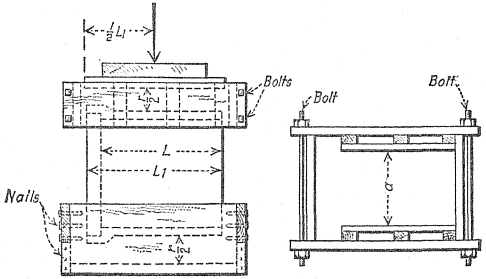


(*f*) The load shall be applied until the pipe yields by cracks passing through the shell.

(*g*) The crushing strength shall be calculated by dividing the total load required to break each pipe by the laying length of the barrel of the pipe, measuring from the bottom of the socket to the end of the spigot.



Three-Edge-Bearing Method

15. When the three-edge-bearing method (see Fig. 1) is used, the ends of each specimen of pipe shall be accurately marked in halves of the circumference prior to the test. The lower bearings

shall consist of two wooden strips with vertical sides having their interior top corners rounded to a radius of approximately $\frac{1}{2}$ in. The strips shall be straight and shall be securely fastened to a rigid block at least 6 by 6 in. in cross-section. the pipe is placed, a fillet of plaster of Paris and sand thick enough to compensate for the inequalities of the pipe barrel shall be cast on the surface of the lower bearings. The pipe shall be placed upon the fillet while the plaster

Bedding of Barrel. Bedding of Socket.

Side View. Upper Bearing Frame.

FIG. 2.—Sand Bearings.

The interior vertical sides of the strips shall be parallel and spaced a distance apart of 1 in. per foot of pipe diameter but in no case less than 1 in. If requested by the manufacturer or the purchaser prior to the test, before of Paris is still somewhat plastic. The upper bearing shall be a rigid wooden block at least 6 by 6 in. in cross-section, straight and true from end to end. A fillet of plaster of Paris may also be cast along the length of the crown of the

pipe to equalize the bearing. The upper bearing shall be brought in contact while the plaster of Paris is still somewhat plastic. The upper and lower bearings shall extend the full length of the pipe exclusive of the socket.

Sand-Bearing Method

16. (*a*) When the sand-bearing method (see Fig. 2) is used, the ends of each specimen of pipe shall be accurately marked in quarters of the circumference prior to the test. Specimens shall be carefully bedded in sand, above and below, for one fourth the circumference of the pipe measured on the middle line of the barrel. The depth of the bedding above and below the pipe at the thinnest points shall be one half the radius of the middle line of the barrel.

(*b*) The sand used shall be clean and shall contain not less than 5 per cent of moisture, and shall be such as will pass a 4760-micron (No. 4) sieve. The sand in the lower bearing shall be loose when the pipe is placed.

(*c*) The top bearing frame shall not be allowed to come in contact with the pipe nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck off level with a straightedge, and shall be covered with a rigid top bearing plate, the lower surface of which is a true plane, made of heavy timbers or other rigid material capable of distributing the test load uniformly without appreciable bending The test load shall be applied at the exact center of this top bearing plate, in such a manner as to permit free motion of the plate in all directions. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used.

(*d*) The test may be made without the use of a testing machine, by piling weights directly on a platform resting on the top bearing plate; provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the pipe, and that the platform shall not be allowed to touch the top bearing frame.

(*e*) The frames of the top and bottom bearings shall be made of timbers so heavy as to avoid appreciable bending by the side pressure of the sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the pipe during the test. A strip of cloth may be attached, if desired, to the inside of the upper frame on each side, along the lower edge, to prevent the escape of sand between the frame and the pipe.

Absorption Test

Absorption Test

17. Absorption tests shall be made in accordance with the procedure described in the following Paragraphs (*a*) to (*e*):

(*a*) *Test Specimens.*—The number of absorption test specimens shall be equal to the number of pipe provided for testing. The specimens shall be obtained from pipe that are acceptable as to strength, and shall be taken from pipe used in making the strength test after that test is made. The specimens shall be marked with the number or identification mark of the pipe from which they were taken. Each specimen shall have an area of 12 to 20 sq. in., as measured on one surface of the pipe, and a thickness equal to the full depth of the pipe shell, and shall be free from visible cracks.

(*b*) *Drying Specimens.*—Specimens shall be dried at a temperature not to exceed 230 F. (110 C.) until two successive weighings at intervals of not less than 2 hr. show an increment of loss not greater than 0.1 per cent of the original weight of the specimen.

(*c*) *Immersion and Reweighing.*—The dried specimens shall be placed in a

suitable receptacle, covered with distilled water or rain water, raised to the boiling point and boiled for 5 hr., and then cooled in water to a final temperature of from 59 to 68 F. (15 to 20 C.). When cool, the specimens shall be removed from the water and allowed to drain for not more than 1 min. The superficial water shall then be removed by a towel or blotting paper, and the specimens immediately weighed.

(*d*) *Weighing Apparatus.*—The balance used shall be sensitive to 0.5 g. when loaded with 1 kg., and weighings shall be read at least to the nearest gram. When other than metric weights are used, the same degree of accuracy shall be obtained.

(*e*) *Calculations and Report.*—The increase in weight of the boiled specimen over its dry weight shall be taken as the absorption of the specimen, and shall be expressed as a percentage of the dry weight. The results shall be reported separately for each specimen.

Hydrostatic Test

Number of Tests

18. Sound, full-size pipe not exceeding about 25 per cent of the specimens received for purpose of tests in each size of pipe, shall be tested for leakage under internal hydrostatic pressure.

Hydrostatic Test

19. (*a*) The ends of the pipe shall be tightly closed by wooden or metallic bulkheads or covers faced with rubber or leather so that no leakage shall occur through the covers at the test pressure. One cover shall be provided with a $\frac{3}{4}$-in. nipple passing through the cover, and held securely in place and made watertight by means of locknuts and washers or gaskets. The outer end of the nipple shall be connected with a pump discharge or water service line.

(*b*) Water pressures, as measured by a standardized gage attached to the delivery pipe close to the specimen, shall be internally applied to the specimen as follows:

5 psi. for 5 min.
10 psi. for 10 min.
15 psi. for 15 min.

ACCEPTANCE OR REJECTION ON RESULTS OF TESTS

Acceptance or Rejection

20. (*a*) Failure of 20 per cent of the specimens to meet the requirements of any of the tests specified in Sections 4 to 19 shall result in rejection of all the pipe in the shipment or delivery, corresponding to the sizes thus failing to comply; except that in the event of 20 per cent of the specimens in any size failing to meet the requirements, the manufacturer or seller may, with the consent of the purchaser, furnish for test, without charge, additional specimens from the same shipment to be selected as specified in Section 10. In case more than 80 per cent of the specimens tested, including those first tested, shall show substantial conformance for each of the various tests performed, then the entire shipment or delivery for this size shall be accepted; otherwise it shall be rejected.

(*b*) In addition to the requirements in Paragraph (*a*), failure of individual specimens tested to develop 75 per cent of the average crushing strength requirements shall be cause for rejection of the shipment, but the manufacturer or seller may cull the pipe and submit the balance of the shipment for retest, and if the shipment then conforms to all of the requirements of these specifications it shall be accepted.

SIZES AND PERMISSIBLE VARIATIONS

Sizes and Dimensions

21. Pipe shall be furnished of the sizes, internal diameters, and dimensions prescribed in Tables II and III. Where several lengths are mentioned in the table the purchaser shall indicate, at

the time of purchase, which lengths shall be furnished; and unless so indicated, the manufacturer shall furnish such lengths as he may elect.

TABLE II.—DIMENSIONS OF CONCRETE SEWER PIPE.

NOTE.—For pipe 24 to 108 in. in internal diameter, see the Standard Specifications for Reinforced Concrete Sewer Pipe (A.S.T.M. Designation: C 75) of the American Society for Testing Materials.[3]

Internal Diameter (*D*), in.	Laying Length (*L*), ft.	Inside Diameter of Socket (*D*$_s$), in.[a]	Depth of Socket (*L*$_s$), in.	Minimum Taper of Socket (*H*)	Thickness of Barrel (*T*), in.	Thickness of Socket (*T*$_s$)
4....	2, 2½, 3	6	1½	1:20	⅝	The thickness of the socket ¼ in. from its outer end shall be not less than three fourths of the thickness of the barrel of the pipe.
6....	2, 2½, 3	8¼	2	1:20	⅝	
8....	2, 2½, 3, 4	10¾	2¼	1:20	⅝	
10....	2, 2½, 3, 4	13	2½	1:20	⅞	
12....	2, 2½, 3, 4	15¼	2½	1:20	1	
15....	2, 2½, 3, 4	18¾	2½	1:20	1¼	
18....	2, 2½, 3, 4	22¼	2¾	1:20	1½	
21....	2, 2½, 3, 4	26	2¾	1:20	1¾	
24....	2, 2½, 3, 4	29½	3	1:20	2	

[a] When pipes are furnished having an increase in thickness over that given in last column, then the diameter of socket shall be increased by an amount equal to twice the increase of thickness of barrel.

TABLE III.—PERMISSIBLE VARIATIONS IN DIMENSIONS OF CONCRETE SEWER PIPE.

NOTE.—For pipe 24 to 108 in. in internal diameter, see the Standard Specifications for Reinforced Concrete Sewer Pipe (A.S.T.M. Designation: C 75) of the American Society for Testing Materials.[3]

Nominal Size, Internal Diameter, in.	Limits of Permissible Variation in:				
	Length, in. per ft. (−)[a]	Internal Diameter, in.		Depth of Socket, in. (−)[a]	Thickness of Barrel, in. (−)[a]
		Spigot (±)[a]	Socket (±)[a]		
4.....	1/4	1/16	1/16	1/16	1/16
6.....	1/4	5/64	5/64	1/16	1/16
8.....	1/4	1/16	1/16	1/16	1/16
10.....	1/4	1/16	1/16	1/16	1/16
12.....	1/4	1/16	1/16	1/16	1/16
15.....	1/4	1/16	1/16	1/16	1/16
18.....	1/4	1/16	1/16	1/16	1/16
21.....	1/4	5/64	5/64	1/16	1/16
24.....	5/8	5/64	5/64	1/16	1/16

[a] The minus sign (−) alone indicates that the plus variation is not limited; the plus and minus sign (±) indicates variation in both excess and deficiency in dimension.

Permissible Variations in Dimensions

22. The permissible variations from the dimensions prescribed in Table II shall not exceed those stated in Table III. Where the thickness of barrel is increased beyond that given in Table II in order to meet the specified requirements of strength, the diameter at the inside of the socket shall be increased by double the increase in thickness of the barrel. Pipe intended to be straight shall not have variation in alignment of more than $\frac{1}{8}$ in. per foot of length.

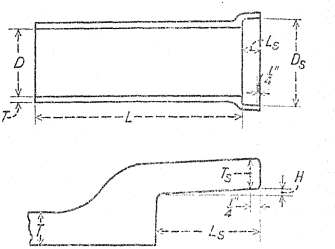


FIG. 3.—Application of Dimensions Given in Table II.

WORKMANSHIP AND FINISH

Absence of Defects

23. Pipes shall be substantially free from fractures, large or deep cracks and blisters, laminations, and surface roughness.

Finish of Ends

24. The ends of the pipes shall be square with their longitudinal axis.

Specials

25. (*a*) Special shapes shall have a plain spigot end and a socket end corresponding in all respects with the dimensions specified for pipe of the corresponding internal diameter. Branches shall be furnished to lay the same lengths as straight pipe. All specials shall conform in finish to the specifications for pipes given in Sections 23 and 24.

(*b*) Slants shall have their spigot ends cut at an angle of approximately 45 deg. with the longitudinal axis.

(*c*) Curves shall be at angles of 90, 45, 22½ deg., as required. They shall con-

form substantially to the curvature specified.

(*d*) Branches shall be furnished with the connection or connections of the size or sizes specified, securely and completely fastened in the process of manufacture to the barrel of the pipe. T-branches and double T-branches shall have their axes perpendicular to the longitudinal axis of the pipe. Y-branches, double Y-branches, and V-branches shall have their axes approximately 45 deg. from the longitudinal axis of the pipe measured from the socket end. All branches shall terminate in sockets, and the barrel of the branch shall be of sufficient length to permit making a proper joint when the connecting pipe is inserted in the branch socket.

(*e*) Channel or split pipe, curves and branches shall be accurate half sections of the corresponding size of pipe or other specials.

MARKING

Marking

26. Each length of pipe shall bear the initials or name of the person, company, or corporation by whom manufactured, and the location of the plant. The markings shall be indented or stenciled on the exterior or interior of the barrel near the socket and shall be plainly legible for purpose of identification.

INSPECTION AND REJECTION

Inspection

27. Each length of pipe shall be subject to inspection at the factory, trench, or other point of delivery by a competent inspector employed by the purchaser. The purposes of the inspection shall be to cull and reject pipe which, independent of the physical tests herein specified, fails to conform to the requirements of these specifications.

Rejection

28. Pipe shall be subject to rejection on account of any of the following:

(*a*) Variations in any dimension exceeding the permissible variations prescribed in Table III.

(*b*) Fractures or cracks passing through the shell or socket, except that a single crack not exceeding 2 in. in length at either end of a pipe or a single fracture in the socket not exceeding 3 in. in width nor 2 in. in length shall not be considered cause for rejection unless these defects exist in more than 5 per cent of the entire shipment or delivery.

(*c*) Blisters where the surface is broken or which project more than $\frac{1}{8}$ in. above the surface.

(*d*) Defects that indicate imperfect mixing and molding.

(*e*) Cracks sufficient to impair the strength, durability, or serviceability of the pipe.

(*f*) Variation of more than $\frac{1}{8}$ in. per linear foot in alignment of pipe intended to be straight.

(*g*) Failure to give a clear ringing sound when placed on end and dry-tapped with a light hammer.

(*h*) Insecure attachment of branches on spurs.

(*i*) The complete absence of distinct web-like markings, which is indicative of a possible deficiency of water in the concrete mix, from the external surface of pipe made by any process in which the forms are removed immediately after the concrete has been placed.

Marking of Rejected Specimens

29. All rejected pipe shall be plainly marked by the inspector and shall be replaced by the manufacturer or seller with pipe which will meet the requirements of these specifications, without additional cost to the purchaser.

Standard Specifications for

REINFORCED CONCRETE SEWER PIPE[1]

A.S.T.M. Designation: C 75 – 41

ADOPTED, 1935; REVISED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 75; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover reinforced concrete pipe intended to be used for the conveyance of sewage, industrial wastes, and storm water.

Class

2. Pipe manufactured according to these specifications shall be known as "Standard Reinforced Concrete Sewer Pipe."

Basis of Acceptance

3. The acceptability of the pipe shall be determined by the results of the strength and absorption tests prescribed in these specifications, if and when required, and by inspection to determine whether the pipe conforms to these specifications as to design and freedom from defects.

MATERIALS

Reinforced Concrete

4. The reinforced concrete shall consist of portland cement, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and the concrete act together.

Cement

5. Portland cement shall conform to the requirements for type I or type III as prescribed in the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

Steel Reinforcement

6. Reinforcement may consist either of wire conforming to the Standard Specifications for Cold-Drawn Steel Wire for Concrete Reinforcement (A.S.T.M. Designation: A 82),[4] or of bars of structural or intermediate grade conforming to the Standard Specifications for Billet-Steel Bars for Concrete Rein-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-13 on Concrete Pipe.

[2] Prior to adoption as standard, these specifications were published as tentative from 1930 to 1935, being revised in 1934 and 1935.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] 1944 Book of A.S.T.M. Standards, Part I.

forcement (A.S.T.M. Designation: A 15)[4] of the American Society for Testing Materials.

Aggregates

7. Aggregates shall conform to the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33) of the American Society for Testing Materials.[3]

shall the proportion of portland cement in the mixture be less than six U. S. standard bags (94 lb.) per cubic yard of concrete.

DESIGN

Minimum Designs

9. The shell thickness and the amount of circumferential reinforcement shall

TABLE I.—DESIGN AND STRENGTH TEST REQUIREMENTS OF STANDARD REINFORCED CONCRETE SEWER PIPE.

NOTE.—For pipe 4 to 24 in. in internal diameter, see the Standard Specifications for Concrete Sewer Pipe (A.S.T.M. Designation: C 14) of the American Society for Testing Materials.[3]

108	....	....	....	....	9	2 lines[b] totalling 0.67	....	....	....	....

[a] The distance from the center line of the reinforcement to the nearest surface of the concrete has been assumed in the design tables as 1 in.

[b] Where two lines of steel are specified, a single line placed elliptically may be used, and the area of this shall be at least 50 per cent of the total steel area specified in the design table.

Mixture

8. The aggregates shall be so graded and proportioned and thoroughly mixed in a batch mixer with such proportions of cement and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of these specifications. In no case, however, be not less than the minimum design requirements prescribed in Table I.

Alternate Designs

10. Manufacturers may submit to the purchaser, for approval, designs other than those in Table I, provided that such pipe shall conform to the same

physical tests and inspection requirements prescribed in these specifications for the pipe for which it is substituted. In no alternate design, however, shall the shell thickness be less than that prescribed in Table I.

Placing Reinforcement

11. When two lines of reinforcement are used in circular pipe, one shall be placed near the inner and one near the outer surfaces of the pipe. When a single line of circular reinforcement is used in circular pipe, it shall be placed near the inner surface of the pipe shell. The single line of elliptical reinforcement used in circular pipe, or the single line of circular reinforcement in elliptical pipe shall be placed near the inner surface at the "top" and "bottom" of the pipe and near the outer surface at the sides (see Section 32 (*d*)).

Longitudinals

12. Each line of circumferential reinforcement shall be assembled into a cage which shall contain sufficient longitudinal bars or members, extending through the barrel of the pipe, to maintain the reinforcement rigidly in exact shape and correct position within the form.

Laps, Welds, and Spacing

13. If the splices are not welded, the reinforcement shall be lapped not less than 30 diameters for bars, and 40 diameters for cold-drawn wire. If welded, the member at either a welded splice or intersection shall develop a tensile strength not less than the minimum strength required for the reinforcement by the applicable specifications cited in Section 6. The spacing center to center of adjacent rings of circumferential reinforcement in a cage shall not exceed 4 in. for pipe up to and including 48 in. in diameter, nor exceed the shell thickness for larger pipe, and shall in no case exceed 6 in.

Joints

14. The ends of reinforced concrete sewer pipe shall be so formed that when the pipe are laid together and the joints cemented, they will make a continuous and uniform line of pipe with a smooth and regular interior surface. The joints shall be of such design as will permit effective cementing to reduce leakage and infiltration to a satisfactory minimum and to permit placement without appreciable irregularities in the flow line.

Joint Reinforcement

15. In all pipe 36 in. or more in diameter, the joint shall have a circumferential reinforcement equal in area to that of a single line within the barrel of the pipe.

PHYSICAL TEST REQUIREMENTS

Strength Requirements

16. The ultimate load, as determined by either of the methods described in Sections 23 and 24, shall be not less than the ultimate load prescribed in Table I. When the test load reaches the cracking load given in the table for the size of pipe tested, there shall be in the barrel of the pipe no crack having a width of 0.01 in. or more for a length of 1 ft. or more. The crack shall be considered 0.01 in. in width when the point of the measuring gage will, without forcing, penetrate it $\frac{1}{16}$ in. at close intervals throughout the specified distance of 1 ft. The width of crack shall be measured by means of a gage made from a leaf 0.01 in. in thickness (as in a set of standard machinist's gages), ground to a point $\frac{1}{16}$ in. in width, with corners rounded, and a taper of $\frac{1}{4}$ in. per inch, as illus-

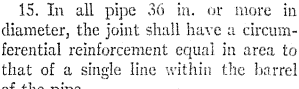

FIG. 1.—Gage Leaf for Measuring Cracks.

trated in Fig. 1. The ultimate load is reached when the pipe will sustain no greater load.

Strength Requirements, Elliptical Pipe

17. Elliptical pipe shall conform to the test requirements for circular pipe having the same horizontal internal diameter.

Test Requirements and Acceptability Under Absorption Tests

18. The absorption, determined as specified in Section 27, shall not exceed 8 per cent of the dry weight. Pipe shall be considered as conforming to these specifications for absorption when not less than 80 per cent of the number of specimens tested, including any retested, conform to the test requirements. When the initial absorption specimen from a pipe fails to conform to these specifications, the absorption test shall be made on another specimen from the same pipe and the results of the retest shall be substituted for the original test results.

Crushing Strength Tests

Test Specimens

19. The specified number of pipe for purpose of tests shall be furnished without charge by the manufacturer and shall be selected at random by the purchaser, and shall be pipe which would not otherwise be rejected under these specifications. The selection shall be made at the point or points designated by the purchaser when placing the order. The test specimens shall be surface-dry when tested and shall not have been exposed to a temperature below 40 F. (5 C.) for the 24 hr. immediately preceding the test.

Preliminary Tests and Tests for Extended Deliveries

20. A purchaser of pipe, whose needs require shipments at intervals over extended periods of time, shall be entitled to preliminary tests of not more than three sections of pipe covering each size, 12 to 72 in. in diameter, in which he is interested. The acceptability of 78- to 108-in. pipe shall be determined by tests of the quality of the concrete as placed in the pipe and by examination of the quality, amount, and accuracy of placement of the reinforcement. The strength of the concrete shall be determined from 6 by 12-in. test cylinders made from the concrete used in making the pipe and manufactured and cured under identical conditions with the pipe. Compression tests of such cylinders shall be made in accordance with the Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39) of the American Society for Testing Materials.[3] After these preliminary tests, a purchaser shall be entitled to additional tests in such numbers and at such times as he may deem necessary, provided that the total number of pipe tested shall not exceed 0.5 per cent of the pipe delivered.

Crushing Strength Tests

21. Pipe may be tested for strength by either the three-edge-bearing method or the sand-bearing method, as described in Sections 23 and 24.

Apparatus

22. (*a*) In making the test, any mechanical or hand-power device may be used in which the head that applies the load moves at such a speed as to increase the load at a uniform rate of approximately 2000 lb. per linear foot of pipe per minute.

(*b*) It is necessary that the testing machine used for the strength tests shall produce a uniform deflection throughout the full length of the pipe. The testing machine shall be substantial and rigid throughout, so that the distribution of

the load will not be affected appreciably by the deformation or yielding of any part.

(*c*) The load shall be applied continuously until the required strength of the pipe specified in Table I is reached. The load per linear foot of pipe shall be calculated by dividing the total recorded load by the laying length. The pipe shall not be allowed to stand under load longer than is required to apply the load and to observe and record it. The pipe shall be surface-dry when tested.

Three-Edge-Bearing Method

23. When the three-edge-bearing method is used (see Figs. 2 and 3), the ends of each specimen of pipe shall be accurately marked in halves of the circumference prior to the test. The lower bearings shall consist of two wooden strips with vertical sides having their interior top corners rounded to a radius of approximately $\frac{1}{2}$ in. The strips shall be straight and shall be securely fastened to a rigid base. The interior vertical

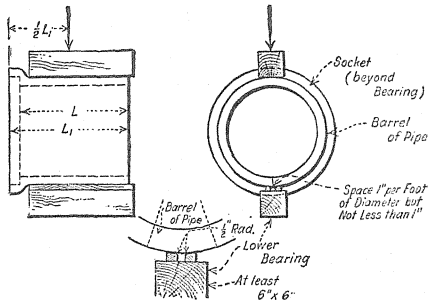

FIG. 2.—Three-Edge Bearings.

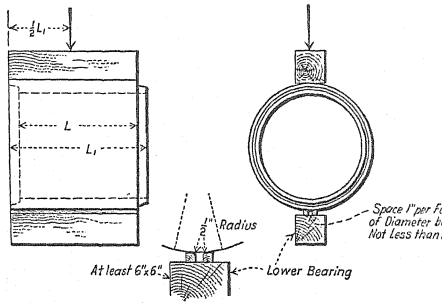

FIG. 3.—Three-Edge Bearings.

sides of the strips shall be parallel and spaced a distance apart of 1 in. per foot of pipe diameter, but in no case less than 1 in. The upper bearing shall be a rigid wooden block, straight and true from end to end. The upper and lower bearings shall extend the full length of the pipe exclusive of the bell. The pipe shall be placed symmetrically between the two bearings as illustrated in Figs. 2 and 3. In testing pipe which is "out of line," the lines of the bearings chosen shall be from those which appear to give the most favorable conditions for fair test.

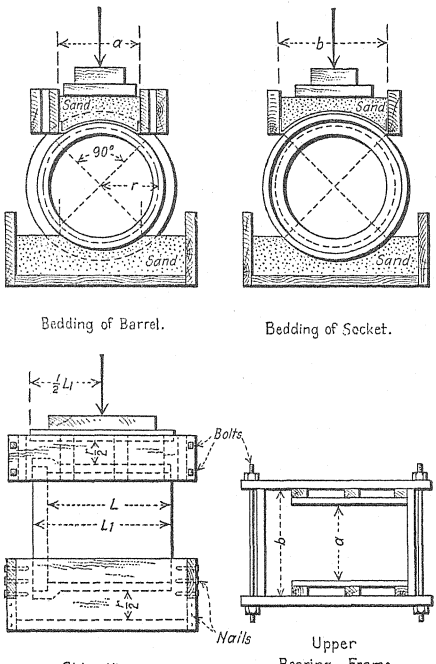

FIG. 4.—Sand Bearings.

Sand-Bearing Method

24. (*a*) When the sand-bearing method is used (see Figs. 4 and 5), the ends of each specimen of pipe shall be accurately marked in quarters of the cir-

cumference prior to the test. Specimens shall be carefully bedded in sand, above and below, for one fourth the circumference of the pipe measured on the middle line of the barrel. The depth of bedding above and below the pipe at the thinnest points shall be one half the radius of the middle line of the barrel.

(*b*) The sand used shall be clean and shall contain not less than 5 per cent of moisture, and shall be such as will pass a 4760-micron (No. 4) sieve. The sand in the lower bearing shall be loose when the pipe is placed.

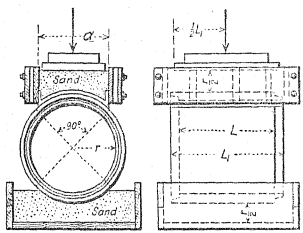

FIG. 5.—Sand Bearings.

(*c*) The top bearing frame shall not be allowed to come in contact with the pipe nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck off level with a straightedge, and shall be covered with a rigid top bearing plate, the lower surface of which is a true plane, made of heavy timbers or other rigid material capable of distributing the test load uniformly without appreciable bending. The test load shall be applied at the exact center of this top bearing plate, or in such manner as to produce uniform deflection throughout the full length of the pipe. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used.

(*d*) The test may be made without the use of a testing machine, by piling weights directly on a platform resting on the top bearing plate; provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the pipe, and that the platform shall not be allowed to touch the top bearing frame.

(*e*) The frames of the top and bottom bearings shall be made of timbers so heavy as to avoid appreciable bending by the side pressure of the sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the pipe during the test. A strip of cloth may be attached, if desired, to the inside of the upper frame on each side, along the lower edge, to prevent the escape of sand between the frame and the pipe.

Acceptability and Retests

25. (*a*) Should the test specimens selected by the purchaser conform to the test requirements, then all pipe represented by such specimens shall be accepted as to strength, provided the pipe shall otherwise conform to the specifications.

(*b*) Should any of the specimens first tested fail to conform to the test requirements, then the manufacturer shall have the right to additional tests of the size or sizes of pipe which have failed. If the strength attained by a specimen is less than the strength required, in the amounts shown in the first column of the following table, additional tests shall be made upon pipe to the number specified below, for each pipe of deficient strength:

Percentage of Required Strength	Number of Pipe for Retest
Less than 100 and more than 90 per cent	2
Less than 90 and more than 80 per cent	3
Less than 80 and more than 70 per cent	4

If the additional pipe so tested all conform to the test requirements, then all pipe represented by such tests shall be accepted; otherwise they shall be rejected, unless other tests, agreed upon by the purchaser and manufacturer, demonstrate to the satisfaction of the purchaser, the acceptability of the pipe. This latter provision, as to tests by agreement, shall also apply in the event that the strength attained by a pipe under test is less than 70 per cent of the required strength.

Concrete Tests and Reinforcement Examination

26. By agreement between the purchaser and the manufacturer, the acceptability of all sizes of pipe may be determined by tests of the quality of concrete as placed in the pipe and the examination of the quality, amount, and accuracy of placement of the reinforcement. The strength of the concrete shall be determined as specified in Section 20.

Absorption Test

Absorption Test

. 27. Absorption tests shall be made in accordance with the procedure described in the following Paragraphs (*a*) to (*e*):

(*a*) *Test Specimens.*—The number of absorption test specimens shall be equal to the number of pipe provided for testing. The specimens shall be obtained from pipe that are acceptable as to strength, and shall be taken from pipe used in making the strength test after that test is made. The specimens shall be marked with the number or identification mark of the pipe from which they were taken. Each specimen shall have an area of 16 to 24 sq. in., as measured on one surface of the pipe, and a thickness equal to the full depth of the pipe shell, and shall be free from visible cracks.

(*b*) *Drying Specimens.*—Specimens shall be dried at a temperature not to exceed 230 F. (110 C.) until two successive weighings at intervals of not less than 2 hr. show an increment of loss not greater than 0.1 per cent of the original weight of the specimen.

(*c*) *Immersion and Reweighing.*—The dried specimens shall be placed in a suitable receptacle, covered with distilled water or rain water, raised to the boiling point and boiled for 5 hr., and then cooled in water to a final temperature of from 59 to 68 F. (15 to 20 C.). When cool, the specimens shall be removed from the water and allowed to drain for not more than 1 min. The superficial water shall then be removed by a towel or blotting paper, and the specimens immediately weighed.

(*d*) *Weighing Apparatus.*—The balance used shall be sensitive to 0.5 g. when loaded with 1 kg., and weighings shall be read at least to the nearest gram. When other than metric weights are used, the same degree of accuracy shall be obtained.

(*e*) *Calculations and Report.*—The increase in weight of the boiled specimen over its dry weight shall be taken as the absorption of the specimen, and shall be expressed as a percentage of the dry weight. The results shall be reported separately for each specimen.

Test Equipment

28. Every manufacturer furnishing pipe under these specifications shall furnish all facilities necessary to carry out the tests required in these specifications.

SIZES AND PERMISSIBLE VARIATIONS

Standard Sizes

29. Pipe of the internal diameters listed in Table I shall be considered

standard sizes. In elliptical pipe, the inside diameter at the minor axis shall be equal to the diameter of the corresponding size of circular pipe.

Permissible Variations in Dimensions

30. (*a*) Variations of the internal diameter shall not exceed 1.5 per cent for 12- to 36-in. pipe, inclusive, and 1 per cent for 42- to 108-in. pipe, inclusive. The shell thickness shall not be less than that given in Table I by more than 5 per cent at any point.

(*b*) Variations of the position of the reinforcement shall not exceed $\frac{1}{4}$ in. from the position provided in the design for pipe having an internal diameter of 48 in. or less, and shall not exceed $\frac{1}{2}$ in. for larger pipe; but the cover on the reinforcement shall be not less than $\frac{3}{4}$ in. at any point.

(*c*) The underrun in length of pipe from that specified shall be not more than $\frac{1}{8}$ in. per ft. with a maximum of $\frac{1}{2}$ in. in any length of pipe.

WORKMANSHIP AND FINISH

Finish

31. Pipe shall be substantially free from fractures, large or deep cracks, and surface roughness. The planes of the ends of the pipe shall be perpendicular to their longitudinal axes.

MARKING

Markings

32. The following shall be clearly stenciled on each length of pipe:

(*a*) The pipe class by an "S" for Standard Pipe,

(*b*) The date of manufacture,

(*c*) The name or trade-mark of the manufacturer, and

(*d*) Elliptical pipe with circular reinforcing and circular pipe with elliptical reinforcing shall have the word "Top" or "Bottom" clearly stenciled on the inside of the pipe at the correct place to indicate the proper position when laid.

INSPECTION AND REJECTION

Age for Acceptance

33. Pipe shall be considered ready for acceptance when they conform to the requirements, as indicated by the specified tests.

Inspection

34. The quality of all materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by an inspector employed by the purchaser. The manufacturer, when so directed by the inspector, shall have holes cut in such sections of the finished pipe (not exceeding one hole in every 50 sections delivered), as desired, so that a proper inspection may be made of the quantity and placement of the reinforcement. If the pipe is also tested for strength or absorption, inspection of the reinforcement shall be made on the pipe sections used for those tests, and in no case shall the total number of pipe cut open for inspection of reinforcement exceed the number to which the purchaser is entitled under the provisions of Section 20 or 25.

Rejection

35. Pipe shall be subject to rejection on account of failure to conform to any of the specification requirements or on account of any of the following:

(*a*) Fractures or cracks passing through the shell, except that a single end crack that does not exceed the depth of the joint shall not be cause for rejection. If a single end crack that does not exceed the depth of the joint exists in more than 10 per cent of the pipe inspected, however, the defective pipe shall be rejected.

(*b*) Defects that indicate imperfect mixing and molding.

(*c*) Surface defects indicating honeycombed or open texture.

(*d*) Spalls deeper than one half the depth of the joint or extending more than 4 in. around the circumference. If spalls not deeper than one half the depth of the joint or extending not more than 4 in. around the circumference exist in more than 10 per cent of the pipe, however, the defective pipe shall be rejected.

(*e*) Exposure of the circumferential reinforcement when such exposure would indicate that the reinforcement is misplaced.

(*f*) The complete absence of distinct web-like markings, which is indicative of a possible deficiency of water in the concrete mix, from the external surface of pipe made by any process in which the forms are removed immediately after the concrete has been placed.

Standard Specifications for

REINFORCED CONCRETE CULVERT PIPE[1]

A.S.T.M. Designation: C 76 – 41

ADOPTED, 1937; REVISED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 76; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover reinforced concrete pipe intended to be used for the construction of culverts.

Classes

2. Pipe manufactured according to these specifications shall be of two classes known respectively as "Standard-Strength Reinforced Concrete Culvert Pipe" and "Extra-Strength Reinforced Concrete Culvert Pipe."

Basis of Acceptance

3. The acceptability of the pipe shall be determined by the results of the strength and absorption tests prescribed in these specifications, if and when required, and by inspection to determine whether the pipe conforms to these specifications as to design and freedom from defects.

MATERIALS

Reinforced Concrete

4. The reinforced concrete shall consist of portland cement, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and the concrete act together.

Cement

5. Portland cement shall conform to the requirements for type I or type III as prescribed in the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

Steel Reinforcement

6. Reinforcement may consist either of wire conforming to the Standard Specifications for Cold-Drawn Steel Wire for Concrete Reinforcement (A.S.T.M. Designation: A 82),[4] or of bars of structural or intermediate grade conforming to the Standard Specifications

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-13 on Concrete Pipe.

[2] Prior to adoption as standard, these specifications were published as tentative from 1930 to 1937, being revised in 1935 and 1937.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] 1944 Book of A.S.T.M. Standards, Part I.

TABLE I.—DESIGN AND STRENGTH TEST REQUIREMENTS OF STANDARD-STRENGTH REINFORCED CONCRETE CULVERT PIPE.

Internal Diameter of Pipe, in.	Concrete, 3500 psi.			Concrete, 4500 psi.			Strength Test Requirements, lb. per linear ft. of pipe	
	Minimum Reinforcement,[a] sq. in. per linear ft. of pipe barrel			Minimum Reinforcement,[a] sq. in. per linear ft. of pipe barrel			Three-Edge-Bearing Method[b]	
	Minimum Shell Thickness, in.	Circular Reinforcement in Circular Pipe	Elliptical Reinforcement in Circular Pipe and Circular Reinforcement in Elliptical Pipe	Minimum Shell Thickness, in.	Circular Reinforcement in Circular Pipe	Elliptical Reinforcement in Circular Pipe and Circular Reinforcement in Elliptical Pipe	Load to Produce a 0.01-in. Crack	Ultimate Load
12	2	1 line 0.07	.....	1¾	1 line 0.08	.....	2250	3 500
15	2¼	1 line 0.09	.....	2	1 line 0.11	.....	2625	4 065
18	2½	1 line 0.12	1 line 0.10	2	1 line 0.14	.....	3000	4 500
24	3	1 line 0.17	1 line 0.13	2½	1 line 0.20	1 line 0.17	3000	5 000
30	3½	1 line 0.22	1 line 0.17	3	1 line 0.28	1 line 0.21	3375	5 750
36	4	2 lines, each 0.18	1 line 0.18	3½	2 lines, each 0.22	1 line 0.22	4050	6 600
42	4½	2 lines, each 0.21	1 line 0.21	3½	2 lines, each 0.25	1 line 0.25	4725	7 350
48	5	2 lines, each 0.25	1 line 0.25	4¼	2 lines, each 0.31	1 line 0.31	5400	8 000
54	5½	2 lines, each 0.30	1 line 0.30	4½	2 lines, each 0.37	1 line 0.37	5850	9 000
60	6	2 lines, each 0.33	1 line 0.33	5	2 lines, each 0.41	1 line 0.41	6000	10 000
66	6½	2 lines, each 0.37	1 line 0.37	5½	2 lines, each 0.45	1 line 0.45	6300	11 000
72	7	2 lines, each 0.40	1 line 0.40	6	2 lines, each 0.48	1 line 0.48	6600	12 000
78	7½	2 lines, each 0.43	1 line 0.43	6½	2 lines, each 0.51	1 line 0.51	....	....
84	8	2 lines, each 0.46	1 line 0.46	7	2 lines, each 0.54	1 line 0.54	....	....
90	8	2 lines, each 0.56	1 line 0.56	....	.....	.....	....	....
96	8½	2 lines, each 0.60	1 line 0.60	....	.....	.....	....	....
102	8½	2 lines, each 0.72	1 line 0.72	....	.....	.....	....	....
108	9	2 lines, each 0.78	1 line 0.78	....	.....	.....	....	....

[a] The distance from the center line of the reinforcement to the nearest surface of the concrete has been assumed in th design tables as 1¼ in. for pipe with a shell 2½ in. or more in thickness.
[b] Test loads for sand-bearing tests shall be one and one-half times those specified in this table for the three-edge-bearing tests.

TABLE II.—DESIGN AND STRENGTH TEST REQUIREMENTS OF EXTRA-STRENGTH REINFORCED CONCRETE CULVERT PIPE.

Internal Diameter of Pipe, in.	Concrete, 4500 psi.			Strength Test Requirements, lb. per linear ft. of pipe	
	Minimum Shell Thickness, in.	Minimum Reinforcement,[a] sq. in. per linear ft. of pipe barrel		Three-Edge-Bearing Method[b]	
		Circular Reinforcement in Circular Pipe	Elliptical Reinforcement in Circular Pipe and Circular Reinforcement in Elliptical Pipe	Load to Produce a 0.01-in. Crack	Ultimate Load
24	3	1 line 0.26	1 line 0.20	4 000	6 000
30	3½	1 line 0.31	1 line 0.24	5 000	7 500
36	4	2 lines, each 0.28	1 line 0.28	6 000	9 000
42	4½	2 lines, each 0.33	1 line 0.33	7 000	10 500
48	5	2 lines, each 0.38	1 line 0.38	8 000	12 000
54	5½	2 lines, each 0.44	1 line 0.44	9 000	13 500
60	6	2 lines, each 0.50	1 line 0.50	9 000	15 000
66	6½	2 lines, each 0.56	1 line 0.56	9 500	16 500
72	7	2 lines, each 0.60	1 line 0.60	9 900	18 000
78	7½	2 lines, each 0.65	1 line 0.65	....	....
84	8	2 lines, each 0.72	1 line 0.72	....	....
90	8	2 lines, each 0.84	1 line 0.84	....	....
96	8½	2 lines, each 0.90	1 line 0.90	....	....
102	8½	2 lines, each 1.08	1 line 1.08	....	....
108	9	2 lines, each 1.17	1 line 1.17	....	....

[a] The distance from the center line of the reinforcement to the nearest surface of the concrete has been assumed in the design tables as 1¼ in. for pipe with a shell 2½ in. or more in thickness.
[b] Test loads for sand-bearing tests shall be one and one-half times those specified in this table for the three-edge-bearing tests.

for Billet-Steel Bars for Concrete Reinforcement (A.S.T.M. Designation: A 15)[4] of the American Society for Testing Materials.

Aggregates

7. Aggregates shall conform to the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33) of the American Society for Testing Materials.[3]

Mixture

8. The aggregates shall be so graded and proportioned and thoroughly mixed in a batch mixer with such proportions of cement and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of these specifications. In no case, however, shall the proportion of portland cement in the mixture be less than six U. S. standard bags (94 lb.) per cubic yard of concrete.

DESIGN

Minimum Designs

9. The shell thickness and the amount of circumferential reinforcement shall be not less than that prescribed in Tables I and II.

Alternate Designs

10. Manufacturers may submit to the purchaser, for approval, designs other than those in Tables I and II, provided that such pipe shall conform to the same physical tests and inspection requirements prescribed in these specifications for the pipe for which it is substituted. In no alternate design, however, shall the shell thickness be less than that prescribed in Tables I and II.

Placing Reinforcement

11. In circular pipe having one line of circular reinforcement, the reinforcement in the barrel of the pipe shall be placed equally distant from the inner and outer surfaces of the pipe. In circular pipe having two lines of circular reinforcement, each line shall be so placed that the net protective covering of concrete over the reinforcement in the barrel of the pipe shall be not less than 1 in. In circular pipe having elliptical reinforcement, and in elliptical pipe having circular reinforcement, the reinforcement in the barrel of the pipe shall be so placed that the net protective covering of concrete along the vertical diameter of the pipe shall be not less than 1 in. from the inside surface of the pipe, and the net protective covering of concrete along the horizontal diameter of the pipe shall be not less than 1 in. from the outside surface of the pipe. (See Section 34 (*d*)). The location of the reinforcement shall be subject, however, to the variation permitted in Section 32 (*b*).

Longitudinals

12. Each line of circumferential reinforcement shall be assembled into a cage which shall contain sufficient longitudinal bars or members, extending through the barrel of the pipe, to maintain the reinforcement rigidly in exact shape and correct position within the form.

Laps, Welds, and Spacing

13. If the splices are not welded, the reinforcement shall be lapped not less than 30 diameters for bars, and 40 diameters for cold-drawn wire. If welded, the member at either a welded splice or intersection shall develop a tensile strength not less than the minimum strength required for the reinforcement by the applicable specifications cited in Section 6. The spacing center to center of adjacent rings of circumferential

reinforcement in a cage shall not exceed 4 in. for pipe up to and including 48 in. in diameter, nor exceed the shell thickness for larger pipe, and shall in no case exceed 6 in.

Joints

14. The ends of reinforced concrete culvert pipe shall be of such design that the pipe when laid shall form a continuous conduit with a smooth and uniform interior surface.

Joint Reinforcement

15. In all pipe 36 in. or more in diameter, the joint shall have a circumferential reinforcement equal in area to that of a single line within the barrel of the pipe.

CURING

Curing

16. Pipe shall be subjected to any one of the methods of curing described in the following Paragraphs (*a*) to (*c*) or to any other method or combination of methods, approved by the purchaser, that will give satisfactory results:

(*a*) *Steam Curing.*—Pipe may be placed in a curing chamber, free from outside drafts, and cured in a moist atmosphere, maintained at a temperature between 100 and 130 F. (38 and 54 C.) by the injection of steam for a period of not less than 24 hr. or, when necessary, for such additional time as may be needed to enable the pipe to meet the strength requirements. When a curing chamber is not available, pipe may be placed in an enclosure of canvas or other closely woven material and subjected to saturated steam at the temperature and for the time specified above. The enclosure shall be so erected as to allow full circulation of steam around the entire pipe. The interior surfaces of the curing room or canvas jackets and the surfaces of the pipe shall be entirely moist at all times.

(*b*) *Water Spray Curing.*—Under the conditions of enclosure prescribed in Paragraph (*a*), pipe may be cured by subjecting it to a continuous or frequently applied fine spray of water in an enclosure maintained at a temperature of not less than 70 F. (21 C.) for a period of not less than 72 hr., or such additional time as may be necessary to meet the strength requirements. If the enclosure is maintained at a temperature of less than 70 F. (21 C.), the curing period shall be increased as may be necessary to meet the strength requirements.

(*c*) *Saturated Cover Curing.*—The sides and top of each pipe may be covered with heavy burlap or other suitable material, saturated with water before applying and kept saturated with water at a temperature of not less than 70 F. (21 C.) for 72 hr., or such additional time as may be necessary to meet the strength requirements. The ends of the pipe shall be so enclosed as to prevent the free circulation of air through or around the pipe. If the temperature of the water is less than 70 F. (21 C.), the curing period shall be increased as may be necessary to meet the strength requirements.

PHYSICAL TEST REQUIREMENTS

Strength Requirements

17. The ultimate load, as determined by either of the methods described in Sections 25 and 26, shall be not less than the ultimate load prescribed in Tables I and II. When the test load reaches the cracking load given in the tables for the size and class of pipe

tested, there shall be in the barrel of the pipe no crack having a width of 0.01 in. or more for a length of 1 ft. or more. The crack shall be considered 0.01 in. in width when the point of the measuring gage will, without forcing, penetrate it $\frac{1}{16}$ in. at close intervals throughout the specified distance of 1 ft. The width of crack shall be measured by means of a gage made from a leaf 0.01 in. in thickness (as in a set of standard machinist's gages), ground to a point $\frac{1}{16}$ in. in width, with corners rounded, and a taper of $\frac{1}{4}$ in. per inch, as illustrated in Fig. 1. The ultimate load is reached when the pipe will sustain no greater load.

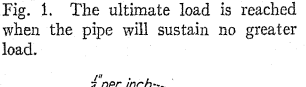

FIG. 1.—Gage Leaf for Measuring Cracks.

Strength Requirements, Elliptical Pipe

18. Elliptical pipe shall conform to the test requirements for circular pipe having the same horizontal internal diameter.

Test Requirements and Acceptability Under Absorption Tests

19. The absorption, determined as specified in Section 29, shall not exceed 8 per cent of the dry weight. Pipe shall be considered as conforming to these specifications for absorption when not less than 80 per cent of the number of specimens tested, including any retested, conform to the test requirements. When the initial absorption specimen from a pipe fails to conform to these specifications, the absorption test shall be made on another specimen from the same pipe and the results of the retest shall be substituted for the original test results.

Crushing Strength Tests

Test Specimens

20. The specified number of pipe for purpose of tests shall be furnished without charge by the manufacturer and shall be selected at random by the purchaser, and shall be pipe which would not otherwise be rejected under these specifications. The selection shall be made at the point or points designated by the purchaser when placing the order. The test specimens shall be surface-dry when tested and shall not have been exposed to a temperature below 40 F. (5 C.) for the 24 hr. immediately preceding the test.

Preliminary Tests and Tests for Extended Deliveries

21. A purchaser of pipe, whose needs require shipments at intervals over extended periods of time, shall be entitled to preliminary tests of not more than three sections of pipe covering each size, 12 to 72 in. in diameter, in which he is interested. The acceptability of 78- to 108-in. pipe shall be determined by tests of the quality of the concrete as placed in the pipe and by examination of the quality, amount, and accuracy of placement of the reinforcement. The strength of the concrete shall be determined from 6 by 12-in. test cylinders made from the concrete used in making the pipe and manufactured and cured under identical conditions with the pipe. Compression tests of such cylinders shall be made in accordance with the Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39) of the American Society for Testing Materials.[3] After these preliminary tests, a purchaser shall be entitled to additional tests in such num-

bers and at such times as he may deem necessary, provided that the total number of pipe tested shall not exceed 2 per cent[5] of the pipe delivered.

an order, and not to exceed five pieces of any one size; otherwise the number of pipe desired for testing shall be included in the order.

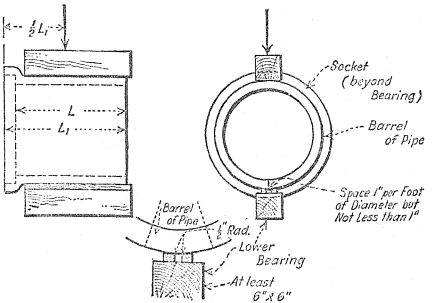

FIG. 2.—Three-Edge Bearings.

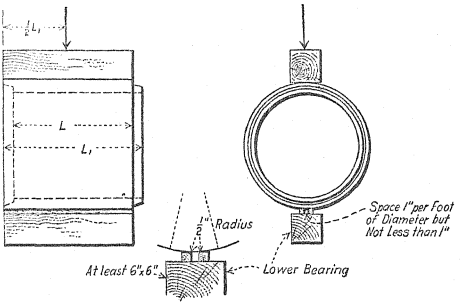

FIG. 3.—Three-Edge Bearings.

Tests for Occasional Orders

22. A purchaser who places occasional orders shall be entitled to test a number of pipe not to exceed 2 per cent[5] of an order, and not to exceed five pieces of any one size; otherwise the number of pipe desired for testing shall be included in the order.

[5] If these specifications are used for sewers, the number of pieces of pipe supplied for testing shall be in accordance with Section 20 of the Standard Specifications for Reinforced Concrete Sewer Pipe (A.S.T.M. Designation: C 75), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Crushing Strength Tests

23. Pipe may be tested for strength by either the three-edge-bearing method or the sand-bearing method, as described in Sections 25 and 26.

Apparatus

24. (*a*) In making the test, any me-

chanical or hand-power device may be used in which the head that applies the load moves at such a speed as to increase the load at a uniform rate of approximately 2000 lb. per linear foot of pipe per minute.

(*b*) It is necessary that the testing machine used for the strength tests shall produce a uniform deflection throughout the full length of the pipe. The testing machine shall be substantial and rigid throughout, so that the distribution of the load will not be affected appreciably by the deformation or yielding of any part.

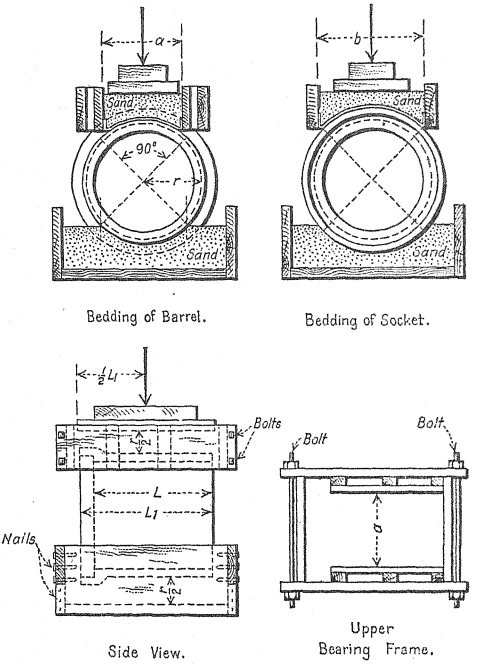

FIG. 4.—Sand Bearings.

(*c*) The load shall be applied continuously until the required strength of the pipe specified in Tables I and II is reached. The load per linear foot of pipe shall be calculated by dividing the total recorded load by the laying length. The pipe shall not be allowed to stand under

load longer than is required to apply the load and to observe and record it. The pipe shall be surface-dry when tested.

Three-Edge-Bearing Method

25. When the three-edge-bearing method is used (see Figs. 2 and 3), the ends of each specimen of pipe shall be accurately marked in halves of the circumference prior to the test. The lower bearings shall consist of two wooden strips with vertical sides having their interior top corners rounded to a radius of approximately $\frac{1}{2}$ in. The strips shall be straight and shall be securely fastened to a rigid base. The interior vertical sides of the strips shall be parallel and spaced a distance apart of 1 in. per foot of pipe diameter, but in no case less than 1 in. The upper bearing shall be a rigid wooden block, straight and true from end to end. The upper and lower bearings shall extend the full length of the pipe exclusive of the bell. The pipe shall be placed symmetrically between the two bearings as illustrated in Figs. 2 and 3. In testing pipe which is "out of line", the lines of the bearings chosen shall be from those which appear to give the most favorable conditions for fair test.

Sand-Bearing Method

26. (*a*) When the sand-bearing method is used (see Figs. 4 and 5), the ends of each specimen of pipe shall be accurately marked in quarters of the circumference prior to the test. Specimens shall be carefully bedded in sand, above and below, for one fourth the circumference of the pipe measured on the middle line of the barrel. The depth of bedding above and below the pipe at the thinnest points shall be one half the radius of the middle line of the barrel.

(*b*) The sand used shall be clean and shall contain not less than 5 per cent of moisture, and shall be such as will pass a 4760-micron (No. 4) sieve. The sand in the lower bearing shall be loose when the pipe is placed.

(*c*) The top bearing frame shall not be allowed to come in contact with the pipe nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck off level with a straightedge, and shall be covered with a rigid top bearing plate, the lower surface of which is a true plane, made of heavy timbers or other rigid material capable of distributing the test load uniformly without appreciable bending. The test load shall be applied at the exact center of this top bearing plate, or in such manner as to produce uniform deflection throughout the full length of the pipe. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used.

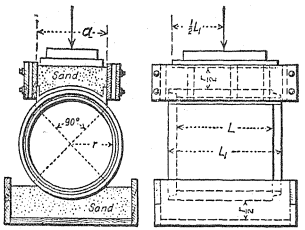

FIG. 5.—Sand Bearings.

(*d*) The test may be made without the use of a testing machine, by piling weights directly on a platform resting on the top bearing plate; provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the pipe, and that the platform shall not be allowed to touch the top bearing frame.

(*e*) The frames of the top and bottom bearings shall be made of timbers so

heavy as to avoid appreciable bending by the side pressure of the sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the pipe during the test. A strip of cloth may be attached, if desired, to the inside of the upper frame on each side, along the lower edge, to prevent the escape of sand between the frame and the pipe.

Acceptability and Retests

27. Pipe shall be acceptable under the strength tests when all test specimens conform to the test requirements. Should any of the preliminary test specimens provided for in Section 21, or any of the test specimens provided for in Section 22, fail to meet the test requirements, then the manufacturer will be allowed a retest on two additional specimens for each specimen that failed, and the pipe shall be acceptable only when all of these retest specimens meet the strength requirements.

Concrete Tests and Reinforcement Examination

28. By agreement between the purchaser and the manufacturer, the acceptability of all sizes of pipe may be determined by tests of the quality of concrete as placed in the pipe and the examination of the quality, amount, and accuracy of placement of the reinforcement. The strength of the concrete shall be determined as specified in Section 21.

Absorption Test

Absorption Test

29. Absorption tests shall be made in accordance with the procedure described in the following Paragraphs (*a*) to (*e*):

(*a*) *Test Specimens.*—The number of absorption test specimens shall be equal to the number of pipe provided for testing. The specimens shall be obtained from pipe that are acceptable as to strength, and shall be taken from pipe used in making the strength test after that test is made. The specimens shall be marked with the number or identification mark of the pipe from which they were taken. Each specimen shall have an area of 16 to 24 sq. in., as measured on one surface of the pipe, and a thickness equal to the full depth of the pipe shell, and shall be free from visible cracks.

(*b*) *Drying Specimens.*—Specimens shall be dried at a temperature not to exceed 230 F. (110 C.) until two successive weighings at intervals of not less than 2 hr. show an increment of loss not greater than 0.1 per cent of the original weight of the specimen.

(*c*) *Immersion and Reweighing.*—The dried specimens shall be placed in a suitable receptacle, covered with distilled water or rain water, raised to the boiling point and boiled for 5 hr., and then cooled in water to a final temperature of from 59 to 68 F. (15 to 20 C.). When cool, the specimens shall be removed from the water and allowed to drain for not more than 1 min. The superficial water shall then be removed by a towel or blotting paper, and the specimens immediately weighed.

(*d*) *Weighing Apparatus.*—The balance used shall be sensitive to 0.5 g. when loaded with 1 kg., and weighings shall be read at least to the nearest gram. When other than metric weights are used, the same degree of accuracy shall be obtained.

(*e*) *Calculations and Report.*—The increase in weight of the boiled specimen over its dry weight shall be taken as the absorption of the specimen, and shall be expressed as a percentage of the dry weight. The results shall be reported separately for each specimen.

Test Equipment

30. Every manufacturer furnishing pipe under these specifications shall furnish all facilities necessary to carry out the tests required in these specifications.

SIZES AND PERMISSIBLE VARIATIONS

Standard Sizes

31. Pipe of the internal diameters listed in Tables I and II shall be the standard sizes for culvert construction. In elliptical pipe, the inside diameter at the minor axis shall be equal to the iameter of the corresponding size of circular pipe.

Permissible Variations in Dimensions

32. (*a*) Variations of the internal diameter shall not exceed plus or minus 1 per cent for pipe having an internal diameter of 36 in. or less, and shall not exceed plus or minus 0.75 per cent for larger pipe. The shell thickness shall not be less than that intended in the design by more than 5 per cent at any point.

(*b*) Variations of the position of the reinforcement shall not exceed $\frac{1}{4}$ in. from the position provided in the design for pipe having an internal diameter of 48 in. or less, and shall not exceed $\frac{1}{2}$ in. for larger pipe; but the cover on the reinforcement shall not be less than $\frac{3}{4}$ in. at any point.

(*c*) The underrun in length of pipe from that specified shall be not more than $\frac{1}{8}$ in. per ft. with a maximum of $\frac{1}{2}$ in. in any length of pipe.

WORKMANSHIP AND FINISH

Finish

33. Pipe shall be substantially free from fractures, large or deep cracks, and surface roughness. The planes of the ends of the pipe shall be perpendicular to the longitudinal axis.

MARKING

Marking

34. The following shall be clearly stenciled on the pipe:

(*a*) The pipe class { by a "C" for Standard-Strength Pipe, and / by an "X-C" for Extra-Strength Pipe,

(*b*) The date of manufacture,

(*c*) The name or trade-mark of the manufacturer, and

(*d*) Elliptical pipe with circular reinforcing and circular pipe with elliptical reinforcing shall have the word "Top" or "Bottom" clearly stenciled on the inside of the pipe at the correct place to indicate the proper position when laid.

INSPECTION AND REJECTION

Age for Acceptance

35. Pipe shall be considered ready for acceptance when they conform to the requirements, as indicated by the specified tests.

Inspection

36. The quality of all materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by an inspector employed by the purchaser. The manufacturer, when so directed by the inspector, shall have holes cut in such sections of the finished pipe (not exceeding one hole in every 50 sections delivered), as desired, so that a proper inspection may be made of the quantity and placement of the reinforcement. If the pipe is also tested for strength or absorption, inspection of the reinforcement shall be made on the pipe sections used for those tests, and in no case shall the total number of pipe cut open for inspection of reinforcement exceed the number to which the purchaser is entitled under the provisions of Section 21, 22, or 27.

Rejection

37. Pipe shall be subject to rejection on account of failure to conform to any of the specification requirements or on account of any of the following:

(*a*) Fractures or cracks passing through the shell, except that a single end crack that does not exceed the depth of the joint shall not be cause for rejection. If a single end crack that does not exceed the depth of the joint exists in more than 10 per cent of the pipe inspected, however, the defective pipe shall be rejected.

(*b*) Defects that indicate imperfect mixing and molding.

(*c*) Surface defects indicating honeycombed or open texture.

(*d*) Spalls deeper than one half the depth of the joint or extending more than 4 in. around the circumference. If spalls not deeper than one half the depth of the joint or extending not more than 4 in. around the circumference exist in more than 10 per cent of the pipe, however, the defective pipe shall be rejected.

(*e*) Exposure of the circumferential reinforcement when such exposure would indicate that the reinforcement is misplaced.

(*f*) The complete absence of distinct web-like markings, which is indicative of a possible deficiency of water in the concrete mix, from the external surface of pipe made by any process in which the forms are removed immediately after the concrete has been placed.

Standard Specifications for
CONCRETE IRRIGATION PIPE[1]

A.S.T.M. Designation: C 118 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 118; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover concrete pipe intended to be used for the conveyance of irrigation water under low hydrostatic heads.

Class

2. Pipe manufactured according to these specifications shall be known as "A.S.T.M. Standard Concrete Irrigation Pipe."

Basis of Acceptance

3. The acceptability of the pipe shall be determined by the results of the tests prescribed in these specifications, if and when required, and by inspection to determine whether the pipe conforms to these specifications as to design and freedom from defects.

MATERIALS

Concrete

4. The concrete shall consist of portland cement, mineral aggregates and water.

Cement

5. Portland cement shall conform to requirements for type I or type III as prescribed in the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

Aggregates

6. Aggregates shall conform to the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33) of the American Society for Testing Materials.[3] The maximum size of coarse aggregate used shall not exceed one-third the shell thickness of the pipe.

Mixture

7. The aggregates shall be so graded and proportioned and thoroughly mixed with such proportions of cement and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of these specifications.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-13 on Concrete Pipe.

[2] Prior to adoption as standard, these specifications were published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

DESIGN AND PERMISSIBLE VARIATIONS IN DIMENSIONS

Alternate Designs

8. Manufacturers may submit to the purchaser, for approval, designs other than those in Table I. In no alternate design, however, shall the shell thickness and test requirements be less than those prescribed in Table I.

Variation in Diameter

9. Variation of the internal diameter shall not exceed plus or minus $\frac{3}{16}$ in. for 6-in. pipe, plus or minus $\frac{1}{4}$ in. for pipe having an internal diameter greater than 6 in. but not more than 18 in., and plus or minus $\frac{5}{16}$ in. for larger pipe.

TABLE I.—PHYSICAL TEST REQUIREMENTS FOR STANDARD CONCRETE IRRIGATION PIPE.

Internal Diameter, in.	Minimum Shell Thickness, in.	Test Requirements		
		Internal Hydrostatic Pressure on Individual Sections, psi.	Minimum Three-Edge-Bearing Load, lb. per linear ft.	Maximum Absorption, per cent
*6	$\frac{3}{4}$	75	1000	8
8	$\frac{7}{8}$	65	1000	8
10	1	60	1250	8
12	$1\frac{1}{8}$	55	1500	8
*14	$1\frac{1}{4}$	50	1600	8
15	$1\frac{3}{8}$	50	1700	8
*16	$1\frac{3}{8}$	50	1800	8
18	$1\frac{1}{2}$	50	1900	8
*20	$1\frac{5}{8}$	45	2000	8
21	2	45	2100	8
24	$2\frac{1}{8}$	40	2200	8

* Special sizes obtainable in some localities.

Variation in Thickness

10. The shell thickness at any point shall not be less than the minimum specified in Table I by more than $\frac{1}{16}$ in. for pipe having an internal diameter of 12 in. or less, $\frac{3}{32}$ in. for pipe having an internal diameter greater than 12 in. but not more than 18 in., and $\frac{1}{8}$ in. for larger pipe.

Joints

11. The ends of concrete irrigation pipe shall be so formed that when the pipe are laid together and the joints cemented they will make a continuous and uniform line of pipe with a smooth and regular interior surface. The joints shall be of such design as will permit effective cementing and placement without appreciable irregularities in the flow line.

PHYSICAL PROPERTIES AND TESTS

Test Specimens

12. (*a*) Specimens for tests shall be full-size pipe which shall in every respect conform to the inspection requirements prescribed in these specifications.

(*b*) The specimens to be tested shall be selected at random by the purchaser or his representative at the point or points specified in the order. The manufacturer shall furnish specimens for purpose of tests, without charge, up to 0.5 per cent of the number of pipe of each size included in the order, except that in no case shall less than two specimens be furnished, the manufacturer bearing all expense of testing such pipe. Should a larger number of specimens be tested upon demand of the purchaser or manufacturer, then the cost of such additional test specimens and the expense of testing shall be borne by the party making such demand.

(*c*) The purchaser shall specify the proportion of the test specimens that shall be subjected to the strength tests and the proportion that shall be subjected to the hydrostatic test.

(*d*) Should the test specimens selected by the purchaser conform to the test requirements, then all pipe represented by such specimens shall be accepted,

provided the pipe shall otherwise conform to the specifications.

(*e*) Should any of the specimens first tested fail to conform to the test requirements, then the manufacturer shall have the right to test two additional lengths of pipe from the same lot, selected by mutual agreement with the purchaser, for each specimen that has failed. If the additional pipe so tested all conform to the test requirements, then all pipe represented by such tests shall be accepted, otherwise they shall be subject to rejection.

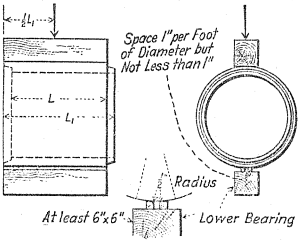

FIG. 1.—Three-Edge Bearings.

Strength Tests

13. Pipe shall be tested for strength by either the three-edge-bearing method or the sand-bearing method, as described in the following Paragraphs (*a*) to (*c*):

Three-Edge-Bearing Method

(*a*) When tested by the three-edge-bearing method (see Fig. 1), individual pipe shall meet the minimum load requirements specified in Table I.

In making the test the ends of each specimen of pipe shall be accurately marked in halves of the circumference prior to the test. The lower bearings shall consist of two wooden strips with vertical sides, having their interior top corners rounded to a radius of approximately $\frac{1}{2}$ in. The strips shall be straight and shall be securely fastened to a rigid block at least 6 by 6 in. in cross-section. The interior vertical sides of the strips shall be parallel and spaced a distance apart of 1 in. per foot of pipe diameter, but in no case less than 1 in. If requested by the manufacturer or the purchaser previous to the test, before the pipe is placed, a fillet of plaster of Paris and sand, thick enough to compensate for the inequalities of the pipe barrel, shall be cast on and between the lower bearings. The pipe shall be placed upon the fillet while the plaster of Paris is still somewhat plastic. The

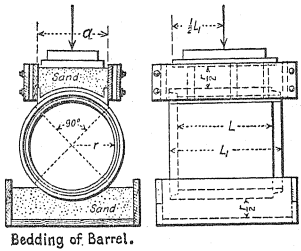

FIG. 2.—Sand Bearings.

upper bearing shall be a rigid wooden block at least 6 by 6 in. in cross-section, straight and true from end to end. A fillet of plaster of Paris may also be cast along the length of the crown of the pipe to equalize the bearing. The upper bearing shall be brought in contact while the plaster of Paris is still somewhat plastic. The upper and lower bearings shall extend the full length of the pipe (see Fig 1).

Sand-Bearing Method

(*b*) When tested by the sand-bearing method (see Fig. 2) individual pipe shall meet a minimum load 50 per cent greater

than specified in Table I for the three-edge-bearing test.

When the sand-bearing method (see Fig. 2) is used the ends of each specimen of pipe shall be accurately marked in quarters of the circumference prior to the test. Specimens shall be carefully bedded in sand, above and below, for one-fourth the circumference of the pipe measured on the middle line of the barrel. The depth of the bedding above and below the pipe at the thinnest points shall be one-half the radius of the middle line of the barrel.

The sand used shall be clean and shall contain not less than 5 per cent of moisture, and shall be such as will pass a 4760-micron (No. 4) sieve. The sand in the lower bearing shall be loose when the pipe is placed.

The top bearing frame shall not be allowed to come in contact with the pipe nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck off level with a straightedge, and shall be covered with a rigid top-bearing plate, the lower surface of which is a true plane, made of heavy timbers or other rigid material capable of distributing the test load uniformly without appreciable bending. The test load shall be applied at the exact center of this top bearing plate, or in such manner as to produce uniform deflection throughout the full length of the pipe. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used.

The test may be made without the use of a testing machine, by piling weights directly on a platform resting on the top bearing plate; provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the pipe, and that the platform shall not be allowed to touch the top bearing frame.

The frames of the top and bottom bearings shall be made of timbers so heavy as to avoid appreciable bending by the side pressure of sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the pipe during the test. A strip of cloth may be attached, if desired, to the inside of the upper frame on each side, along the lower edge, to prevent the escape of sand between the frame and the pipe.

Testing Apparatus

(*c*) In making the test, any mechanical or hand-power device may be used in which the head that applies the load moves at such a speed as to increase the load at a uniform rate of approximately 2000 lb. per linear foot of pipe per minute.

It is necessary that the testing machine used for the strength tests shall produce a uniform deflection throughout the full length of the pipe. The testing machine shall be substantial and rigid throughout, so that the distribution of the load will not be affected appreciably by the deformation or yielding of any part.

The load shall be applied continuously until the required strength of the pipe specified in Table I is reached. The load per linear foot of pipe shall be calculated by dividing the total recorded load by the laying length. The pipe shall not be allowed to stand under load longer than is required to apply the load and to observe and record it. The pipe shall be surface-dry when tested.

Hydrostatic Test

14. (*a*) When an individual pipe is subjected to the internal hydrostatic pressure given in Table I, there shall be no leakage through the shell of the pipe. Moisture appearing on the surface of the pipe in the form of patches or beads

adhering to the surface shall not be considered leakage.

(*b*) The equipment for making the hydrostatic test shall be mutually satisfactory to the purchaser and the manufacturer. Suitable fittings shall be provided for exhausting the air and admitting the water into the specimen. A standardized pressure gage for recording the internal pressure shall be connected close to the specimen. The pressure shall first be increased uniformly to 10 psi. and held at this pressure for 10 min. The water pressure shall then be increased uniformly until the required maximum pressure is reached as specified in Table I. If the pipe is to be coated on the inside with cement grout or other material, the hydrostatic test shall be made before such coating is applied.

Absorption Test

15. Absorption tests shall be made in accordance with the procedure described in the following Paragraphs (*a*) to (*e*):

(*a*) *Test Specimens.*—The number of absorption test specimens shall be equal to the number of pipe provided for testing. The specimens shall be obtained from pipe that are acceptable as to strength, and shall be taken from pipe used in making the strength test after that test is made. The specimens shall be marked with the number or identification mark of the pipe from which they were taken. Each specimen shall have an area of 12 to 20 sq. in., as measured on one surface of the pipe, and a thickness equal to the full depth of the pipe shell, and shall be free from visible cracks.

(*b*) *Drying Specimens.*—Specimens shall be dried at a temperature not to exceed 230 F. (110 C.) until two successive weighings at intervals of not less than 2 hr. show an increment of loss not greater than 0.1 per cent of the original weight of the specimen.

(*c*) *Immersion and Reweighing.*—The dried specimens shall be placed in a suitable receptacle covered with distilled water or rain water, raised to the boiling point and boiled for 5 hr., and then cooled in water to a final temperature of from 59 to 68 F. (15 to 20 C.). When cool, the specimens shall be removed from the water and allowed to drain for not more than 1 min. The superficial water shall then be removed by a towel or blotting paper, and the specimens immediately weighed.

(*d*) *Weighing Apparatus.*—The balance used shall be sensitive to 0.5 g. when loaded with 1 kg., and weighings shall be read at least to the nearest gram. When other than metric weights are used, the same degree of accuracy shall be obtained.

(*e*) *Calculations and Report.*—The increase in weight of the boiled specimen over its dry weight shall be taken as the absorption of the specimen, and shall be expressed as a percentage of the dry weight. The results shall be reported separately for each specimen.

WORKMANSHIP AND FINISH

Finish

16. Pipe shall be concentric, and free from fractures, large or deep cracks and surface roughness, other than those normally produced in the manufacture of the pipe. The planes of the ends of the pipe shall be perpendicular to the longitudinal axis.

INSPECTION AND REJECTION

Age for Shipment

17. Pipe shall be considered ready for acceptance when they conform to the test requirements prescribed in these specifications, and have been properly cured for at least 7 days.

Inspection

18. The quality of all materials and the finished pipe shall be subject to inspection and approval by an inspector employed by the purchaser.

Rejection

19. Pipe shall be subject to rejection on account of failure to conform to any of the specification requirements or on account of any of the following:

(*a*) Fractures or cracks passing through the shell, except that an end crack that does not exceed the depth of the joint, or a fracture that at its deepest point does not exceed the depth of the joint nor extend more than 10 per cent around the circumference of the joint shall not be considered cause for rejection unless these defects exist in more than 5 per cent of the pipe inspected. If these defects exist in more than 5 per cent of the pipe inspected, the defective pipe shall be rejected.

(*b*) Defects which indicate imperfect mixing, placing, and curing of concrete.

(*c*) The absence of distinct web-like markings on the external surface of pipe made by the packerhead or machine-tamped process.

Recommended Practice For

LAYING SEWER PIPE[1]

A.S.T.M. Designation: C 12 – 19

ADOPTED, 1919.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 12; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Preparation of Trenches for Pipe Laying

1. (*a*) Pipe lines should be placed at a sufficient depth below the surface of the street to avoid dangerous pressure or impact. When this is not possible, special reinforcement should be provided.

(*b*) Trenches should be only of sufficient width to provide a free working space on each side of the pipe, preferably of not over one-third of the nominal diameter and never less than 4 in., according to the size of the pipe and the character of the ground; but in every case there should be sufficient space between the pipe and the sides of the trench to make it possible to thoroughly ram the back-filling around the pipe and to secure tight joints.

(*c*) Trenches should be kept free from water until the material in the joints and masonry has sufficiently hardened.

(*d*) To protect pipe lines from unusual stresses, all work should preferably be done in open trenches.

Preparation of Foundations for Pipe Laying

2. (*a*) The foundations in the trench should be formed to prevent any subsequent settlement which might result in excessive pressure and consequent rupture of the pipes.

(*b*) If the foundation is rock, an equalizing bed of concrete or sand well compacted should be placed upon the rock. The thickness of these beds should be not less than 4 in. Pipes should be laid in these beds so that at least the lower third of each pipe is supported throughout its entire length.

(*c*) If the foundation is good firm earth, the earth should be pared or molded to give a full support to the lower third of each pipe and, if necessary to secure a proper bearing for the pipe, a layer of concrete, fine gravel, or other suitable material should be placed. The same means of securing a firm foundation should be adopted in case the excavation has been made deeper than necessary.

[1] Under the standardization procedure of the Society, this recommended practice was formerly under the jurisdiction of the Committee on Clay and Concrete Pipe. In 1932 that committee was divided into two committees, C-4 on Clay Pipe and C-13 on Concrete Pipe, and in October, 1933, this recommended practice was placed under the jurisdiction of Committee C-4 with the understanding that it would be suitably revised to apply to clay pipe only.

[2] Prior to adoption as standard, this recommended practice was published as tentative from 1915 to 1919, being revised in 1916 and 1917.

(*d*) If there is no good natural foundation, the pipes should be laid in a concrete cradle supported on a masonry foundation carried to a soil of satisfactory bearing power, or supported on a structure designed to carry the weight of pipe and its load to a firm bearing.

Pipe Laying

3. (*a*) The laying of pipes in finished trenches should be commenced at the lowest point, so that the spigot ends point in the direction of flow.

(*b*) All pipes should be laid with ends abutting and true to line and grade. They should be fitted and matched so that when laid in the work they will form a sewer with a smooth and uniform invert. It is necessary to use all possible care when shoving the pipes together, so that the joints will not be unnecessarily large.

(*c*) Sockets should be carefully cleaned before pipes are lowered into trenches. The pipes should be so lowered as to avoid unnecessary handling in the trench.

(*d*) The pipes should be set firmly according to line and grade, and the joints carefully adjusted and filled with the jointing material.

(*e*) Joints should be made in the following manner: A closely twisted hemp or oakum gasket of suitable diameter, in no case less than $\frac{3}{4}$ in., and in one piece of sufficient length to pass around the pipe and lap at the top, should be solidly rammed into the annular spaces between the pipes with a suitable calking tool. When cement joints are used, the gasket should first be saturated with neat cement grout. The remainder of the space should then be completely filled with the jointing materials.

Backfilling Trenches

4. (*a*) All trenches and excavations should be backfilled immediately after the pipes are laid therein, unless other protection of the pipe line is directed. The backfilling material should be selected and deposited with special reference to the future safety of the pipes. Clean earth, sand, or rock dust should be solidly tamped about the pipes up to a level at least 2 ft. above the top of the pipes. This material should be carefully deposited in uniform layers. Unless otherwise permitted, each layer should be carefully and solidly tamped or rammed with proper tools so as not to injure or disturb the pipe line.

(*b*) Puddling or water flooding for consolidating the backfilling is recommended only for sandy and gravely materials. If this method is used, the first flooding should be applied after the backfilling has been compacted by tamping up to 2 ft. above the top of the pipes, and the second flooding during or after the subsequent filling of the trench. An excess of water should be avoided, in order to prevent disturbance of the earth under and around the pipes and also to prevent an undue excess of pressure upon them.

(*c*) Walking or working on the completed pipe line, except as may be necessary in tamping or backfilling, should not be permitted until the trench has been backfilled to a height of at least 2 ft. over the top of the pipes.

(*d*) The filling of the trench should be carried on simultaneously on both sides of the pipes, in such a manner that injurious side pressures do not occur.

Standard Specifications for

CONCRETE AGGREGATES[1]

A.S.T.M. Designation: C 33 – 44

ADOPTED, 1939; REVISED, 1940, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 33; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover fine and coarse aggregates suitable for use in concrete.

NOTE: *Quality of Aggregates.*—It is recognized that for certain purposes satisfactory results may be obtained with materials not conforming to these specifications. In such cases the use of fine and coarse aggregates not conforming to these specifications may be authorized only under special provisions based upon laboratory studies of the possibility of designing a mixture of materials to be used on the job that will yield concrete equivalent in quality to the specified mixture made with material complying with these specifications in all respects.

FINE AGGREGATE

General Characteristics

2. Fine aggregate shall consist of natural sand or of sand prepared from stone, blast-furnace slag, or gravel, or, subject to the approval of the engineer, other inert materials having similar characteristics.

Deleterious Substances

3. (*a*) The amount of deleterious substances in fine aggregate shall not exceed the limits prescribed in Table I.

TABLE I.—PERMISSIBLE LIMITS FOR DELETERIOUS SUBSTANCES IN CONCRETE AGGREGATES.

	Recommended Permissible Limits, max., per cent by weight	Maximum Permissible Limits, per cent by weight
Clay lumps	1	1.5
Coal and lignite	0.25	1
Material finer than No. 200 sieve:		
(*a*) In concrete subject to surface abrasion	2	4
(*b*) All other classes of concrete	3	5
Other deleterious substances (such as shale, alkali, mica, coated grains, soft and flaky particles)	as specified	as specified

NOTE.—The recommended limits should be specified on all work where it is economically practicable to obtain materials conforming thereto.

(*b*) *Organic Impurities.*—All fine aggregate shall be free from injurious amounts of organic impurities. Aggregates subjected to the colorimetric test for organic impurities and producing a color darker than the standard shall be

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, these specifications were published as tentative from 1921 to 1939, being revised in 1923, 1926, 1928, 1930, 1931, 1936, and 1937.

rejected unless they pass the mortar strength test as specified in Section 5.

Grading

4. (*a*) Fine aggregate shall be well graded from coarse to fine and when tested by means of laboratory sieves shall conform to the following requirements:

Sieve[3]	Percentage Passing
⅜-in.	100
No. 4 (4760-micron)	95 to 100
No. 16 (1190-micron)	45 to 80
No. 50 (297-micron)	10 to 30
No. 100 (149-micron)	2 to 10

NOTE 1.—At the approval of the engineer, when the fine aggregate is to be used in concrete mixtures containing five or more sacks of cement per cubic yard, the limitations on the material passing the No. 50 and No. 100 sieves may be 5 to 30 and 0 to 10 per cent, respectively.

NOTE 2.—Fine aggregate failing to pass the minimum requirements for the material passing the No. 50 or No. 100 sieve, or both, may be used, provided a satisfactory inorganic fine material is added to correct for the difference in grading.

NOTE 3.—Attention is called to the fact that the relatively wide range in grading which is shown in the above table should be permitted only when it is economically impracticable to obtain materials meeting more restrictive requirements. The most desirable grading will depend upon the type of work and the class of concrete. For the leaner mixes, or when a small size coarse aggregate is used, in cases where the degree of workability is important, it is desirable to further restrict the allowable ranges in sizes shown so as to insure a grading approaching the maximum percentage passing each sieve. On the other hand, for the richer mixes, in the interests of maximum strength and economy, a grading as coarse as is consistent with the requirements for workability should be specified. However, in no case should a range in grading be required more restrictive on any one sieve than indicated below:

No. 16 (1190-micron) sieve	20 per cent
No. 50 (297-micron) sieve	15 per cent
No. 100 (149-micron) sieve	5 per cent

(*b*) *Uniformity of Grading.*—The above gradation for fine aggregate represents the extreme limits which shall determine the suitability for use of fine aggregate from all sources of supply. The gradation of fine aggregate from any one source shall be reasonably uniform and not subject to the extreme percentages of gradation specified above. For the purpose of determining the degree of uniformity of a fine aggregate, a fineness modulus determination shall be made upon representative samples of fine aggregate from such sources as are proposed for use. Fine aggregate from any one source having a variation in fineness modulus greater than plus or minus 0.20 from the fineness modulus of the representative sample submitted by the contractor shall either be rejected or may be accepted subject to such adjustment in proportions as may be necessary by reason of changes in grading of fine aggregate. Fine aggregate from different sources of supply shall not be mixed or stored in the same pile nor used alternately in the same class of construction or mix, without permission from the engineer.

(*c*) In case the concrete resulting from a mixture of aggregates approaching the extreme limits for gradation is not of a workable character or when finished does not exhibit a proper surface, due to an excess of particles approximately ⅜ to ½ in. in size, either a fine aggregate having a sufficiently greater percentage of fine material, or a coarse aggregate having a sufficiently smaller percentage of fine material shall be used.

Mortar Strength

5. Fine aggregate shall be of such quality that when made into a mortar and subjected to the mortar strength test (Section 11 (*e*)) it shall develop a compressive strength at 7 and 28 days of not less than .... per cent[4] of that developed by a mortar prepared in the same manner with the same cement and graded standard sand having a fineness modulus of 2.40 ± 0.10.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] A percentage should be inserted by the engineer to suit local conditions.

NOTE.—The graded standard sand mentioned in Section 5 may be obtained with a mixture of approximately equal parts by weight of standard Ottawa sand conforming to the requirements prescribed in the Standard Method of Test for Tensile Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 190)[5] and graded Ottawa sand conforming to the requirements specified in Section 4 of the Standard Method of Test for Compressive Strength of Hydraulic-Cement Mortars (A. S. T. M. Designation: C 109).[5]

Soundness

6. Fine aggregate shall pass a sodium or magnesium sulfate accelerated soundness test, except that aggregates failing in the accelerated soundness test may be used if they pass a satisfactory freezing-and-thawing test.

COARSE AGGREGATE

General Characteristics

7. Coarse aggregate shall consist of crushed stone, gravel, blast-furnace slag, or other approved inert materials of similar characteristics, or combinations thereof, having hard, strong, durable pieces, free from adherent coatings and conforming to the requirements of these specifications.

Deleterious Substances

8. The amount of deleterious substances in coarse aggregate shall not exceed the following limits:

	Recommended[a] Permissible Limits, max., per cent by weight	Maximum Permissible Limits, per cent by weight
Soft fragments	2	5
Coal and lignite	0.25	1
Clay lumps	0.25	0.25
Material finer than No. 200 (74-micron) sieve	0.5[b]	1[b]
Other deleterious substances	as specified	as specified

[a] The recommended requirements should be specified on all work where it is economically practicable to obtain materials conforming thereto.

[b] When the material finer than the No. 200 sieve consists essentially of crusher dust, the recommended and maximum permissible limits specified above may be raised to 0.75 and 1.5 per cent, respectively.

[5] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Grading

9. (*a*) Coarse aggregate shall be well graded between the limits specified and shall conform to the requirements prescribed in Table II.

(*b*) Designation of a given coarse aggregate as aggregate of a certain maximum size shall be understood to mean that more than 5 per cent must be retained on the next smaller of the sieves appearing in Table II.

(*c*) In case the concrete resulting from a mixture of aggregates approaching the extreme limits for gradation is not a workable character or when finished does not exhibit a proper surface, due to an excess of particles approximately ¼ to ½ in. in size, either a fine aggregate having a sufficiently greater percentage of fine material or a coarse aggregate having a sufficiently smaller percentage of fine material shall be used.

Weight of Slag

10. Blast-furnace slag that meets the grading requirements of these specifications shall conform to the following weight requirements:

	Compact Weight, min., lb. per cu. ft.
General concrete	65
Concrete subject to abrasion	70

Soundness

11. Coarse aggregate shall pass a sodium or magnesium sulfate accelerated soundness test, except that aggregates failing in the accelerated soundness test may be used if they pass a satisfactory freezing-and-thawing test.

NOTE.—Many engineers believe that an abrasion test for coarse aggregate to be used in concrete subject to abrasion is important, but no test limits are specified, due to the status of knowledge concerning suitable specification limits for this test. The committee believes that the abrasion tests when applied to blast-furnace slag do not meet the requirements for a desirable test. This recommendation is made after consideration of the results of a study to

determine the value of the abrasion test as to the concrete making properties of slag.

Methods of Sampling and Testing

12. The aggregates shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials (except as specified in Paragraph (*j*)):

(*a*) *Sampling.*—Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75).[5]

(*f*) *Compressive Strength.*—Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39).[5]

(*g*) *Soundness.*—Tentative Method of Test for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate (A.S.T.M. Designation: C 88).[5]

(*h*) *Clay Lumps.*—Standard Method of Test for Clay Lumps in Aggregates (A.S.T.M. Designation: C 142).[5]

(*i*) *Coal and Lignite.*—Standard Method of Test for Coal and Lignite in Sand (A.S.T.M. Designation: C 123).[5]

(*j*) *Shale.*—Method of Test for Per-

TABLE II.—GRADING REQUIREMENTS FOR CRUSHED STONE, GRAVEL, AND BLAST-FURNACE SLAG.

Designated Size	Percentages Passing Laboratory Sieves Having Square Openings[a]							
	2½ in.	2 in.	1½ in.	1 in.	¾ in.	½ in.	⅜ in.	No. 4 (4760-micron)

2 in. to 1 in.	100	90 to 100	35 to 70	0 to 15	.....	.....	.....	.....
1½ in. to ¾ in.	...	100	90 to 100	20 to 55	0 to 15	.....	.....	.....

[a] Not more than 5 per cent passing the No. 8 (2380-micron) sieve.

(*b*) *Sieve Analysis.* — Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[5]

(*c*) *Amount of Material Finer than No. 200 Sieve.*—Standard Method of Test for Amount of Material Finer than No. 200 Sieve in Aggregates (A.S.T.M. Designation: C 117).[5]

(*d*) *Organic Impurities.*—Standard Method of Test for Organic Impurities in Sands for Concrete (A.S.T.M. Designation: C 40).[5]

(*e*) *Mortar Strength.* — Standard Method of Test for Structural Strength of Fine Aggregate Using Constant Water-Cement-Ratio Mortar (A.S.T.M. Designation: C 87).[5]

centage of Shale in Aggregate,[6] Standard Method T-10 of The American Association of State Highway Officials.

(*k*) *Moisture.*—Tentative Method of Test for Surface Moisture in Fine Aggregate (A.S.T.M. Designation: C 70).[5]

(*l*) *Weight of Slag.*—Standard Method of Test for Unit Weight of Aggregate (A.S.T.M. Designation: C 29).[5]

(*m*) *Abrasion.*—If abrasion tests are made the following methods of test are recommended:

(1) *Abrasion of Gravel.*—Tentative Method of Test for Abrasion of Gravel by Use of the Deval Machine (A.S.T.M. Designation: D 289).[5]

(2) *Abrasion of Rock.*—Standard Meth-

[6] See "Standard Specifications for Highway Materials and Methods of Sampling and Testing," the Am. Assn. State Highway Officials, Part II, p. 201 (1942).

od of Test for Abrasion of Rock by Use of the Deval Machine (A.S. T.M. Designation: D 2),[5] except that for material having specific gravities lower than 2.2 a 4000-g. sample shall be used.

(*n*) *Fineness Modulus.*—The fineness modulus is the sum of percentages in the sieve analysis divided by 100 when the sieve analysis is expressed as cumulative percentages coarser than each of the following sieves: No. 100 (149-micron), No. 50 (297-micron), No. 30 (590-micron), No. 16 (1190-micron), No. 8 (2380-micron), and No. 4 (4760-micron). The sieve analysis shall be made in accordance with Standard Method C 136.[5]

Standard Specifications for

LIGHTWEIGHT AGGREGATES FOR CONCRETE[1]

A.S.T.M. Designation: C 130 - 42

ADOPTED, 1939; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 130; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover lightweight aggregates suitable for use in concrete.

NOTE.—The specification limits that are not enclosed in parentheses are recommended for use when it is practicable to secure economically materials conforming to them. When it is not practicable to secure such materials economically the specification limits may be extended, but not beyond the maximum permissible limits shown in parentheses. Generally, such extension in the specification limits can be compensated for by a change in the design of the mix or by the exercise of more than the usual care in the control of the concrete during construction.

General Characteristics

2. (*a*) Lightweight aggregates shall consist of pumice, lava, tufa, slag, burned clay, burned shale, cinders derived from the high-temperature combustion of coal or coke showing a loss on ignition of not more than 25 per cent (40 per cent)[3] and volatile matter of not more than 5 per cent, or, subject to approval by the engineer, other material having strong, durable particles and conforming to the requirements of these specifications.

(*b*) When approved by the engineer, for the purpose of securing the desired workability, lightweight aggregate meeting the requirements of these specifications may be mixed with a fine aggregate meeting the requirements of the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33) of the American Society for Testing Materials,[4] provided, however, that the combined aggregate shall conform to all the other requirements of these specifications.

Deleterious Substances

3. (*a*) Lightweight aggregate shall not contain excessive amounts of deleterious substances.

(*b*) *Organic Impurities.*—All lightweight aggregate shall be free from injurious amounts of organic impurities. Aggregates subjected to the colorimetric

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, these specifications were published as tentative from 1937 to 1939.

[3] See Note under Section 1.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

test for organic impurities and producing a color darker than the standard shall be rejected unless they pass the mortar strength test (Section 6), which requirement may be raised by the engineer by not more than 10 per cent.

Grading

4. Lightweight aggregate shall be graded from coarse to fine within the limits prescribed in Table I.

Unit Weight

5. Lightweight aggregate meeting the grading requirements of these specifications when tested in a dry condition shall conform to the following weight requirements:

	Unit Weight, max., lb. per cu. ft.
Fine aggregate	75
Coarse aggregate	55

Mortar Strength

6. (*a*) Lightweight aggregate shall be of such quality that when made into a mortar and subjected to the mortar strength test (Section 8 (*d*)) it shall develop a compressive strength at 7 or 28 days of not less than 70 per cent (or, for concrete not exposed to wear or weather, 60 per cent) of that developed by a mortar prepared in the same manner with the same cement and the graded standard sand described in Paragraph (*b*). Coarse aggregate shall be reduced to the grading specified for fine aggregate before use in the mortar test.

(*b*) The standard sand (Note) referred to in Paragraph (*a*) shall be natural silica sand from Ottawa, Ill., graded as follows:

Sieves[5]	Percentage Retained
No. 100 (149-micron)	98 ± 2
No. 50 (297-micron)	72 ± 5
No. 30 (590-micron)	2 ± 2
No. 16 (1190-micron)	none

NOTE.—Sand conforming to the above requirements may be obtained from the Ottawa Silica Co., Ottawa, Ill.

TABLE I.—GRADING REQUIREMENTS FOR LIGHTWEIGHT AGGREGATES.

Size Designation	Percentages Passing Sieves Having Square Openings[5]								
	1 in.	¾ in.	½ in.	⅜ in.	No. 4 (4760 micron)	No. 8 (2380 micron)	No. 16 (1190 micron)	No. 50 (297 micron)	No. 100 (149 micron)
Fine Aggregate:									
¼ in. to dust	....	.....	.....	100	95 to 100	.....	45 to 80	10 to 30	5 to 15
⅜ in. to dust	....	.....	100	95 to 100	55 to 80	.....	.....	10 to 25	5 to 15
Coarse Aggregate:									
½ in. to No. 4	....	100	90 to 100	40 to 75	0 to 15	0 to 5	.....	.....	.....
½ in. to No. 8	....	.....	100	85 to 100	0 to 20	0 to 5	.....	.....	.....
¾ in. to No. 4	100	90 to 100	.....	20 to 55	0 to 10	0 to 5	.....	.....	.....

Soundness

7. Lightweight aggregate, when subjected to five cycles of the accelerated sulfate soundness test, shall lose not more than 12 per cent (15 per cent)[8] in weight, provided, however, that an aggregate failing in this requirement may be accepted if it passes a satisfactory freezing-and-thawing test. The engineer may waive the soundness test requirement for lightweight aggregate for concrete not to be exposed to moisture.

Methods of Sampling and Testing

8. Lightweight aggregate shall be sampled and the properties enumerated

[5] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75).[4]

(*b*) *Grading.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[4]

(*c*) *Unit Weight.*—Standard Method of Test for Unit Weight of Aggregate (A.S.T.M. Designation: C 29),[4] utilizing the jigging procedure described in Section 6 of Methods C 29. Unit weights shall be determined on material dried to constant weights at not less than 100 C. and not more than 120 C.

(*d*) *Mortar Strength.*—Standard Method of Test for Structural Strength of Fine Aggregate Using Constant Water-Cement-Ratio Mortar (A.S.T.M. Designation: C 87).[4]

(*e*) *Compressive Strength.*—Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39).[4]

(*f*) *Soundness.*—Tentative Method of Test for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate (A.S.T.M. Designation: C 88).[4]

(*g*) *Organic Impurities.*—Standard Method of Test for Organic Impurities in Sands for Concrete (A.S.T.M. Designation: C 40).[4]

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.7-1944
AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 96-44

Standard Method of Test for

ABRASION OF COARSE AGGREGATE BY USE OF THE LOS ANGELES MACHINE[1]

A.S.T.M. Designation: C 131 – 44

ADOPTED, 1939; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 131; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for testing crushed rock, crushed slag, uncrushed gravel, and crushed gravel (Note), for resistance to abrasion in the Los Angeles testing machine with an abrasive charge.

NOTE.—Ledge rock, hand-broken into approximately cubical fragments of the different sizes shown, when tested by this method, has been found to have a loss of approximately 85 per cent of that for crushed rock of the same quality

Apparatus

2 (*a*) *Los Angeles Machine.*—The Los Angeles abrasion testing machine, conforming in all its essential characteristics to the design shown in Fig. 1, shall be used. The machine shall consist of a hollow steel cylinder, closed at both ends, having an inside diameter of 28 in. and an inside length of 20 in. The cylinder shall be mounted on stub shafts attached to the ends of the cylinder but not entering it, and shall be mounted in such a manner that it may be rotated about its axis in a horizontal position. An opening in the cylinder shall be provided for the introduction of the test sample. The opening shall be closed dust-tight with a removable cover bolted in place. The cover shall be so designed as to maintain the cylindrical contour of the interior surface unless the shelf is so located that the charge will not fall on the cover, or come in contact with it during the test. A removable steel shelf, projecting radially 3½ in. into the cylinder and extending its full length, shall be mounted along one element of the interior surface of the cylinder. The shelf shall be of such thickness and so mounted, by bolts or other approved means, as to be firm and rigid. The position of the shelf shall be such that the distance from the shelf to the opening, measured along the circumference of the cylinder in the direction of rotation, shall not be less than 50 in.

NOTE.—The use of a shelf of wear-resistant steel, rectangular in cross-section and mounted independently of the cover, is preferred. How-

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1937 to 1939, being revised in 1938 and 1939.

ever, a shelf consisting of a section of rolled angle, properly mounted on the inside of the cover plate, may be used provided the direction of rotation is such that the charge will be caught on the outside face of the angle.

(*b*) *Sieves.*—Square-hole sieves of the following sizes shall conform to the

Abrasive Charge

3. (*a*) The abrasive charge shall consist of cast-iron spheres or steel spheres approximately $1\frac{7}{8}$ in. in diameter and each weighing between 390 and 445 g. The cast-iron spheres shall conform to

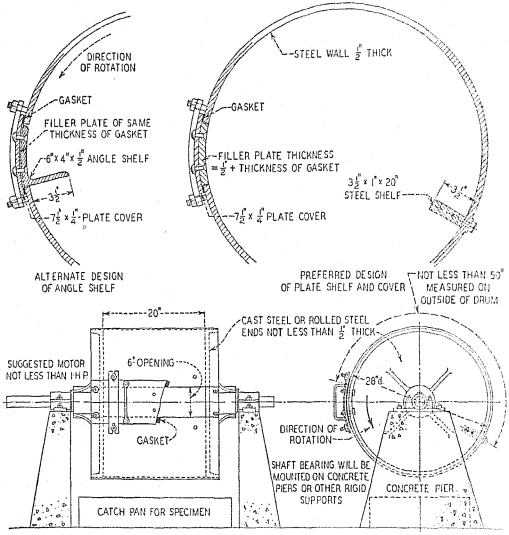

FIG. 1.—Los Angeles Abrasion Testing Machine.

Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials:[3]

Fine Series:
No. 12 (1680-micron)
Coarse Series:
$1\frac{1}{2}$-in.
1-in.
$\frac{3}{4}$-in.
$\frac{1}{2}$-in.
$\frac{3}{8}$-in.

the following requirements as to chemical composition:

Combined carbon, min., per cent	2.50
Graphitic carbon, max., per cent	0.25
Manganese, max., per cent	0.50
Phosphorus, max., per cent	0.25
Sulfur, max., per cent	0.08
Silicon, per cent	1.00

NOTE.—Cast-iron spheres, uniform in size, conforming to these specifications are available. The above chemical requirements for the cast-iron spheres are identical with those for the cast-iron spheres used in the rattler test for paving brick as prescribed in the Standard Specifications for Paving Brick (A.S.T.M. Designa-

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

tion: C 7) of the American Society for Testing Materials.[3]

Steel spheres 1 37/32 in. in diameter and weighing 417 g. can be obtained from at least one manufacturer. If they are not readily available, the next larger size (1 1/8 in.) may be ground to size.

(*b*) The abrasive charge, depending upon the grading of the test sample as described in Section 4, shall be as follows:

Grading	Number of Spheres	Weight of Charge, g.
A	12	5000 ± 25
B	11	4584 ± 25
C	8	3330 ± 20
D	6	2500 ± 15

Test Sample

4. The test sample shall consist of 5000 g. of clean, dry aggregate and shall conform to one of the gradings shown in Table I. The grading used shall be that most nearly representing the aggregate furnished for the work.

TABLE I.—GRADINGS OF TEST SAMPLES.

Sieve Size (Square Openings)		Weight, g.			
Passing	Retained on	Grading A	Grading B	Grading C	Grading D
1½ in.	1 in.	1250	....	....	....
1 in.	¾ in.	1250	....	....	....
¾ in.	½ in.	1250	2500	....	....
½ in.	⅜ in.	1250	2500	....	....
⅜ in.	No. 3	....	....	2500	....
No. 3	No. 4	....	....	2500	....
No. 4	No. 8	....	....	....	5000

Procedure

5. The test sample and the abrasive charge shall be placed in the Los Angeles abrasion testing machine and the machine rotated for 500 revolutions at a speed of from 30 to 33 r.p.m. If an angle is used as the shelf, the machine shall be rotated in such a direction that the charge is caught on the outside surface of the angle. At the completion of the test, the material shall be removed from the machine and sieved on a No. 12 (1680-micron) sieve. The material retained on the sieve shall be washed, dried, and accurately weighed to the nearest gram (Note).

NOTE.—Attention is called to the fact that valuable information concerning the uniformity of the sample under test may be obtained by determining the loss after 100 revolutions. When this determination is made, care should be taken to avoid loss of any part of the sample; the entire sample, including the dust of abrasion, shall be returned to the testing machine for the completion of the test.

Calculation

6. The difference between the original weight and the final weight of the test sample shall be expressed as a percentage of the original weight of the test sample. This value shall be reported as the percentage of wear.

Standard Method of Test for
CLAY LUMPS IN AGGREGATES[1]

A.S.T.M. Designation: C 142 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 142; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for the approximate determination of clay lumps in the routine examination of aggregates.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—Balance or scale sensitive to within 0.1 per cent of the weight of the sample to be weighed.

(*b*) *Containers.*—Containers of a size and shape that will permit the spreading of the sample on the bottom in a thin layer.

(*c*) *Sieves.*—Sieves conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

Samples

3. (*a*) Samples shall be obtained by quartering or by the use of a sampler from a representative sample selected from the material to be tested. They shall be handled in such a manner as to avoid breaking up clay lumps which may be present.

(*b*) Samples shall be dried to substantially constant weight at a temperature not exceeding 110 C. (230 F.).

(*c*) Samples of fine aggregate shall consist of the particles coarser than a No. 16 (1190-micron) sieve and shall weigh not less than 100 g.

(*d*) Samples of coarse aggregate shall be separated into different sizes using the following sieves: No. 4 (4760-micron), $\frac{3}{8}$-in., $\frac{3}{4}$-in., and $1\frac{1}{2}$-in. The weight of sample for the different sizes shall be not less than indicated in the following table:

Size of Particles Making up Sample	Weight of Sample, min., g.
No. 4 to $\frac{3}{8}$-in.	1000
$\frac{3}{8}$ to $\frac{3}{4}$-in.	2000
$\frac{3}{4}$ to $1\frac{1}{2}$-in.	3000
Over $1\frac{1}{2}$-in.	5000

(*e*) In the case of mixtures of fine and coarse aggregates, the material shall be separated into two sizes on the No. 4 (4760-micron) sieve, and the samples of fine and coarse aggregates shall be prepared in accordance with Paragraphs (*c*) and (*d*).

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1938 to 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

4. The sample shall be spread in a thin layer on the bottom of the container and examined for clay lumps. Any particles which can be broken into finely divided particles with the fingers shall be classified as clay lumps. After all discernible clay lumps have been broken, the residue from the clay lumps shall be removed by use of the sieves indicated in the following table:

Size of Particles Making up Sample	Size of Sieve for Sieving Residue of Clay Lumps
Fine aggregate (retained on No. 16 (1190-micron) sieve)	No. 20 (840-micron)
No. 4 to ⅜-in.	No. 8 (2380-micron)
⅜ to ¾-in.	No. 4 (4760-micron)
¾ to 1½-in.	No. 4 (4760-micron)
Over 1½-in.	No. 4 (4760-micron)

Calculation

5. The percentage of clay lumps shall be calculated to the nearest 0.1 per cent in accordance with the following formula:

$$L = \frac{W - R}{W} \times 100$$

where:

L = percentage of clay lumps,

W = weight of sample, and

R = weight of sample after removal of clay lumps.

Standard Method of Test for
COAL AND LIGNITE IN SAND[1]

A.S.T.M. Designation: C 123 - 44

ADOPTED, 1939; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 123; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers a procedure for the approximate determination of coal and lignite in the routine laboratory examination of sands. This method separates along with the coal and lignite other particles of low specific gravity, such as small pieces of wood, vegetable matter, etc.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance having a capacity of at least 200 g. and sensitive to 0.01 g. A less sensitive balance may be used in weighing the wet sample.

(*b*) *Container.*—A container suitable for drying the sand sample.

(*c*) *Beakers.*—Two 400-ml. tall-form, lipped beakers.

(*d*) *Wire Gauze or Sieve.*—Wire gauze or a small sieve having about thirty openings per inch. A piece of wire gauze would probably be more suitable than a sieve.

(*e*) *Hot Plate or Oven.*

Procedure

3. A quantity in excess of 200 g. of sand (sampled wet) shall be dried to constant weight at a temperature of approximately 105 C. A 200-g. sample of the dried sand shall then be weighed to the nearest 0.01 g. The sample shall then be poured slowly into about 250 ml. of a liquid having a specific gravity of 2.0 (Note) contained in one of the 400-ml. beakers. The liquid shall then be poured off into the second beaker passing it through the gauze or sieve. Care shall be taken that only the floating particles are poured off with the liquid and that none of the sand is decanted onto the gauze or sieve. The liquid collected in the second beaker shall then be returned to the beaker containing the sand, and, after further agitation of the sample by stirring, the decanting process just described shall be repeated until the sample is free of floating particles. The decanted par-

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1939.

ticles contained on the gauze or sieve shall be washed in carbon tetrachloride, until the flotation liquid is removed, and then dried. The particles will dry very quickly, but may be placed in an oven at 105 C. for a few minutes if desired. The decanted particles shall then be brushed from the gauze or sieve onto the balance pan and the weight accurately determined to the nearest 0.01 g.

NOTE.—Such a liquid can be prepared from an appropriate mixture of carbon tetrachloride and acetylene tetrabromide or bromoform and monobromo-benzene.

Calculation

4. The approximate percentage of coal and lignite shall be calculated from the following formula:

$$\text{Coal and lignite, per cent} = \frac{\text{Wt. of decanted particles}}{\text{Wt. of dry sample (200 g.)}} \times 100$$

Standard Method of Test for

ORGANIC IMPURITIES IN SANDS FOR CONCRETE[1]

A.S.T.M. Designation: C 40 – 33

ADOPTED, 1922; REVISED, 1927, 1933.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 40; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for an approximate determination of the presence of injurious organic compounds in natural sands which are to be used in cement mortar or concrete. The principal value of the test is to furnish a warning that further tests of the sands are necessary before they are approved for use.

Sample

2. A representative test sample of sand weighing about 1 lb. shall be obtained by quartering or by the use of a sampler.

Reference Standard Color Solution

3. A reference standard color solution shall be prepared by adding 2.5 ml. of a 2 per cent solution of tannic acid in 10 per cent alcohol to 97.5 ml. of a 3 per cent sodium hydroxide[3] solution. This shall be placed in a 12-oz. bottle, stoppered, shaken vigorously, and allowed to stand for 24 hr.

Procedure

4. (*a*) A 12-oz. graduated clear glass bottle shall be filled to the 4½-oz. mark with the sample of the sand to be tested.

(*b*) A 3 per cent solution of sodium hydroxide[3] in water shall be added until the volume of the sand and liquid indicated after shaking is 7 liquid ounces.

(*c*) The bottle shall be stoppered, shaken vigorously, and then allowed to stand for 24 hr.

Determination of Color Value

5. (*a*) After standing 24 hr., the color of the clear liquid above the sample shall be compared with the color of the reference standard color solution prepared at the same time and in accordance with Section 3, or with a glass having a color similar to the color of the reference standard solution. Solutions darker in color than the reference standard color have a "color value" higher than 500 ppm. in terms of tannic acid.

(*b*) In lieu of the method described in Paragraph (*a*), the color of the clear liquid above the sample may be compared with the colors given in Figs. 1 to 5 (the accompanying Color Plate I).

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1921 to 1922. Editorially revised and rearranged in 1939.

[3] Where chemically pure sodium hydroxide is not available, commercial soda lye may be used.

Standard Method of Test for

AMOUNT OF MATERIAL FINER THAN NO. 200 SIEVE IN AGGREGATES[1]

A.S.T.M. Designation: C 117 - 37

ADOPTED, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 117; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test outlines the procedure for determining the total quantity of material finer than a standard No. 200 (74-micron) sieve in aggregates.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Sieves.*—A nest of two sieves, the first being a No. 200 (74-micron) sieve conforming to the requirements of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[3] and the second, a sieve having approximately 16 meshes per linear inch.

(*b*) *Container.*—A pan or vessel of a size sufficient to contain the sample covered with water and to permit of vigorous agitation without inadvertent loss of any part of the sample or water.

Test Sample

3. The test sample shall be selected from material which has been thoroughly mixed and which contains sufficient moisture to prevent segregation. A representative sample, sufficient to yield not less than the appropriate weight of dried material, as shown in the following table, shall be selected:

NOMINAL DIAMETER OF LARGEST PARTICLE, IN.	APPROXIMATE MINIMUM WEIGHT OF SAMPLE, KG.
$\frac{1}{4}$	0.5
$\frac{3}{4}$	2.5
$1\frac{1}{2}$ or over	5.0

Procedure

4. (*a*) The test sample shall be dried to constant weight at a temperature not exceeding 110 C. (230 F.) and weighed to the nearest 0.02 per cent.

(*b*) The test sample after being dried and weighed shall be placed in the con-

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1937.

This method is in effect a revision of and replaces the former Standard Method of Test for Quantity of Clay and Silt in Gravel for Highway Construction (D 72 - 21) and the Standard Method of Decantation Test for Sand and Other Fine Aggregates (D 136 - 28) which methods were accordingly discontinued in 1937.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

tainer and sufficient water added to cover it. The contents of the container shall be agitated vigorously and the wash water poured immediately over the nested sieves, arranged with the coarser sieve on top.

(*c*) The agitation should be sufficiently vigorous to result in the complete separation from the coarse particles of all particles finer than the No. 200 (74-micron) sieve and bring the fine material into suspension in order that it will be removed by decantation of the wash water. Care shall be taken to avoid, as much as possible, the decantation of the coarse particles of the sample. The operation shall be repeated until the wash water is clear.

(*d*) All material retained on the nested sieves shall be returned to the washed sample. The washed aggregate shall be dried to constant weight at a temperature not exceeding 110 C. (230 F.) and weighed to the nearest 0.02 per cent.

Calculation

5. The results shall be calculated from the following formula:

$$\text{Percentage of material finer than No. 200 sieve} = \frac{\text{orig. dry wt.} - \text{dry wt. after washing}}{\text{orig. dry wt.}} \times 100$$

Check Determinations

6. When check determinations are desired, the wash water shall be either evaporated to dryness or filtered through tared filter paper which shall subsequently be dried, the residue weighed, and the percentage calculated from the following formula:

$$\text{Percentage of material finer than No. 200 sieve} = \frac{\text{wt. of residue}}{\text{orig. dry wt.}} \times 100$$

Standard Method of Test for

SIEVE ANALYSIS OF FINE AND COARSE AGGREGATES[1]

A.S.T.M. Designation: C 136 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 136; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers a procedure for the determination of the particle size distribution of fine and coarse aggregates, using sieves with square openings. The method is also applicable to the use of laboratory screens with round openings. It is not intended for use in the sieve analysis of aggregates recovered from bituminous mixtures or for the sieve analysis of mineral fillers.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—The balance or scale shall be sensitive to within 0.1 per cent of the weight of the sample to be tested.

(*b*) *Sieves.*—The sieves with square openings shall be mounted on substantial frames constructed in a manner that will prevent loss of material during sieving. Suitable sieve sizes shall be selected to furnish the information required by the specifications covering the material to be tested. The woven wire cloth sieves shall conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

NOTE.—If round-hole perforated plate screens are used, the openings shall conform to the applicable dimensions and tolerances prescribed in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

Samples

3. (*a*) Samples for sieve analysis shall be obtained, by quartering or by use of a sampler, from a representative sample selected from the material to be tested.

(*b*) Samples of fine aggregate for sieve analysis shall weigh, after drying, not

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1938 to 1939.

This method represents a consolidation of the former Standard Methods of Mechanical Analysis of Sand or Other Fine Highway Material, Except Fine Aggregates Used in Cement Concrete (D 7 - 27), of Mechanical Analysis of Broken Stone or Broken Slag, Except Aggregates Used in Cement Concrete (D 18 - 16), of Mechanical Analysis of Mixtures of Sand or Other Fine Material with Broken Stone or Broken Slag, Except Aggregates Used in Cement Concrete (D 19 - 16), and Test for Sieve Analysis of Aggregates for Concrete (C 41 - 36), which standards were accordingly discontinued in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

less than the amount indicated in the following table:

Material with at least 95 per cent finer than a No. 10 (2000-micron) sieve.... 100 g.
Material with at least 90 per cent finer than a No. 4 (4760-micron) sieve and more than 5 per cent coarser than a No. 10 (2000-micron) sieve.....500 g.

(*c*) Samples of coarse aggregate for sieve analysis shall weigh, after drying, not less than an amount indicated in the following table:

Nominal Maximum Size of Particle, in.	Minimum Weight of Sample, g.[a]
⅜	1 000
½	2 500
¾	5 000
1	10 000
1½	15 000
2	20 000
2½	25 000
3	30 000
3½	35 000

[a] For samples weighing 5000 g. or more it is recommended that sieves mounted in frames 16 in. in diameter or larger be used.

(*d*) In the case of mixtures of fine and coarse aggregates, the material shall be separated into two sizes on the No. 4 (4760-micron) sieve and the samples of fine and coarse aggregates shall be prepared in accordance with Paragraphs (*b*) and (*c*).

(*e*) In the case of fine aggregate, the material finer than the No. 200 (74-micron) sieve shall be determined in accordance with the Standard Method of Test for Amount of Material Finer than No. 200 Sieve in Aggregates (A.S.T.M. Designation: C 117) of the American Society for Testing Materials[3] and the sieve analysis made on the material coarser than the No. 200 (74-micron) sieve.

Preparation of Sample

4. Samples shall be dried to substantially constant weight at a temperature not exceeding 110 C. (230 F.).

Procedure

5. (*a*) The sample shall be separated into a series of sizes using such sieves as are necessary to determine compliance with the specifications for the material under test. The sieving operation shall be conducted by means of a lateral and vertical motion of the sieve, accompanied by jarring action so as to keep the sample moving continuously over the surface of the sieve. In no case shall fragments in the sample be turned or manipulated through the sieve by hand. Sieving shall be continued until not more than 1 per cent by weight of the residue passes any sieve during 1 min. On that portion of the sample retained on the No. 4 (4760-micron) sieve, the above described procedure for determining thoroughness of sieving shall be carried out with a single layer of material. When mechanical sieving is used, the thoroughness of sieving shall be tested by using the hand method of sieving as described above.

(*b*) The weight of each size shall be determined on a scale or balance conforming to the requirements specified in Section 2 (*a*).

Report

6. The results of the sieve analysis shall be reported as follows: (*a*) total percentages passing each sieve, or (*b*) total percentages retained on each sieve, or (*c*) percentages retained between consecutive sieves, depending upon the form of the specifications for the use of the material under test. Percentages shall be reported to the nearest whole number and shall be calculated on the basis of the weight of the test sample including any material finer than the No. 200 (74-micron) sieve.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.5-1943

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 85-42

Standard Method of Test for

SPECIFIC GRAVITY AND ABSORPTION OF COARSE AGGREGATE[1]

A.S.T.M. Designation: C 127 - 42

ADOPTED, 1939; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 127; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) This method of test is intended for use in making determinations of bulk and apparent specific gravity, and absorption (after 24 hr. in water at room temperature) of coarse aggregate. The bulk specific gravity is the value generally desired for calculations in connection with portland-cement concrete.

(*b*) This method determines directly the bulk specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] or the bulk specific gravity on the basis of weight of saturated surface-dry aggregate, or the apparent specific gravity as defined in the Standard Definitions E 12.[3]

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance having a capacity of 5 kg. or more and sensitive to 0.5 g. or less.

(*b*) *Wire Basket.*—A wire basket of No. 4 mesh, approximately 8 in. in diameter and 8 in. in height.

(*c*) A suitable container for immersing the wire basket in water and suitable apparatus for suspending the wire basket from center of scale pan of balance.

Sample

3. Approximately 5 kg. of the aggregate shall be selected from the sample to be tested by the method of quartering, rejecting all material passing a $\frac{3}{8}$-in. sieve. In the case of homogeneous aggregate, all material may be retained on a 1-in. sieve.

---

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1939.

This method represents a consolidation of the former Standard Methods of Test for Apparent Specific Gravity of Coarse Aggregates (D 30 - 18), Test for Absorption by Aggregates for Concrete (Laboratory Determination) (C 93 - 36), Field Test for Absorption of Mixing Water by Aggregates for Concrete (C 96 - 36), and the former Tentative Method of Test for Apparent Specific Gravity of Coarse Aggregates in a Saturated Condition (C 86 - 31 T), which methods were accordingly discontinued in 1936.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

4. (*a*) After thoroughly washing to remove dust or other coatings from the surface of the particles, the sample shall be dried to constant weight at a temperature of 100 to 110 C. (Note) and then immersed in water at 15 to 25 C., for a period of 24 hr. It shall then be removed from the water and rolled in a large absorbent cloth until all visible films of water are removed, although the surfaces of the particles still appear to be damp. The larger fragments may be individually wiped. Care should be taken to avoid evaporation during the operation of surface drying. The weight of the sample in the saturated surface-dry condition shall then be obtained. This and all subsequent weights shall be determined to the nearest 0.5 g.

NOTE.—Where the absorption and specific gravity values may be utilized as a basis for designing concrete mixtures with aggregates normally used in a moist condition, the requirement of drying to constant weight may be eliminated.

(*b*) After weighing, the saturated surface-dry sample shall be placed immediately in the wire basket and its weight in water determined.

(*c*) The sample shall then be dried to constant weight at a temperature of 100 to 110 C., cooled to room temperature, and weighed.

Bulk Specific Gravity

5. The bulk specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] shall be calculated from the following formula:

$$\text{Bulk sp. gr.} = \frac{A}{B - C}$$

where:

A = weight in grams of oven-dry sample in air,
B = weight in grams of saturated surface-dry sample in air, and
C = weight in grams of saturated sample in water.

Bulk Specific Gravity (Saturated Surface-Dry Basis)

6. The bulk specific gravity on the basis of weight of saturated surface-dry aggregate shall be calculated from the following formula:

$$\text{Bulk sp. gr. (saturated surface-dry basis)} = \frac{B}{B - C}$$

Apparent Specific Gravity

7. The apparent specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] shall be calculated from the following formula:

$$\text{Apparent sp. gr.} = \frac{A}{A - C}$$

Absorption

8. The percentage of absorption shall be calculated from the following formula:

$$\text{Absorption, per cent} = \frac{B - A}{A} \times 100$$

Reproducibility of Results

9. Duplicate determinations should check to within 0.02 in the case of specific gravity and 0.05 per cent in the case of percentage of absorption.

Standard Method of Test for

SPECIFIC GRAVITY AND ABSORPTION OF FINE AGGREGATE[1]

A.S.T.M. Designation: C 128 - 42

ADOPTED, 1939; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 128; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) This method of test is intended for use in making determinations of bulk and apparent specific gravity, and absorption (after 24 hr. in water at room temperature) of fine aggregate. The bulk specific gravity is the value generally desired for calculations in connection with portland-cement concrete.

(*b*) This method determines directly the bulk specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] or the bulk specific gravity on the basis of weight of saturated surface-dry aggregate, or the apparent specific gravity as defined in the Standard Definitions E 12.[3]

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance having a capacity of 1 kg. or more and sensitive to 0.1 g. or less.

(*b*) *Flask.*—A volumetric flask of 500-ml. capacity, calibrated to 0.15 ml. at 20 C.

(*c*) *Conical Mold.*—A conical metal mold $1\frac{1}{2}$ in. in diameter at the top, $3\frac{1}{2}$ in. in diameter at the bottom, and $2\frac{3}{4}$ in. in height.

(*d*) *Tamping Rod.*—A metal tamping rod weighing 12 oz. and having a flat circular tamping face 1 in. in diameter.

Preparation of Sample

3. Approximately 1000 g. of the fine aggregate selected from the sample by the method of quartering shall be placed, in a suitable pan or vessel, after drying to constant weight at a temperature of 100 to 110 C. (Note 1), covered with water, and permitted to stand for 24 hr. The sample shall then be spread on a flat surface, exposed to a gently moving current of warm air, and stirred frequently to secure uniform drying. This operation shall be continued until the fine aggregate approaches a free-flowing condition. The fine aggregate shall then be

---

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1939.

This method represents a consolidation of the former Standard Methods of Test for Approximate Apparent Specific Gravity of Fine Aggregate (C 65 - 30), Test for Apparent Specific Gravity of Sand, Stone, and Slag Screenings, and other Fine Non-Bituminous Highway Materials (D 55 - 25), Test for Absorption by Aggregates for Concrete (Laboratory Determinations) (C 95 - 36), and Field Test for Absorption of Mixing Water by Aggregates for Concrete (C 96 - 36), which methods were accordingly discontinued.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

placed loosely in the conical mold, the surface lightly tamped 25 times with the metal rod, and the mold lifted vertically. If free moisture is present, the cone of fine aggregate will retain its shape. Drying with constant stirring shall be continued and tests made at frequent intervals, until the cone of fine aggregate slumps upon removal of the mold. This indicates that the fine aggregate has reached a surface-dry condition (Note 2).

NOTE 1.—Where the absorption and specific gravity values may be utilized as a basis for designing concrete mixtures with aggregates normally used in a moist condition, the requirement of drying to constant weight may be eliminated.

NOTE 2.—The procedure described in Section 3 is intended to insure that the first trial determination shall be made with some free water in the sample. If the cone of fine aggregate slumps on the first trial, the fine aggregate has been dried past the saturated and surface-dry condition. In this case a few milliliters of water shall be thoroughly mixed with the fine aggregate and the sample permitted to stand in a covered container for 30 min. The process of drying and testing the fine aggregate shall then be resumed.

Procedure

4. (*a*) A 500.0-g. sample of the material, prepared as described in Section 3, shall be introduced immediately into the flask and the flask filled almost to the 500-ml. mark with water at a temperature of 20 C. The flask shall then be rolled on a flat surface to eliminate all air bubbles, after which it shall be placed in a constant temperature bath maintained at 20 C. After approximately 1 hr. it shall be filled with water to the 500-ml. mark and the total weight of water (Note) introduced into the flask shall be determined to the nearest 0.1 g.

NOTE.—If desired, the quantity of water necessary to fill the flask may be determined volumetrically by the use of a burette accurate to 0.1 ml.

(*b*) The fine aggregate shall be removed from the flask and dried to constant weight at a temperature of 100 to 110 C., cooled to room temperature in a desiccator, and weighed.

Bulk Specific Gravity

5. The bulk specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] shall be calculated from the following formula:

$$\text{Bulk sp. gr.} = \frac{A}{V - W}$$

where:

A = weight in grams of oven-dry sample in air,
V = volume in milliliters of flask, and
W = weight in grams or volume in milliliters of water added to flask.

Bulk Specific Gravity (Saturated Surface-Dry Basis)

6. The bulk specific gravity on the basis of weight of saturated surface-dry aggregate shall be calculated from the following formula:

$$\text{Bulk sp. gr. (saturated surface-dry basis)} = \frac{500}{V - W}$$

Apparent Specific Gravity

7. The apparent specific gravity as defined in the Standard Definitions of Terms Relating to Specific Gravity (A.S.T.M. Designation: E 12) of the American Society for Testing Materials,[3] shall be calculated from the following formula:

$$\text{Apparent sp. gr.} = \frac{A}{(V - W) - (500 - A)}$$

Absorption

8. The percentage of absorption shall be calculated from the following formula:

$$\text{Absorption, per cent} = \frac{500 - A}{A} \times 100$$

Reproducibility of Results

9. Duplicate determinations should check to within 0.02 in the case of specific gravity and 0.05 per cent in the case of percentage of absorption.

Standard Method of Test for

STRUCTURAL STRENGTH OF FINE AGGREGATE USING CONSTANT WATER-CEMENT-RATIO MORTAR[1]

A.S.T.M. Designation: C 87 - 44

ADOPTED, 1936; REVISED, 1939, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 87; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the "structural strength" of sands to be used as fine aggregate in concrete by means of a compression test on a mortar of plastic consistency and gaged to a definite water-cement ratio.

Mortar

2. Cement and water (Section 5) in quantities[3] that will give a water-cement ratio of 0.6 by weight shall be placed in an appropriate vessel[4] and the cement permitted to absorb water for 1 min. The materials shall then be mixed with a spoon[4] into a smooth paste. A sample of sand of known weight[5] that has been placed in a saturated surface-dry condition[5] by means of the procedure specified in Section 3 of the Standard Method of Test for Specific Gravity and Absorption of Fine Aggregate (A.S.T.M. Designation: C 128) of the American Society for Testing Materials,[6] shall be beaten into the mixture until the material appears to be of the desired consistency (flow 100 ± 5). The mixing shall be continued for 30 sec. and a determination of the flow made in accordance with Section 3.

Flow Test

3. (*a*) *Apparatus.*—The flow test shall be made on a 10-in. flow table consisting of a circular bronze plate 10 in. in diameter, so mounted that the surface is level, and equipped with a mechanism for raising the plate ½ in. and allowing it to fall without cushioning. The flow table with the attached shaft shall weigh 9 ± 1 lb. The frame of the table shall

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1931 to 1936, being revised in 1932.

[3] For six 2-in. cubes, 600 g. of cement and 360 ml. of water will usually give sufficient mortar. The quantity of sand used with this amount of cement may vary from 1200 g. for fine sand to 2000 g. or more for coarse sand.

[4] An ordinary sauce pan of 4-qt. capacity, 9½ in. in diameter at the top and 4½ in. in height, and a large iron kitchen spoon are suitable for use in mixing the mortar.

[5] If the absorption as determined by the Standard Method C 128 is known, sand may be prepared for test by adding to a known weight of dry sand the amount of water it will absorb, mixing thoroughly, and permitting the sand to stand in a covered pan for 30 min. before use.

[6] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

be attached rigidly to a concrete pedestal which in turn shall be attached rigidly to the floor. The concrete pedestal shall be at least 8 in. in diameter and 25 in. in height and shall weigh at least 100 lb. A right truncated cone, $2\frac{3}{4}$ in. in diameter at the top, 4 in. in diameter at the bottom, and 2 in. in height shall be used to measure the volume of the mortar for the test.

(*b*) *Procedure.*—Immediately after mixing, the mortar shall be placed in the cone which has been carefully centered on the flow table. The mortar shall be rodded 25 times with a $\frac{3}{8}$-in. rod, the surplus struck off, the plate wiped clean, the cone removed, and the table given 10 drops in 10 sec. The percentage of increase in the diameter of the base of the pat, measured on two diameters at right angles to each other, shall be recorded as the flow. Should the flow be too great, the mortar may be returned to the mixing vessel, additional sand added, and another determination of the flow made. If more than two trials must be made to obtain a flow of 100 ± 5, the mortar should be considered as a trial mortar and the test specimens prepared from a new batch. If the mortar is too dry, the batch shall be discarded. The quantity of sand used shall be determined by subtracting the weight of the portion remaining after mixing from the weight of the initial sample.

Molding Specimens

4. Immediately following the determination of the flow, the mortar shall be placed in 2 by 4-in. cylindrical molds in three layers or in 2-in. cubes in two layers, each layer rodded in place with 25 strokes of a $\frac{3}{8}$-in. rod, and the mold filled to overflowing. The specimens shall be placed in a moist closet for curing. Three to four hours after molding the specimens shall be struck off to a smooth surface. Twenty to twenty-four hours after molding, the specimens shall be removed from the molds and stored in water until tested.

Temperature

5. The temperature of the mixing water, moist closet, and storage tank shall be maintained between 65 and 75 F.

Capping Specimens

6. If the specimens are cylindrical, they shall be capped before testing in such a manner that the ends are perfectly plane and at right angles to the axis of the cylinder. The material used for capping and the thickness of the cap shall be such that it will not flow or fracture under the load. Cubes made in suitable molds need not be capped and shall be tested at right angles to the direction of molding.

NOTE.—It is desirable that the capping material have a value for modulus of elasticity equal to or greater than that of the mortar.

Standard Method of Test for
UNIT WEIGHT OF AGGREGATE[1]

A.S.T.M. Designation: C 29 - 42

ADOPTED, 1921; REVISED, 1927, 1939, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 29; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedures for determining the unit weight of fine, coarse, or mixed aggregates.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance or scale sensitive to 0.5 per cent of the weight of the sample to be weighed.

(*b*) *Tamping Rod.*—A straight metal rod, $\frac{5}{8}$ in. in diameter and 24 in. in length, with one end tapered for a distance of 1 in. to a blunt bullet-shaped point.

(*c*) *Measure.*—A metal measure, cylindrical in form and preferably provided with handles. It shall be watertight, with the top and bottom true and even, preferably machined to accurate dimensions on the inside, and of sufficient rigidity to retain its form under rough usage. The $\frac{1}{2}$ and 1-cu. ft. measures shall be reinforced around the top with a No. 10 to No. 12 gage steel band $1\frac{1}{2}$ in. in width. The measures required, depending upon the maximum size of the coarsest particles in the aggregate to be tested, shall have capacities of $\frac{1}{10}$, $\frac{1}{2}$, or 1 cu. ft. and shall conform to the following dimensional requirements:

Capacity, cu. ft.	Inside Diameter, in.	Inside Height, in.	Thickness of Metal, U. S. Gage	Size of Largest Particles of Aggregate, in.
$\frac{1}{10}$	6.00	6.10	No. 10 to No. 12	$\frac{1}{2}$
$\frac{1}{2}$	10.00	11.00	No. 10 to No. 12	$1\frac{1}{2}$
1	14.00	11.23	No. 10 to No. 12	4

Calibration of Measure

3. The measure shall be calibrated by accurately determining the weight of water at 16.7 C. (62 F.) required to fill it. The factor for any unit shall be obtained by dividing the unit weight of water at 16.7 C. (62 F.) (62.355 lb. per cu. ft.) by the weight of water at 16.7 C. (62 F.) required to fill the measure.

Sample

4. The sample of aggregate shall be room dry and thoroughly mixed.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1920 to 1921.

Compact Weight Determination

Rodding Procedure

5. The rodding procedure is applicable to aggregates having a maximum size of 2 in. or less.

(*a*) The measure shall be filled one-third full and the top leveled off with the fingers. The mass shall be rodded with the tamping rod with 25 strokes, evenly distributed over the surface. The measure shall be filled two-thirds full and again rodded with 25 strokes as before. The measure shall then be filled to overflowing, rodded 25 times, and the surplus aggregate struck off, using the tamping rod as a straight edge.

(*b*) In rodding the first layer, the rod shall not be permitted to forcibly strike the bottom of the measure. In rodding the second and final layers, only enough force shall be used to cause the tamping rod to penetrate the last layer of aggregate placed in the measure.

(*c*) The net weight of the aggregate in the measure shall be determined. The unit weight of the aggregate shall then be obtained by multiplying the net weight of the aggregate by the factor found as described in Section 3.

Jigging Procedure

6. The jigging procedure is applicable to aggregates having a maximum size greater than 2 in. and not to exceed 4 in.

(*a*) The measure shall be filled in three approximately equal layers as described in Section 5 (*a*), each layer being compacted by placing the measure on a firm foundation, such as a cement-concrete floor, and raising alternate sides of the measure about 2 in. from the foundation and allowing it to drop in such a manner as to hit with a sharp, slapping blow. The aggregate particles, by this procedure, will arrange themselves in a closely compacted condition. Each layer shall be compacted by dropping the measure 50 times in the manner described, 25 times on each side. The surface of the aggregate shall then be leveled off with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate shall balance the larger voids in the surface below the top of the measure.

(*b*) The net weight of the aggregate in the measure shall be determined. The unit weight of the aggregate shall then be obtained by multiplying the net weight of the aggregate by the factor found as described in Section 3.

Loose Weight Determination

Shoveling Procedure

7. (*a*) The shoveling procedure is applicable to aggregates having a maximum size of 4 in. or less. The measure shall be filled to overflowing by means of a shovel or scoop, the aggregate being discharged from a height of not to exceed 2 in. above the top of the measure. Care shall be taken to prevent, so far as possible, segregation of the particle sizes of which the sample is composed. The surface of the aggregate shall then be leveled off with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate shall balance the larger voids in the surface below the top of the measure.

(*b*) The net weight of the aggregate in the measure shall be determined. The unit weight of the aggregate shall then be obtained by multiplying the net weight of the aggregate by the factor found as described in Section 3.

Reproducibility of Results

8. Results with the same sample should check within 1 per cent.

AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A19-1937

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 20-42

Standard Method of Test for

VOIDS IN AGGREGATE FOR CONCRETE[1]

A.S.T.M. Designation: C 30 - 37

ADOPTED, 1922; REVISED, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 30; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test outlines the procedure for determining voids in aggregate.

Percentage of Voids

2. The voids in aggregate shall be determined by the following formula:

$$\text{Percentage of voids} = \frac{(\text{sp. gr.} \times 62.355) - \text{Wt.}}{\text{sp. gr.} \times 62.355} \times 100$$

where:

sp. gr. = the bulk specific gravity of the aggregate as determined by the appropriate method referred to in Section 3 (*a*) or (*b*),

62.355 = the weight in pounds of 1 cu. ft. of water at the standard temperature of 16.7 C. (62 F.), and

Wt. = the weight in pounds per cubic foot of the aggregate as determined by the method referred to in Section 3 (*c*).

NOTE.—For complete accuracy, "Wt." should be the weight of the air-dried sample minus the weight of any contained moisture.

Methods of Testing

3. The specific gravity and weight of the aggregate shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Specific Gravity of Fine Aggregate.*—Standard Method of Test for Specific Gravity and Absorption of Fine Aggregate (A.S.T.M. Designation: C 128),[3] Section 5.

(*b*) *Specific Gravity of Coarse Aggregate.*—Standard Method of Test for Specific Gravity and Absorption of Coarse Aggregate (A.S.T.M. Designation: C 127),[3] Section 5.

(*c*) *Unit Weight of Aggregate.*—Standard Method of Test for Unit Weight of Aggregate (A.S.T.M. Designation: C 29).[3]

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1920 to 1922.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Definition of

THE TERM SAND[1]

A.S.T.M. Designation: C 58 – 28

ADOPTED, 1928.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 58; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Sand.—The fine granular material (usually less than $\frac{1}{4}$ in. in diameter) resulting from the natural disintegration of rock, or from the crushing of friable sandstone rocks.

NOTE.—When used without a qualifying adjective, the term sand is generally understood to mean the product of the natural disintegration of siliceous or calcareous rock. Sand should be distinguished from screenings, gravel, etc. The size of particle and other physical characteristics should be taken care of in specifications. The fine material resulting from the crushing of blast-furnace slag is known as "slag sand."

[1] Under the standardization procedure of the Society, this definition is under the jurisdiction of the A.S.T.M. Committee E-8 on Nomenclature and Definitions.

[2] Prior to adoption as standard, this definition was published as tentative from 1924 to 1928, being revised in 1925 and 1926.

A "tentative revision" of this standard appears in the Tenta-

Standard Specifications for

READY-MIXED CONCRETE[1]

A.S.T.M. Designation: C 94 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 94; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover ready-mixed concrete for general use. Requirements for quality of materials and for proportions and quality of concrete shall be either as herein specified or as specified by the purchaser by reference to applicable general specifications for concrete. Applicable general specifications to which reference is made by the purchaser shall be considered a part of these specifications. In any case where the requirements of such general specifications are in conflict with these specifications the requirements of the general specifications shall govern unless otherwise specified by the purchaser.

(*b*) For the purpose of these specifications, ready-mixed concrete is portland-cement concrete manufactured for delivery to a purchaser in a plastic and unhardened state and delivered in a truck mixer or a truck agitator.

Basis of Purchase

2. (*a*) The basis of purchase shall be the cubic yard of plastic and unhardened concrete as delivered to the purchaser.

(*b*) The volume of plastic and unhardened concrete in a given batch shall be determined in accordance with the Standard Method of Test for Weight per Cubic Foot, Yield, and Air Content (Gravimetric) of Concrete (A.S.T.M. Designation: C 138)[3] based on the total weight of the batch, determined either from the weights of all materials, including water, entering the batch or directly from the net weight of the concrete in the batch as delivered.

Materials

3. (*a*) In the absence of designated applicable specifications covering requirements for quality of materials, the following specifications shall govern:

(*1*) *Portland Cement.*—Portland cement shall conform to the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150).[3] The purchaser should specify the type required, but if no type is specified, the

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1933 to 1935. They were adopted in 1935, published as standard from 1935 to 1942, being revised in 1938, but further revised and issued as tentative in 1941, revised in 1942, 1943, and 1944.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

requirements of type I as prescribed in Specifications C 150 shall apply.

(2) *Aggregates.*—Aggregates shall conform to the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33).[3]

(3) *Water.*—Water shall be clear and free from injurious amounts of oil, acid, alkali, organic matter, or other deleterious substances.

(*b*) Admixtures, if to be used, shall be provided for in the contract or in the designated applicable specifications for concrete.

Quality of Concrete

4. In the absence of designated applicable general specifications, the purchaser shall select one of the two following alternate bases for specifying the quality of the concrete:

Alternate No. 1:

(*a*) When the purchaser requires the manufacturer to assume responsibility for the design of the concrete mixture, the purchaser shall specify the following:

(1) Minimum allowable compressive or flexural strength as determined on samples taken at point of delivery. The basis shall be either the compressive strength at 28 days or the flexural strength at 14 days (Note). The purchaser shall specify the requirements for strength in terms of tests of standard specimens cured under standard laboratory conditions for moist curing. The purchaser, in selecting the minimum allowable compressive or flexural strength to be specified, shall give consideration to requirements for durability, surface texture, and density, in addition to those for structural design.

(2) Designated size, or sizes, of coarse aggregate.

(3) Maximum and minimum allowable slump at point of delivery.

NOTE.—Table I suggests a basis for the selection of minimum allowable compressive strengths which, for average normal portland cement, will result in the use of water-cement ratios that will produce concrete suitable for various types of structures and conditions of exposure. A corresponding table of flexural strengths is not given because of the wider range in values which may be obtained with a given water-cement ratio for different materials.

(*b*) Prior to the execution of the contract, the manufacturer shall furnish a statement to the purchaser, giving the proportions by weight (dry) of cement, fine and coarse aggregates which will be used in the manufacture of each class of concrete ordered by the purchaser. If required, he shall also furnish evidence satisfactory to the purchaser that the proportions selected will produce concrete of the quality specified.

Alternate No. 2:

(*a*) When the purchaser assumes responsibility for the design of the concrete mixture, he shall specify the following:

(1) Cement content in bags per cubic yard of concrete, or equivalent units.

(2) Designated size, or sizes, of coarse aggregate.

(3) Maximum allowable water content in gallons per bag of cement, or equivalent units, including surface moisture, but excluding water of absorption, of the aggregates.

(4) Maximum and minimum allowable slump at point of delivery.

(*b*) Prior to the actual delivery of the concrete, the manufacturer shall furnish a statement to the purchaser giving the proportions by weight (dry) of cement, fine and coarse aggregates which will be used in the manufacture of each class of concrete ordered by the purchaser. Such proportions shall be subject to the approval of the purchaser.

Range in Slump

5. When the maximum allowable slump is 3 in. or less, the difference be-

tween the specified maximum and minimum slumps shall be 1 in. When the maximum allowable slump is greater than 3 in., the difference between the specified maximum and minimum slumps shall be 2 in.

other materials. When cement is measured in bags, no fraction of a bag shall be used unless weighed.

(*b*) Aggregate shall be measured by weight. Batch weights shall be based on dry materials and shall be the required

TABLE I.—COMPRESSIVE STRENGTHS OF CONCRETE SUITABLE FOR VARIOUS CONDITIONS OF EXPOSURE.

NOTE.—Presented as information only and not as a part of the specifications; adapted from Tables 1 and 2 of the Report of the Joint Committee on Standard Specifications for Concrete and Reinforced Concrete, June, 1940.

Type or Location of Structure	Compressive Strength, min., psi. at 28 days							
	Severe or Moderate Climate, Wide Range of Temperatures, Rain and Long Freezing Spells or Frequent Freezing and Thawing				Mild Climate, Rain or Semi-Arid, Rarely Snow or Frost			
	Thin Sections		Moderate Sections		Thin Sections		Moderate Sections	
	Reinforced	Plain	Reinforced	Plain	Heavy and Mass Sections	Reinforced	Plain	Reinforced	Plain	Heavy and Mass Sections
A. At the waterline in hydraulic or waterfront structures or portions of such structures where complete saturation or intermittent saturation is possible, but not where the structure is continuously submerged:										
In sea water	5000	4500			4000	5000	4500			4000
In fresh water	4500	4000			3600	4500	4000			3600
B. Portions of hydraulic or waterfront structures some distance from the waterline, but subject to frequent wetting:										
By sea water	4500	4000			4000	4500	3600			3200
By fresh water	4000	3600			3600	4000	3200			2800
C. Ordinary exposed structures, buildings and portions of bridges not coming under above groups	4000	3600			3200	4000	3200			2800
D. Complete continuous submergence:										
In sea water	4000	3600			3200	4000	3600			3200
In fresh water	3600	3200			2800	3600	3200			2800
E. Concrete deposited through water	....	....	4500		4500	...	...	4500		4500
F. Pavement slabs directly on ground:										
Wearing slabs	4500	4000	...		...	4000	3600	...		...
Base slabs	3600	3200	...		...	3200	2800	...		...

G. Special cases:
(*a*) For concrete exposed to strong sulfate ground waters, or other corrosive liquids or salts, the minimum compressive strength should be 5000 psi.
(*b*) For concrete not exposed to the weather, such as the interior of buildings and portions of structures entirely below ground, no exposure hazard is involved and the compressive strength should be selected on the basis of the structural design requirements.

Measuring Materials

6. (*a*) Cement shall be measured by weight or, if permitted by the purchaser, in bags of 94 lb. each. When cement is measured by weight, it shall be weighed on a scale separate from those used for

weights of dry materials plus the total weight of moisture (both absorbed and surface) contained in the aggregate.

(*c*) Water shall be measured by volume or by weight. The device for the measurement of the water shall be readily adjustable and, under all operating con-

ditions, shall have an accuracy of 1 per cent of the quantity of water required for the batch. The device shall be so arranged that the measurements will not be affected by variable pressures in the water supply line. Measuring tanks shall be equipped with outside taps and valves to provide for checking their calibration unless other means are provided for readily and accurately determining the amount of water in the tank. In the case of truck mixers, if wash water is permitted to be used as a portion of the mixing water for succeeding batches, it shall be accurately measured in a separate tank, provided for the purpose, and taken into account in determining the amount of additional mixing water required.

(*d*) Powdered admixtures shall be measured by weight, and paste or liquid admixtures by weight or volume.

Batching Plant

7. (*a*) Unless otherwise permitted by the purchaser, bins with adequate separate compartments for fine aggregates and for each required size of coarse aggregate shall be provided in the batching plant. Each compartment shall be designed to discharge efficiently and freely into the weighing hopper. Means of control shall be provided so that, as the quantity desired in the weighing hopper is being approached, the material may be added slowly and shut off with precision. A port or other opening for removing an overload of any one of the several materials from the hopper shall be provided. Hoppers shall be constructed so as to eliminate accumulations of tare materials and to discharge fully.

(*b*) The scales for weighing aggregates and cement may be either of the horizontal-beam or of the springless-dial type. They shall be accurate within 1 per cent under operating conditions. Adequate standard test weights shall be available for checking accuracy. All exposed fulcrums, clevises, and similar working parts of scales shall be kept clean. When beam-type scales are used, provision shall be made for indicating to the operator that the required load in the weighing hopper is being approached; the device shall indicate at least the last 200 lb. of load. All weighing and indicating devices shall be in full view of the operator while charging the hopper and he shall have convenient access to all controls.

Mixers and Agitators

8. (*a*) Mixers may be stationary mixers or truck mixers. Agitators may be truck mixers or truck agitators. Each mixer and agitator shall have attached thereto in a prominent place a metal plate on which is plainly marked, for the various uses for which the equipment is designed, the capacity of the drum or container in terms of volume of mixed concrete and the speed of rotation of the mixing drum or blades.

(*b*) The mixer when loaded to capacity shall be capable of combining the ingredients of the concrete within the specified time into a thoroughly mixed and uniform mass and of discharging the concrete with a satisfactory degree of uniformity as indicated in Paragraph (*d*).

(*c*) The agitator when loaded to capacity shall be capable of maintaining the mixed concrete in a thoroughly mixed and uniform mass and of discharging the concrete with a satisfactory degree of uniformity as indicated in Paragraph (*d*).

(*d*) The purchaser may, from time to time, make slump tests of individual samples taken at approximately the one-quarter and the three-quarter points of the load and if the slumps differ by more than 2 in. the mixer or agitator shall not be used unless the condition is corrected or except as provided in Paragraph (*e*).

(*e*) If the requirements of Paragraph (*d*) are not met by mixers operated at the minimum specified mixing time and loaded to capacity, or by agitators when loaded to capacity, the equipment may still be used when operation with a longer mixing time or with a smaller load will permit the requirements of Paragraph (*d*) to be met.

(*f*) Mixers and agitators shall be examined daily for changes in condition due to accumulations of hardened concrete or mortar or to wear of blades. When any such change of condition is found the tests described in Paragraph (*d*) should be repeated.

Mixing and Delivery

9. (*a*) Ready-mixed concrete shall be mixed and delivered to the point designated by the purchaser by means of one of the following combinations of operations:

(*1*) Mixed completely in a stationary mixer and the mixed concrete transported to the point of delivery in a truck agitator or in a truck mixer operating at agitator speed. (Known as *central-mixed concrete.*)

(*2*) Mixed partially in a stationary mixer, and the mixing completed in a truck mixer. (Known as *shrink-mixed concrete.*)

(*3*) Mixed completely in a truck mixer. (Known as *transit-mixed concrete.*)

(*b*) Mixers and agitators shall be operated within the limits of capacity and speed of rotation designated by the manufacturer of the equipment.

(*c*) When a stationary mixer is used for the complete mixing of the concrete, the mixing time for mixers of 1 cu. yd. or less shall not be less than 1 min. For mixers of larger capacities, this minimum shall be increased 15 sec. for each cubic yard or fraction thereof of additional capacity. Mixing time shall be measured from the time all cement and aggregates are in the drum. The batch shall be so charged into the mixer that some water will enter in advance of cement and aggregate, and all water shall be in the drum by the end of the first one-fourth of the specified mixing time.

(*d*) When a stationary mixer is used for partial mixing of the concrete (shrink-mixing), the mixing time in the stationary mixer may be reduced to the minimum required (about 30 sec.) to intermingle the ingredients.

(*e*) When a truck mixer is used either for complete mixing or to finish the partial mixing done in a stationary mixer, each batch of concrete shall be mixed not less than 50 nor more than 100 revolutions of the drum or blades at the rate of rotation designated by the manufacturer of the equipment as mixing speed. Additional mixing, if any, shall be at the speed designated by the manufacturer of the equipment as agitating speed.

(*f*) When a truck mixer or truck agitator is used for transporting concrete which has been completely mixed in a stationary mixer, mixing during transportation shall be at the speed designated by the manufacturer of the equipment as agitating speed.

(*g*) Concrete shall be delivered to the site of the work and discharge from the truck mixer or agitator shall be completed within 1½ hr. after the introduction of the mixing water to the cement and aggregates, or the cement to the aggregates, unless a longer time is specifically authorized by the purchaser. In hot weather, or under conditions contributing to quick stiffening of the concrete, a time less than 1½ hr. may be specified by the purchaser.

(*h*) Concrete delivered in outdoor temperatures lower than 40 F. shall

arrive at the work having a temperature not less than 60 F. nor greater than 90 F., unless otherwise specified or permitted by the purchaser.

Inspection

10. Proper facilities shall be provided for the purchaser to inspect ingredients and processes used in the manufacture and delivery of the concrete. The manufacturer shall afford the inspector representing the purchaser all reasonable facilities, without charge, for securing samples to determine whether the concrete is being furnished in accordance with these specifications. All tests and inspections shall be so conducted as not to interfere unnecessarily with the manufacture and delivery of the concrete.

Sampling

11. Samples of concrete shall be obtained in accordance with the Standard Method of Sampling Fresh Concrete (A.S.T.M. Designation: C 172),[3] except in the case of individual samples secured to determine uniformity of consistency. In securing individual samples to determine uniformity of consistency as provided in Section 8 (*d*), the A.S.T.M. Method C 172 shall be followed, but the requirements shall be so modified as to permit of obtaining two samples, one at the one-quarter point and one at the three-quarter point of the load.

Slump

12. Slump tests shall be made at the option of the purchaser. If the measured slump falls outside the limits specified, a check test shall be made. In the event of a second failure the purchaser may refuse to permit the use of the load of concrete represented.

Certification

13. The purchaser may require the manufacturer of the ready-mixed concrete to furnish, with each load, a statement showing the proportions used in making the concrete. In any event, the manufacturer shall inform the purchaser of any change in proportions.

Strength

14. (*a*) When strength is used as a basis for acceptance of concrete made in accordance with these specifications, standard tests (see Section 17) shall be made frequently by the purchaser and, in general, not less frequently than one strength test for each fifty loads of each class of concrete, except that in no case shall a given class of concrete be represented by less than three tests.

(*b*) For a *strength test* three standard test specimens shall be made from a composite sample secured as required in Section 11. The test result shall be the average of the strengths of the three specimens, except that, if one specimen in a test shows manifest evidence of improper sampling, molding, or testing, it shall be discarded and the remaining two strengths averaged. Should more than one specimen representing a given test show definite defects, the entire test shall be discarded.

(*c*) The representative of the purchaser shall ascertain and record the exact location in the work at which each load represented by a strength test is deposited.

(*d*) To conform to the requirements of these specifications, the average of all of the strength tests representing each class of concrete as well as the average of any five consecutive strength tests representing each class of concrete shall be equal to or greater than the specified strength and no strength test shall have an average value less than 80 per cent of the specified strength.

Alternate Strength Basis

15. The provisions of Section 14 may be waived, at the option of the purchaser,

if the manufacturer can furnish evidence satisfactory to the purchaser that concrete of the proportions and made with the materials which he proposes to use will have the specified strength.

Failure to Meet Specifications

16. In the event that the concrete fails to meet the requirements of these specifications in any respect, the manufacturer of the ready-mixed concrete and the purchaser shall confer to determine if agreement can be reached as to what adjustment, if any, shall be made. If an agreement on a mutually satisfactory adjustment cannot be reached by the manufacturer and the purchaser, a decision shall be made by a panel of three qualified engineers, one of whom shall be designated by the purchaser, one by the manufacturer, and the third chosen by these two members of the panel. The panel shall use such means as it considers appropriate to determine the quality of the concrete, including, if deemed advisable by it, chemical analyses, strength tests of cores cut from the structure, and load tests of the finished structure. The question of responsibility for the cost of such arbitration shall be determined by the panel. Its decision shall be binding except as modified by a court decision.

Methods of Testing

17. Methods of testing ready-mixed concrete shall be in accordance with the following methods of the America Society for Testing Materials:

(*a*) *Slump.*—Standard Method of Slump Test for Consistency of Portland-Cement Concrete (A.S.T.M. Designation: C 143).[3]

(*b*) *Compression Test Specimens.*—Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field (A.S.T.M. Designation: C 31),[3] except that Section 7 (*c*) of Method C 31 shall not apply to specimens used as a basis for acceptance.

(*c*) *Compression Tests.*—Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39).[3]

(*d*) *Flexure Tests.*—Standard Method of Test for Flexural Strength of Concrete (Laboratory Method Using Simple Beam with Third-Point Loading) (A.S.T.M. Designation: C 78).[3]

(*e*) *Core Tests.*—Standard Methods of Securing, Preparing, and Testing Specimens from Hardened Concrete for Compressive and Flexural Strengths (A.S.T.M. Designation: C 42).[3]

(*f*) *Yield.*—Standard Method of Test for Weight per Cubic Foot, Yield, and Air Content (Gravimetric) of Concrete (A.S.T.M. Designation: C 138).[3]

(*g*) *Cement Content of Hardened Concrete.*—Standard Method of Test for Cement Content of Hardened Portland-Cement Concrete (A.S.T.M. Designation: C 85).[3]

Standard Methods of

SECURING, PREPARING, AND TESTING SPECIMENS FROM HARDENED CONCRETE FOR COMPRESSIVE AND FLEXURAL STRENGTHS[1]

A.S.T.M. Designation: C 42 - 44

ADOPTED, 1927; REVISED, 1931, 1939, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 42; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover the procedure for securing, preparing, and testing specimens of hardened concrete from structures and pavements.

Precautions

2. A specimen to be tested for strength shall not be removed from the structure until the concrete has become hard enough to permit its removal without disturbing the bond between the mortar and the coarse aggregate. In general, the concrete shall be 14 days old before the specimens are removed. Specimens that show abnormal defects or that have been damaged in removal shall not be used.

Apparatus

3. (*a*) *Core Drill.*—A core drill shall be used for securing cylindrical core specimens. For specimens taken perpendicular to a horizontal surface, a shot drill is satisfactory; for specimens taken perpendicular to a vertical surface, a diamond drill shall be used.

(*b*) *Saw.*—A saw shall be used for securing beam specimens from the structure or pavement for flexural strength tests. The saw shall have a diamond or silicon carbide cutting edge and shall have adjustments that will permit cutting specimens which conform to the dimensions prescribed in Section 4(*b*).

Test Specimens

4. (*a*) *Core Specimens.*—A core specimen for the determination of pavement thickness shall have a diameter of at least 4 in. A core specimen for the determination of compressive strength shall have a diameter at least three times the maximum nominal size of the coarse aggregate used in the concrete, and in no case shall the diameter of the specimen be less than twice the maximum nominal size of the coarse aggregate. The length of the specimen, when capped, shall be as nearly as practicable twice its diameter.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard these methods were published as tentative from 1921 to 1927, being revised in 1925 and 1927.

(*b*) *Beam Specimens.*—A beam specimen for the determination of flexural strength, in general, shall have a cross-section of 6 by 6 in. (Note). The specimen shall be at least 21 in. in length, but when two tests for flexural strength are desired for one beam specimen it shall be at least 33 in. in length.

NOTE.—In many cases, particularly with prisms cut from pavement slabs, the width will be governed by the size of the coarse aggregate and the depth by the thickness of the slab.

Procedure

5. (*a*) *Core Drilling.*—A core specimen taken perpendicular to a horizontal surface shall be located, when possible, so that its axis is perpendicular to the bed of the concrete as originally placed. A specimen taken perpendicular to a vertical surface, or perpendicular to a surface with a batter, shall be taken from near the middle of a unit of deposit.

(*b*) *Slab Removal.*—A sufficiently large slab shall be removed so that the desired test specimens may be secured without the inclusion of any concrete which has been cracked, spalled, undercut, or otherwise damaged.

(*c*) *Beam Sawing.*—The sawing operation shall be so performed that the concrete will not be weakened by shock or by heating. The sawed surfaces shall be smooth, plane, parallel, and free from steps, ridges and grooves. Care shall be taken in handling sawed beam specimens to avoid chipping or cracking.

Length of Drilled Core Specimens

6. The lengths of core specimens for determining the thickness of the pavement shall be measured as prescribed in the Standard Method of Measuring Length of Drilled Concrete Cores (A.S.T.M. Designation: C 174).[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Compressive Strength

7. (*a*) *End Preparation.*—Core specimens to be tested in compression shall have ends that are essentially smooth, perpendicular to the axis, and of the same diameter as the body of the specimen. The ends of specimens which have projections of $\frac{1}{4}$ in. or more above the normal plane, or which depart from perpendicularity to the axis by more than 5 deg., or whose diameter departs from the mean by more than $\frac{1}{8}$ in. shall be sawed or tooled until they conform to these tolerances.

(*b*) *Moisture Conditioning.*—Test specimens shall be completely submerged in water at room temperature for 40 to 48 hr. immediately prior to the compression test. Specimens shall be tested promptly after removal from water storage. During the period between removal from the water storage and testing, the specimens shall be kept moist by covering with a wet burlap or blanket. They shall be tested in a moist condition.

(*c*) *Capping.*—Before making the compression test, the ends of the specimen shall be capped or ground. The capped or ground surface shall be at right angles to the axis of the specimen and shall not depart from a plane by more than 0.001 in. Caps shall be made as thin as practicable and shall not flow or fracture when the specimen is tested.

NOTE.—Neat portland or alumina cement and suitable mixtures of sulfur with granular materials are recognized as suitable for capping hardened concrete specimens. Sulfur caps should be allowed to harden for at least 1 hr. before applying load; cement caps for a sufficient period to comply with the requirements prescribed in Paragraph (*c*).

(*d*) *Measurement.*—Prior to testing, the length of the capped specimen shall be measured to the nearest 0.1 in. and its average diameter determined to the nearest 0.1 in. from two measurements taken at right angles near the center of the length.

(*e*) *Testing.*—Specimens shall be tested as prescribed in Section 4 of the Standard Method of Test for Compressive Strength of Molded Concrete Cylinders (A.S.T.M. Designation: C 39).[3]

(*f*) *Calculation and Report.*—The direction of the application of the load with reference to direction of compaction of the concrete in the structure shall be reported. The compressive strength of each specimen shall be calculated in pounds per square inch based on the average diameter of the specimen. If the ratio of length to diameter of a specimen is appreciably less than two, allowance for the ratio of length to diameter shall be made by multiplying the compressive strength by the applicable correction factor given in the following table. Values not given in the table shall be determined by interpolation:

Ratio of Length of Cylinder to Diameter $\left(\frac{l}{d}\right)$	Strength Correction Factor
1.75	0.98
1.50	0.96
1.25	0.94
1.10	0.90
1.00	0.85
0.75	0.70
0.50	0.50

Flexural Strength

8. (*a*) *Moisture Conditioning.*—Test specimens shall be completely submerged in water at room temperature for 40 to 48 hr. immediately prior to the flexure test. Specimens shall be tested promptly after removal from water storage. During the period between removal from the water storage and testing, the specimens shall be kept moist by covering with a wet burlap or blanket. They shall be tested in a moist condition.

(*b*) *Testing.*—Specimens shall be tested as prescribed in the Standard Method of Test for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading) (A.S.T.M. Designation: C 78).[3]

NOTE.—The compressive strengths of portions of beams broken in flexure may be determined by testing such portions as modified cubes using the procedure prescribed in the Standard Method of Test for Compressive Strength of Concrete Using Portions of Beams Broken in Flexure (Modified Cube Method) (A.S.T.M. Designation: C 116).[3]

Standard Method of

SAMPLING FRESH CONCRETE[1]

A.S.T.M. Designation: C 172 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 172; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for obtaining samples of fresh concrete from mixers, hoppers, or transportation units.

Size of Sample

2. The sample shall be representative of the batch. Where feasible, it shall consist of portions from different points in the batch. The composite sample shall consist of not less than 1 cu. ft. when the sample is to be used for acceptance tests. Smaller samples may be permitted for routine slump tests.

Procedure for Sampling

3. (*a*) *From Mixers Used in Construction, Other than Paving or Truck Mixers.*—The sample shall be obtained by passing a receptacle or receptacles through the discharge stream of the mixer at about the middle of the batch. Care shall be taken not to restrict the flow from the mixer in such a manner as to cause the concrete to segregate.

(*b*) *From Paving Mixers.*—The contents of the paving mixer shall be discharged upon the subgrade and the sample shall be collected from a sufficient number of points in the batch to be representative.

(*c*) *From Revolving Drum Truck Mixers or Agitators.*—The sample shall be taken in three or more regular increments throughout the discharge of the entire batch. To permit sampling, the rate of discharge of the batch shall be regulated by the rate of revolution of the drum and not by the size of the gate opening.

(*d*) *From Open-Top Truck Mixers and Agitators.*—The sample shall be taken directly from the mixer and shall consist of portions from not less than three points in the batch.

(*e*) *From Receiving Hoppers, Buckets, etc.*—Samples shall be taken by whichever of the procedures described in Paragraphs (*a*), (*b*), or (*c*) is most applicable under the conditions.

Mixing Composite Sample

4. The composite sample shall be mixed with a shovel sufficiently to insure homogeneity and immediately molded into test specimens.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1942 to 1944.

Standard Method of Test for

CEMENT CONTENT OF HARDENED PORTLAND-CEMENT CONCRETE[1]

A.S.T.M. Designation: C 85 - 42

ADOPTED, 1936; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 85; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test for determining the cement content of concrete is applicable to hardened portland-cement concretes *except those containing certain aggregates or admixtures which liberate soluble silica under the conditions of the test, such as slag, diatomites, and sodium silicate.*

Reagents

2. (*a*) *Hydrochloric Acid (approximately 3.3 N).*—Add 200 ml. of HCl (sp. gr. 1.19) to 600 ml. of distilled water.

(*b*) *Sodium Hydroxide (approximately 1 N).*—Dissolve 20 g. of NaOH in 200 ml. of water and dilute to a volume of 500 ml.

(*c*) *Hydrofluoric Acid (40 per cent).*

(*d*) *Sulfuric Acid (sp. gr. 1.84).*

Preparation of Sample

3. Every precaution shall be taken to have the sample of concrete used for analysis truly representative of the material under consideration. Several portions weighing at least 10 lb. each shall be taken to avoid all but slight inequalities of the concrete mix. These portions shall then be broken up, crushed in a suitable machine to about $\frac{1}{2}$ in. in size, and reduced to a fineness of approximately 150 to 200-mesh in a ball mill, disk pulverizer, or other device. Care shall be taken that the finer fractions of the broken sample, which are richer in cement, are not discarded or lost. After thorough mixing and quartering, a portion approximating 100 g. shall be taken and carefully freed, by means of a strong magnet, from particles of metallic iron abraded from the pulverizer or ball mill. The clean sample then shall be dried at 105 C. for at least 2 hr.

Procedure

4. (*a*) Weigh into each of three 250-ml. beakers, not less than a 2-g. portion

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1931 to 1936.

of the prepared sample. Moisten with a stream of hot water, while stirring to prevent adhesion to the beaker or the formation of lumps in the mass. Slowly add 100 ml. of 3.3 *N* HCl and stir thoroughly. The lumps which tend to form should be reduced with the glass rod. After the evolution of CO_2 has ceased and the reaction is apparently complete, heat gently for a few minutes and allow the contents of the beaker to settle. Decant through an ignited and weighed Gooch crucible which contains a mat of short asbestos shreds, practically insoluble in HCl, thick enough to be opaque to light. Once the filtration has begun, care shall be taken so that the mat and accumulated residue do not dry out completely until the filtration process is complete. Regulate the suction so as to maintain a rapid rate of dropping during the greater part of the filtration. Retain as much of the residue in the beaker as possible. Wash by decantation twice with hot water. Add 75 ml. of 1 *N* NaOH to the residue while stirring and heat to about 75 C. Decant as before and wash twice with hot water. Transfer the residue to the crucible and wash with at least 60 ml. of hot water.

(*b*) The filtrate now contains the silica in the form of silicic acid either in true solution or in suspension in the hydrochloric acid medium. If the aggregates of the original sample are largely calcareous or dolomitic, add 10 ml. of HCl (sp. gr. 1.19) to the solution. Transfer to a suitable beaker, with several rinsings of the filter flask. Evaporate to dryness with great care to minimize spattering, bake at not over 120 C. for 1 hr., moisten with HCl, (sp. gr. 1.19), evaporate and bake again, and take up for filtration in 75 ml. of 2 to 3 *N* HCl heated to boiling. Filter through an ashless filter-paper, and wash the residue with 50 ml. of hot 1 *N* HCl and then with hot water until the washings are free from chlorides. Repeat the evaporation and filtering processes to recover the small amounts of silica dissolved and add these to the first residue. Determine the silica present in the sample by treatment with HF and H_2SO_4 in accordance with the procedure given in Section 8 of the Standard Methods of Chemical Analysis of Portland Cement (A.S.T.M. Designation: C 114) of the American Society for Testing Materials.[3]

Correction Factor

5. When the aggregates are available that were used in the concrete being analyzed, a blank test shall be run on these aggregates to determine their content of silica, soluble under the conditions of the test (Section 4). This content of soluble silica shall then be used as a correction factor and be subtracted from the total soluble silica found in the concrete, the difference being due to the cement contained in the specimen.

Calculation

6. The percentage of cement in the sample shall be calculated by dividing the percentage of silica found by the factor 0.2175,[4] provided it is not known that the silica content of the cement differs from this value. When possible, the *known value* shall be taken as the factor.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] For the correctness of this factor as an average silica content of American cements, see Report of Subcommittee I on Definitions and Chemical Limitations, of Committee C-1 on Cement, *Proceedings*, Am. Soc. Testing Mats., Vol. 28, Part I, pp. 238 to 243 (1928).

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 23

Standard Method of

MAKING AND CURING CONCRETE COMPRESSION AND FLEXURE TEST SPECIMENS IN THE FIELD[1]

A.S.T.M. Designation: C 31 – 44

ADOPTED, 1921; REVISED, 1927, 1931, 1933, 1938, 1939, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 31; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for making and curing compression and flexure test specimens of concrete sampled from concrete being used in construction.

NOTE.—For the method of making and curing concrete specimens in the laboratory see the Tentative Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Laboratory (A.S.T.M. Designation: C 192).[3]

Sampling of Concrete

2. Samples of concrete for test specimens shall be taken in accordance with the Standard Method of Sampling Fresh Concrete (A.S.T.M. Designation: C 172).[3] The location in the work of the batch of concrete thus sampled shall be noted for further reference.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1920 to 1921.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

COMPRESSION TEST SPECIMENS

Size of Specimens

3. Compression test specimens shall be cylindrical with a length equal to twice the diameter. Standard cylindrical specimens shall be 6 in. in diameter by 12 in. in length if the coarse aggregate does not exceed 2 in. in nominal size. Smaller test specimens shall have a ratio of diameter of specimen to maximum size aggregate of not less than 3 to 1, except that the diameter of the specimen shall not be less than 3 in. for mixtures containing aggregate more than 5 per cent of which is retained on a No. 4 (4760-micron) sieve. For concrete containing aggregate larger than 2 in., the cylindrical specimens shall have a diameter at least three times the maximum nominal size of aggregate. The oversize of any nominal size aggregate used shall not exceed the requirements prescribed in the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33).[3]

Molds

4. Molds for compression test specimens shall be cylindrical in form, made of

nonabsorbent material, and shall be substantial enough to hold their form during the molding of test specimens. They shall not vary from the standard diameter by more than $\frac{1}{16}$ in. nor from the standard length by more than $\frac{1}{4}$ in. Metal molds shall each be provided with a machined metal base plate and means shall be provided for securing the base plate to the mold. The assembled mold and base plate shall be watertight and shall be oiled with mineral oil before use. Molds made of material other than metal shall be provided with a base plate or bottom. Assembled molds of any type shall be watertight.

NOTE.—Satisfactory molds may be made from cold-drawn, seamless steel tubing or from steel pipe machined on the inside. These tubular sections shall be cut to the proper length, split along one element and fitted with a circumferential metal band and bolt for closing. Satisfactory molds may also be made from iron or steel castings. In general, molds made from formed sheet metal are not satisfactory. Paraffined cardboard molds will give good results under expert supervision.

Molding Specimens

5. The test specimens shall be formed by placing the concrete in the mold in three layers of approximately equal volume. In placing each scoopful of concrete, the scoop shall be moved around the top edge of the mold as the concrete slides from it in order to insure a symmetrical distribution of the concrete within the mold. The concrete shall be further distributed by a circular motion of the tamping rod. Each layer shall be rodded with 25 strokes of a tamping rod $\frac{5}{8}$ in. in diameter and approximately 24 in. in length, bullet-shaped at the lower end. The strokes shall be distributed uniformly over the cross-section of the mold and shall penetrate into the underlying layer. The bottom layer shall be rodded throughout its depth. After the top layer has been rodded, the surface of the concrete shall be struck off with a trowel and covered with a glass or metal plate to prevent evaporation.

Capping Specimens

6. (*a*) If metal molds are used, the test specimens may be capped with a thin layer of stiff, neat-cement paste after the concrete has ceased settling in the molds, generally from 2 to 4 hr. or more after molding. The cap shall be formed by means of a piece of plate glass not less than $\frac{1}{4}$ in. in thickness or a machined metal plate not less than $\frac{1}{2}$ in. in thickness and having a minimum surface dimension at least 1 in. larger than the diameter of the mold. The plate shall be worked on the cement paste until its lower surface rests on top of the mold. The cement for capping shall be mixed to a stiff paste 2 to 4 hr. before it is to be used in order to avoid the tendency of the cap to shrink. Adhesion of the concrete to the top and bottom plates may be avoided by coating them with oil or grease.

(*b*) Specimens not capped with neat-cement paste as described in Paragraph (*a*) shall be ground or capped before testing. In all cases the capped or ground surface shall not depart from a plane by more than 0.001 in. and shall be at right angles to the axis of the specimen. Caps shall be made as thin as practicable and shall not flow or fracture when the specimen is tested.

NOTE.—Neat portland or alumina cement and suitable mixtures of sulfur with granular materials are recognized as suitable for capping hardened concrete specimens. Sulfur caps should be allowed to harden for at least 1 hr. before applying load; cement caps for a sufficient period to comply with the requirements prescribed in Paragraph (*b*).

Curing Specimens

7. (*a*) During the first 24 hr. all test specimens shall be kept in a storage box (Note 1) so constructed and located on the

work that its air temperature when containing concrete specimens will remain within 60 to 80 F. (16 to 27C.), or other suitable means shall be used that provide similar temperature conditions.

NOTE 1.—It is suggested that the storage box be made of 1-in. dressed tongue-and-groove lumber, well braced with battens to avoid warping. The box should be well painted inside and outside and should be provided with a hinged cover and padlock.

(*b*) Test specimens made to check the adequacy of the laboratory design for strength of the concrete, or as the basis for acceptance, shall be removed from the molds at the end of 24 hr. and stored in a moist condition (Note 2) at a temperature within the range of 65 to 75 F. (18 to 24 C.) (Note 3) until the time of test. Specimens shall not be exposed to a stream of running water. If storage in water is desired, a saturated lime solution shall be used.

NOTE 2.—Moist condition is that in which free water is maintained on the surfaces of the specimens at all times.

NOTE 3.—Attention is directed to the fact that the temperature within damp sand and under wet burlap or similar materials will always be lower than the temperature in the surrounding atmosphere if evaporation takes place.

(*c*) Test specimens for determining when a structure may be put into service shall be removed from the molds at the end of 24 hr. and stored in the structure as near to the point of sampling as possible and shall receive, in so far as practicable, the same protection from the elements on all surfaces as is given to the portions of the structure which they represent. Field control specimens shall be protected from injury while on the work. For 28-day tests the specimens shall be sent to the laboratory not more than 7 days prior to the time of test. For other periods of test the specimens shall be kept in the field at least three fourths of the test period. While in the laboratory the specimens shall be kept at laboratory temperature until 24 to 48 hr. before testing, during which final period they shall be immersed in water at laboratory temperature.

FLEXURE TEST SPECIMENS

Size of Specimens

8. The cross-section of the flexure test specimen shall be 6 by 6 in. if the coarse aggregate does not exceed 2 in. in nominal size. For larger coarse aggregate, the minimum cross-sectional dimension shall be not less than three times the maximum nominal size of the coarse aggregate. The oversize of any nominal size used shall not exceed the requirements prescribed in the Standard Specifications for Concrete Aggregates (A.S.T.M. Designation: C 33).[3]

Molds

9. Molds for flexure test specimens shall be rigid and nonabsorptive and shall be at least 3 in. longer than the required span length as prescribed in Section 3 of the Standard Method of Test for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading) (A.S.T.M. Designation: C 78).[3] Means shall be provided for securing the base plate to the mold. The assembled mold and base plate shall be watertight and shall be lightly oiled with a mineral oil before use.

Molding Specimens

10. The test specimen shall be formed with its long axis horizontal. The concrete shall be placed in layers approximately 3 in. in depth and each layer shall be rodded 50 times for each square foot of area. The top layer shall slightly overfill the mold. After each layer is rodded, the concrete shall be spaded along the sides and ends with a mason's trowel or other suitable tool. When the rodding

and spading operations are completed, the top shall be struck off with a straightedge and finished with a wood float. The test specimen shall be made promptly and without interruption.

Curing Specimens

11. (*a*) Test specimens made to check the adequacy of the laboratory design for strength of the concrete, or as the basis for acceptance, shall be covered immediately after molding with a double layer of wet burlap which shall be kept wet until the specimens are removed from the molds. During the first 24 hr. the specimens shall be cured under the conditions specified in Section 7 (*a*). At the end of the 24-hr. period the specimens shall be removed from the molds and stored in a moist condition as specified in Section 7 (*b*).

(*b*) Test specimens for determining when a structure may be put into service, shall be cured as nearly as practicable, in the same manner as the concrete in the structure. At the end of 24 hr. the specimens shall be taken in the molds to a location preferably near a field laboratory, removed from the molds and stored by placing them on the ground as molded, with their top surfaces up. The sides and ends of the specimens shall then be banked with damp earth or sand which shall be kept damp, leaving the top surfaces exposed to the specified curing treatment. At the end of the curing period the specimens shall be left in place with the top surfaces exposed to the weather in the same manner as the structure. Specimens shall be tested in the moist condition resulting from the specified curing treatment.

Standard Method of Test for

COMPRESSIVE STRENGTH OF MOLDED CONCRETE CYLINDERS[1]

A.S.T.M. Designation: C 39 - 44

ADOPTED, 1925; REVISED, 1927, 1933, 1939, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 39; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for compression tests of molded concrete cylinders.

NOTE.—For methods of molding concrete specimens see the Tentative Method of Making and Curing Concrete Compression and Flexure Specimens in the Laboratory (A.S.T.M. Designation: C 192),[3] and the Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field (A.S.T.M. Designation: C 31).[3]

Apparatus

2. The testing machine may be of any type of sufficient capacity which will provide the rate of loading prescribed in Section 4 (*b*). It shall conform to the requirements of Section 27 of the Standard Methods of Verification of Testing Machines (A.S.T.M. Designation: E 4).[3] The testing machine shall be equipped with two steel bearing blocks with hardened faces (Note) one of which is a spherically seated block that normally will bear on the upper surface of the specimen, and the other a plain rigid block on which the specimen will rest. The bearing faces shall be at least as large and preferably slightly larger than the surface of the specimen to which the load is applied. The bearing faces, when new, shall not depart from a plane by more than 0.0005 in. at any point, and they shall be maintained within a permissible variation limit of 0.001 in. In the spherically seated block the diameter of the sphere shall not greatly exceed the diameter of the specimen and the center of the sphere shall coincide with the center of the bearing face. The movable portion of this block shall be held closely in the spherical seat, but the design shall be such that the bearing face can be rotated freely and tilted through small angles in any direction.

NOTE.—It is desirable that the bearing faces of blocks used for compression testing of concrete have a Rockwell hardness of not less than C 60.

Test Specimens

3. Compression tests of moist cured specimens shall be made as soon as practicable after removal from the curing room. Test specimens, during the pe-

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1921 to 1925.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

riod between their removal from the moist room and testing shall be kept moist by a wet burlap or blanket covering. They shall be tested in a moist condition. The diameter of the test specimen shall be determined to the nearest 0.01 in. by averaging two diameters measured at right angles to each other near the center of the length of the specimen. This average diameter shall be used for calculating the cross-sectional area. The length of the specimen including caps shall be measured to the nearest 0.1 in.

Procedure

4. (*a*) *Placing the Specimen.*—The plain (lower) bearing block shall be placed, with its hardened face up, on the table or platen of the testing machine directly under the spherically seated (upper) bearing block. The bearing face shall be wiped clean and the test specimen placed on it. The axis of the specimen shall be carefully aligned with the center of thrust of the spherically seated block. As the spherically seated block is brought to bear on the specimen its movable portion shall be rotated gently by hand so that uniform seating is obtained.

(*b*) *Rate of Loading.*—The load shall be applied continuously and without shock. In testing machines of the screw type the moving head shall travel at a rate of about 0.05 in. per min. when the machine is running idle. In hydraulically operated machines the load shall be applied at a constant rate within the range 20 to 50 psi. per sec. During the application of the first half of the maximum load a higher rate of loading shall be permitted.

(*c*) The load shall be increased until the specimen fails and the maximum load carried by the specimen during the test shall be recorded. The type of failure and the appearance of the concrete shall be noted.

Calculation

5. The compressive strength of the specimen shall be calculated by dividing the maximum load carried by the specimen during the test by the average cross-sectional area determined as described in Section 3, and shall be expressed to the nearest 10 psi.

Report

6. The report shall include the following:

(*1*) Identification number,

(*2*) Diameter (and length, if not standard), in inches,

(*3*) Cross-sectional area, in square inches,

(*4*) Maximum load, in pounds,

(*5*) Compressive strength calculated to the nearest 10 psi.,

(*6*) Type of fracture, if other than the usual cone,

(*7*) Defects in either specimen or caps,

(*8*) Age of specimen.

Standard Method of Test for

COMPRESSIVE STRENGTH OF CONCRETE USING PORTIONS OF BEAMS BROKEN IN FLEXURE[1]

MODIFIED CUBE METHOD

A.S.T.M. Designation: C 116 - 44

ADOPTED, 1936; REVISED, 1939, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 116; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the compressive strength of concrete, using for the test specimens portions of beams broken in flexure.

NOTE.—For the method of making the flexural strength test, see the Standard Method of Test for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading) (A.S.T.M. Designation: C 78).[3]

Test Specimens

2. The broken portions of beams selected for the compression test shall have a length not less than 2 in. greater than the depth of the beam and shall be free from cracks, chipped surfaces, or other obvious defects.

Preparation of Test Specimen

3. (*a*) The top and bottom of the beam shall be ground or capped in such a manner that plane surfaces are secured. The caps shall cover the full width of the beam and shall be of such length as to permit the adjustment of the bearing plates for the test so that the upper bearing plate may be placed directly over the lower bearing plate. The material used for capping and the thickness of the cap shall be such that it will not flow or fracture under the load.

NOTE.—Neat portland or alumina cement and suitable mixtures of sulfur with granular materials are recognized as suitable for capping hardened concrete specimens. Sulfur caps should be allowed to harden for at least 1 hr. before applying load; cement caps for a sufficient period to comply with the requirements prescribed in Paragraph (*a*).

(*b*) During the interval between testing of specimens as beams and testing the broken portions as cubes, the specimens shall be kept moist by storage in a moist closet or under wet burlap.

Procedure

4. (*a*) Only the ultimate compressive

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1936.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

strength shall be determined. The specimen shall be tested between machined metal bearing plates not less than $\frac{3}{4}$ in. in thickness. The diameter of the spherical bearing block shall be at least 75 per cent of the depth of the beam. The plates shall be of such dimensions that the contact faces shall be substantially square and shall have the same dimensions as the nominal width of the beam tested. The upper bearing plate shall be placed directly over the lower plate. A device that insures the proper location of the upper plate with reference to the lower plate is shown in Fig. 1. The load shall be applied to the bearing blocks by means of an adjustable head.

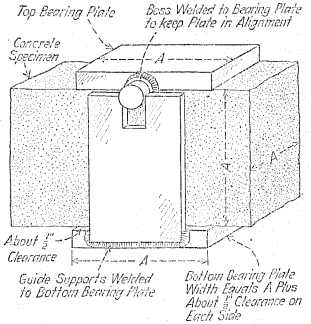

FIG. 1.—Device for Aligning Bearing Plates.

(*b*) *Application of Load.*—The load shall be applied without shock. The moving head of the screw type of testing machine shall travel at the rate of about 0.05 in. per min. when the machine is running idle. In hydraulic machines the loading shall be adjusted to a constant rate within the limits of 35 ± 15 psi. per sec.

Calculation and Report

5. The total load indicated by the testing machine at failure of the test specimen shall be recorded and the unit compressive strength calculated in pounds per square inch, taking as the cross-sectional area the average of the upper and lower contact areas. The type of failure and appearance of the concrete shall be noted.

Standard Method of Test for

FLOW OF PORTLAND-CEMENT CONCRETE BY USE OF THE FLOW TABLE[1]

A.S.T.M. Designation: C 124 – 39

ADOPTED, 1938; REVISED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 124; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method is intended for determining the flow of concrete.

Apparatus

2. (*a*) *Mold.*—The mold shall be made of a smooth metal casting in the form of the frustum of a cone with a base 10 in. in diameter, upper surface $6\frac{3}{4}$ in. in diameter, and altitude 5 in.; the base and the top shall be open and at right angles to the axis of the cone. The mold shall be provided with handles. (See Fig. 1.)

(*b*) *Flow Table.*—The flow table shall conform to the design shown in Fig. 2 and shall be mounted on and bolted to a concrete base having a height of 15 to 20 in. and weighing not less than 300 lb.

Sample

3. Samples of concrete for test specimens shall be taken at the mixer, or in the case of ready-mixed concrete, from the transportation vehicle during discharge. The sample of concrete from which test specimens are made shall be representative of the entire batch. Such samples shall be obtained by repeatedly passing a scoop or pail through the discharging stream of concrete, starting the sampling operation at the beginning of discharge, and repeating the operation until the entire batch is discharged. The sample thus obtained shall be transported to the place of molding of the specimen, and to counteract segregation the concrete shall be mixed with a shovel until it is uniform in appearance. The location in the work of the batch of concrete thus sampled shall be noted for future reference. In the case of paving concrete, samples may be taken from the batch immediately after depositing on the subgrade. At least five samples shall be taken from different portions of the pile, and these samples shall be thoroughly mixed to form the test specimen.

Procedure

4. Immediately preceding the test, the table top shall be wetted and cleaned of all gritty material and the excess

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1938.

water removed with a rubber squeegee. The mold, centered on the table, shall be firmly held in place and filled in two layers, each approximately one-half the volume of the mold. Each layer shall be rodded with 25 strokes of a round, nonmetallic rod $\frac{5}{8}$ in. in diameter and 24 in. in length, having a bullet-pointed end. The strokes shall be distributed in a uniform manner over the cross-section of the mold and shall penetrate into the underlying layer. The bottom layer shall be rodded throughout its depth. After the top layer has been rodded, the surface of the concrete shall be struck off with a trowel so that the mold is exactly filled. The excess concrete which has overflowed the mold shall be removed and the area of the table outside of the mold again cleaned. The mold shall be immediately removed from the concrete by a steady, upward pull. The table shall then be raised and dropped $\frac{1}{2}$ in., 15 times in about 15 sec. The diameter of the spread concrete shall be the average of six symmetrically distributed caliper measurements read to the nearest $\frac{1}{4}$ in.

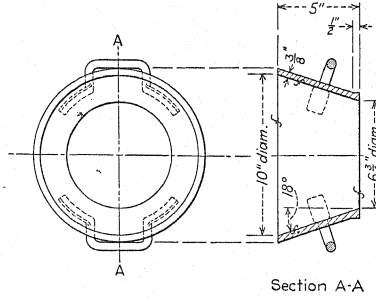

FIG. 1.—Mold for Flow Test.

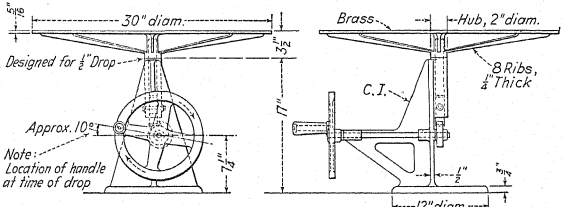

FIG 2.—Flow Table Assembly.

Flow

5. The flow of the concrete shall be recorded as the percentage increase in diameter of the spread concrete over the base diameter of the molded concrete, calculated from the following formula:

$$\text{Flow, per cent} = \frac{\text{spread diameter} - 10 \text{ in.}}{10} \times 100$$

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 119-42

Standard Method of

SLUMP TEST FOR CONSISTENCY OF PORTLAND-CEMENT CONCRETE[1]

A.S.T.M. Designation: C 143 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 143; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure to be used both in the laboratory and in the field for determining consistency of concrete.[3]

Apparatus

2. The test specimen shall be formed in a mold of No. 16 gage galvanized metal in the form of the lateral surface of the frustrum of a cone with the base 8 in. in diameter, the top 4 in. in diameter, and the altitude 12 in. The base and the top shall be open and parallel to each other and at right angles to the axis of the cone. The mold shall be provided with foot pieces and handles as shown in Fig. 1.

Sample

3. Samples of concrete for test specimens shall be taken at the mixer or, in the case of ready-mixed concrete, from the transportation vehicle during discharge. The sample of concrete from which test specimens are made shall be representative of the entire batch. Such samples shall be obtained by repeatedly passing a scoop or pail through the discharging stream of concrete, starting the sampling operation at the beginning of discharge and repeating the operation until the entire batch is discharged. The sample thus obtained shall be transported to the place of molding of the specimen, and to counteract segregation the concrete shall be mixed with a shovel until it is uniform in appearance. The location in the work of the batch of concrete thus sampled shall be noted for future reference. In the case of paving concrete, samples may be taken from the batch immediately after depositing on the subgrade. At least five samples shall be taken from different portions of the pile and these samples shall be

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1922 to 1939, being revised in 1925, 1926, 1932, and 1939. This method was formerly published under the jurisdiction of A.S.T.M. Committee D-4 on Road and Paving Materials and was designated D 138; but it was transferred in 1939 to Committee C-9 and redesignated C 143.

[3] This test is not considered applicable when there is a considerable amount of coarse aggregate over 2 in. in size in the concrete. The committee is now working on a method suitable for determining the consistency of concrete using aggregate over 2 in. in size.

thoroughly mixed to form the test specimen.

Procedure

4. The mold shall be dampened and placed on a flat, moist, nonabsorbent surface. From the sample of concrete obtained as described in Section 3, the mold shall immediately be filled in three layers, each approximately one-third the volume of the mold. In placing each scoopful of concrete the scoop shall be moved around the top edge of the mold as the concrete slides from it, in order to insure symmetrical distribution of concrete within the mold. Each layer shall be rodded with 25 strokes of a $\frac{5}{8}$-in. rod, 24 in. in length, bullet pointed at the lower end. The strokes shall be distributed in a uniform manner over the cross-section of the mold and shall penetrate into the underlying layer. The bottom layer shall be rodded throughout its depth. After the top layer has been rodded, the surface of the concrete shall be struck off with a trowel so that the mold is exactly filled. The mold shall be immediately removed from the concrete by raising it carefully in a vertical direction. The slump shall then be measured immediately by determining the difference between the height of the mold and the height at the vertical axis of the specimen.

Slump

5. The consistency shall be recorded in terms of inches of subsidence of the specimen during the test, which shall be known as the slump:

Slump = 12 — inches of height after subsidence

NOTE.—After the slump measurement is completed, the side of the concrete frustrum

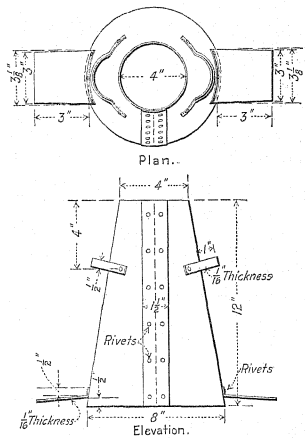

FIG. 1.—Mold for Slump Test.

should be tapped gently with the tamping rod. The behavior of the concrete under this treatment is a valuable indication of the cohesiveness, workability, and placeability of the mix. A well proportioned workable mix will gradually slump to lower elevations and retain its original identity, while a poor mix will crumble, segregate, and fall apart.

Standard Method of

MEASURING LENGTH OF DRILLED CONCRETE CORES[1]

A.S.T.M. Designation: C 174 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 174; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for determining the length of a core drilled from a concrete structure, particularly from a concrete pavement.

Apparatus

2. (*a*) The apparatus shall be a calipering device that will measure the length of axial elements of the core. While the details of the mechanical design are not prescribed, the apparatus shall conform to the requirements of Paragraphs (*b*) to (*f*).[3]

(*b*) The apparatus shall be so designed that the specimen will be held with its axis in a vertical position by three symmetrically placed supports bearing against the lower end. These supports shall be short posts or studs of hardened steel, and the ends that bear against the surface of the specimen shall be rounded to a radius of not less than $\frac{1}{4}$ in. and not more than $\frac{1}{2}$ in.

(*c*) The apparatus shall provide for the accommodation of specimens of different nominal lengths over a range of at least 4 to 10 in.

(*d*) The calipering apparatus shall be so designed that it will be possible to make a length measurement at the center of the upper end of the specimen and at eight additional points spaced at equal intervals along the circumference of a circle whose center point coincides with that of the end area of the specimen and whose radius shall not exceed the radius of the specimen less $1\frac{1}{2}$ in.

(*e*) The measuring rod or other device that makes contact with the end surface of the specimen for measurement shall be rounded to a radius of $\frac{1}{8}$ in. The scale on which the length readings are made shall be marked with clear, definite, accurately spaced graduations. The spacing of the graduations shall be 0.10 in. or a decimal part thereof.

(*f*) The apparatus shall be stable and sufficiently rigid to maintain its shape and alignment without a distortion or deflection of more than 0.01 in. during all normal measuring operations.

---

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1942 to 1944.

[3] For further information relating to the development of this method and apparatus, reference should be made to the "Project Report on a Study of Methods of Measurement of the Length of Cores Drilled from Concrete Structures," prepared by L. W. Teller for Subcommittee VII on Methods and Apparatus for Testing Concrete, of Committee C-9, see *Proceedings*, Am. Soc. Testing Mats., Vol. 42 (1942).

Test Specimens

3. Cores used as specimens for length measurement shall be in every way representative of the concrete in the structure from which they are removed. The specimen shall be drilled with the axis normal to the surface of the structure, and the ends shall be free from all conditions not typical of the surfaces of the structure. Cores that show abnormal defects or that have been damaged appreciably in the drilling operation shall not be used.

Procedure

4. (*a*) Before any measurements of the core length are made, the apparatus shall be calibrated with suitable gages so that errors caused by mechanical imperfections in the apparatus are known. When these errors exceed 0.01 in., suitable corrections shall be applied to the core length measurements.

(*b*) The specimen shall be placed in the measuring apparatus with the smooth end of the core, that is, the end that represents the upper surface of a pavement slab or a formed surface in the case of other structures, placed down so as to bear against the three hardened-steel supports. The specimen shall be so placed on the supports that the central measuring position of the measuring apparatus is directly over the mid-point of the upper end of the specimen.

(*c*) Nine measurements of the length shall be made on each specimen, one at the central position and one each at eight additional positions spaced at equal intervals along the circumference of the circle of measurement described in Section 2 (*d*). Each of these nine measurements shall be read directly to tenths of inches and to hundredths of inches either directly or by estimation.

NOTE—If, in the course of the measuring operation, it is discovered that at one or more of the measuring points the surface of the specimen is not representative of the general plane of the core end because of a small projection or depression, the specimen shall be rotated slightly about its axis and a complete set of nine measurements made with the specimen in the new position.

Report

5. The individual observations shall be recorded to the nearest 0.01 in., and the average of the nine measurements expressed to the nearest 0.05 in. shall be reported as the length of the concrete core.

Standard Method of Test for

FLEXURAL STRENGTH OF CONCRETE (USING SIMPLE BEAM WITH THIRD-POINT LOADING)[1]

A.S.T.M. Designation: C 78 – 44

ADOPTED, 1938; REVISED, 1939, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 78; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the flexural strength of concrete by the use of a simple beam with third-point loading.

NOTE.—For methods of molding concrete specimens see the Tentative Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Laboratory (A.S.T.M. Designation: C 192),[3] and the Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field (A.S.T.M. Designation: C 31).[3]

Apparatus

2. The third-point loading method shall be used in making flexure tests of concrete employing bearing blocks which will insure that forces applied to the beam will be vertical only and applied without eccentricity. A diagram of an apparatus which accomplishes this purpose is shown in Fig. 1.

NOTE.—Sometimes nonstandard methods of load application are used in the field. If such methods are used, the results should be correlated with those obtained with standard methods. Apparatus for making flexure tests of concrete should be designed to incorporate the following principles:

(*1*) The distance between supports and points of load application should remain constant for a given apparatus.

(*2*) The load should be applied normal to the loaded surface of the beam and in such a manner as to avoid eccentricity of loading.

(*3*) The direction of the reactions should be parallel to the direction of the applied load at all times during the test.

(*4*) The load should be applied at a uniform rate and in such a manner as to avoid shock.

(*5*) The ratio of distance between point of load application and nearest reaction to the depth of the beam should be not less than one.

The directions of loads and reactions may be maintained parallel by judicious use of linkages, rocker bearings, and flexure plates. Eccentricity of loading can be avoided by use of spherical bearings.

Test Specimen

3. The test specimen shall have a span as nearly as practicable three times its depth as tested.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1930 to 1938, being revised in 1936.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

4. The test specimen shall be turned on its side with respect to its position as molded and centered on the bearing blocks. The load-applying blocks shall be brought in contact with the upper surface at the third points between the supports. If full contact is not obtained between the specimen and the load-applying blocks and the supports, due to the surfaces of the specimen being out of plane, the surfaces of the specimen, where they are in contact with the blocks or supports, shall be ground or capped (Note) to produce substantially full contact. The load may be applied rapidly up to approximately 50 per cent of the breaking load, after which it shall be applied at such a rate that the increase in extreme fiber stress does not exceed 150 psi. per min.

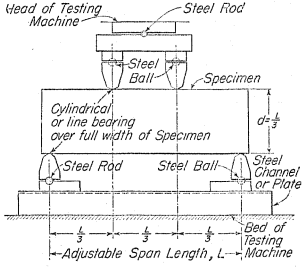

FIG. 1.—Diagrammatic View of Apparatus for Flexure Test of Concrete by Third-Point Loading Method.

NOTE.—Neat portland or alumina cement and suitable mixtures of sulfur with granular materials are recognized as suitable for capping hardened concrete specimens. Sulfur caps should be allowed to harden for at least 1 hr. before applying load, cement caps for a sufficient period to insure their resistance to cracking or flowing under the applied load.

Measurement of Specimens After Test

5. Measurements to the nearest 0.1 in. shall be made to determine the average width and average depth of the specimen at the section of failure.

Calculations

6. (*a*) If the fracture occurs within the middle third of the span length, the modulus of rupture shall be calculated as follows:

$$R = \frac{Pl}{bd^2}$$

where:

R = modulus of rupture in pounds per square inch,
P = maximum applied load indicated by the testing machine in pounds,
l = span length in inches,
b = average width of specimen in inches, and
d = average depth of specimen in inches.

NOTE.—Weight of the beam is not included in the above calculation.

(*b*) If the fracture occurs outside of the middle third of the span length by not more than 5 per cent of the span length, the modulus of rupture shall be calculated as follows:

$$R = \frac{3Pa}{bd^2}$$

where:

a = distance between line of fracture and the nearest support measured along the center line of the bottom surface of the beam, in inches.

(*c*) If the fracture occurs outside of the middle third of the span length by more than 5 per cent of the span length, the results of the test shall be discarded.

Report

7. The report shall include the following:

(*l*) Identification number,

(*2*) Average width to the nearest 0.1 in.,
(*3*) Average depth to the nearest 0.1 in.,
(*4*) Span length in inches,
(*5*) Maximum applied load in pounds,
(*6*) Modulus of rupture calculated to the nearest 5 psi.,
(*7*) Defects in specimen, and,
(*8*) Age of specimen.

Standard Method of Test for

VOLUME CHANGE OF CEMENT MORTAR AND CONCRETE[1]

A.S.T.M. Designation: C 157 - 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 157; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) This method of test is intended to provide a standardized procedure for determining the volume changes of cement mortar and concrete when a fairly simple, routine test is desired. It is not offered as a preferred research method or with the idea of limiting research on volume changes to a single restricted procedure. While this method is intended primarily for mixtures made with portland cement, it may also be used for testing those made with other types of cement.

(*b*) The term "volume change" is intended to apply to changes in dimension of the test specimen due to causes other than stress. The method is designed to measure volume changes due to chemical change, moisture change or similar causes, and it is intended that volume changes resulting from variations in temperature will be kept negligible. Volume change as measured and expressed in this method is reported as an increase or decrease in a *linear* dimension of the test specimen.

Apparatus

2. (*a*) *Molds for Mortar and Concrete Specimens.*—Molds for casting the prismatic test specimens shall be made of metal and so designed that the specimen will be cast with its longitudinal axis in a horizontal position. The molds shall be fitted with metal end plates that provide means for holding a stainless steel gage point (Note 1) in exact position at the center of each end of the specimen during the placing and hardening of the cement mortar or concrete. Details of a suitable mold (designed for mortar specimens) are shown in Fig. 1.

NOTE 1.—The device for holding the contact points shall be arranged so that it can be partially released after the mixture has been compacted into place in order to avoid restraint of the contact points during initial shrinkage of the specimen.

(*b*) *Measuring Apparatus.*—The apparatus for measuring volume change

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1943, being revised in 1943.

shall be of such design as to provide the following (Note 2):

(*1*) A positive means of contact with the specimen that will insure reproducible measurements of length,

(*2*) A high grade dial micrometer or other measuring device graduated to read in 0.0001-in. units, and accurate within 0.0001 in. in any 0.0010-in. range and 0.0002 in. in any 0.0100-in. range (Note 3),

(*3*) Sufficient range in the measuring device to allow for small variations in gage length of various specimens,

NOTE 3.—It is recommended that the micrometer or other measuring device be calibrated throughout its range to determine both the periodic and cumulative errors, so that proper corrections are applied to the observed data.

Test Specimens

3. (*a*) *Mortar Specimens.*—The test specimen for cement mortar shall be a prism 2 in. square and 11 in. in length.

(*b*) *Concrete Specimens.*—The test specimen for concrete shall be a prism 3 in. square and 11 in. in length.

(*c*) *Contact or Gage Points.*—Each test specimen shall have embedded at each end of the longitudinal axis, a stainless steel contact or gage point so designed as to provide an effective gage length of 10 ± 0.01 in.

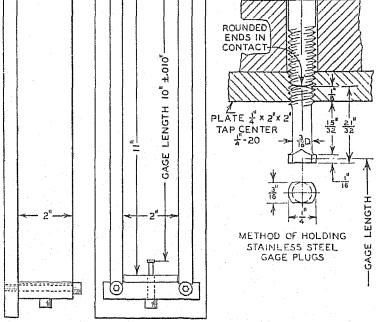

FIG. 1.—Mold for Horizontal Casting of Prismatic Cement Mortar Specimens.

(*4*) Means for checking the measuring device against a standard of reference at regular intervals, and

(*5*) Convenient and rapid measurement of specimens.

NOTE 2.—One type of apparatus that has satisfactorily met in service the requirements prescribed is shown in Fig. 2. In this apparatus the contact surfaces are provided by spherical ground ends on the contact points in the specimen and conical recesses in the terminals of the instrument.

Molding Specimens

4. (*a*) Prior to molding specimens, the inside surfaces of the molds shall be coated with a thin film of a mineral oil, petroleum jelly, or stearic acid paste.

Joints in molds may be sealed with hot paraffin or a mixture of paraffin and rosin.

(*b*) All materials shall be proportioned by weight. The mixing and molding procedure shall follow, as nearly as possible, those prescribed in the Standard Method of Test for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading) (A.S.T.M. Designation: C 78).[3]

Storage of Specimens

5. (*a*) Immediately after molding, the test specimens in the molds shall be covered with wet burlap or placed in the moist room. After 20 to 24 hr. (Note) the specimens shall be removed from the molds and placed in the storage room.

NOTE.—In the case of certain slow-hardening cements, it may be necessary to allow specimens to remain in the mold for more than 24 hr. in order to avoid damage during removal from the molds. When making tests in which such cements are included, the storage schedule may be modified but any specimens involved in the test program, which are to be used for comparison, shall be subjected to identical conditions of storage.

(*b*) The storage room shall be maintained at a temperature of 70 ± 2 F. and a relative humidity of 50 ± 5 per cent.

Procedure

6. The measuring apparatus shall be kept in the room in which the specimens are stored, and all measurements shall be made in the storage room, in order to avoid changes in temperature and humidity conditions surrounding the test specimens during length measurements.

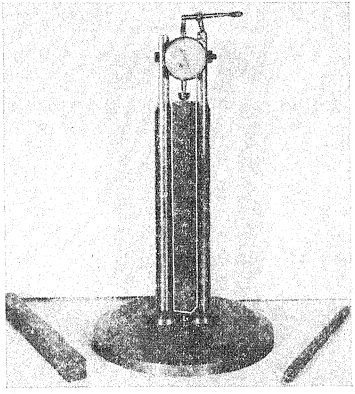

FIG. 2.—Type of Suitable Apparatus for Measurement of Volume Changes.

Report

7. The report shall include the following:

(*1*) Kind and proportions of materials used,

(*2*) Method of mixing the cement mortar or concrete,

(*3*) Method of molding specimens,

(*4*) Length of the period of preliminary moist curing and other storage conditions,

(5) Temperature and relative humidity of the storage room,

(6) Length of the period of observation, and

(7) Volume change data, recorded as expansion or contraction in inches per inch of the gage length of the test specimen.

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 121

Standard Method of Test for

WEIGHT PER CUBIC FOOT, YIELD, AND AIR CONTENT (GRAVIMETRIC) OF CONCRETE[1]

A.S.T.M. Designation: C 138 - 44

ADOPTED, 1939; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 138; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the weight per cubic foot of freshly mixed concrete and gives formulas for calculating: the volume of concrete produced from a mixture of known quantities of the component materials; the yield, that is, the volume of concrete per unit volume of cement; the actual cement factor; and the air content of the concrete.

NOTE.—This method of calculating air content is of value, particularly, for concrete made with air-entraining cement.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance or scale sensitive to 0.1 lb.

(*b*) *Tamping Rod.*—A straight metal rod, $\frac{5}{8}$ in. in diameter and approximately 24 in. in length with one end tapered for a distance of 1 in. to a blunt, bullet-shaped end.

(*c*) *Measure.*—A cylindrical metal measure, preferably provided with handles. The measure shall be watertight, preferably machined to accurate dimensions on the inside. It shall be reinforced around the top with a No. 10 to No. 12 U. S. gage steel band $1\frac{1}{2}$ in. in width. Depending upon the maximum nominal size of the coarse aggregate in the concrete, the measures required shall

TABLE I.—DIMENSIONAL REQUIREMENTS FOR CYLINDRICAL MEASURES.

Capacity, cu. ft.	Inside Diameter, in.	Inside Height, in.	Thickness of Metal, U. S. Gage	Maximum Nominal Size of Coarse Aggregate
½.....	10.00	11.00	No. 10 to No. 12	Up to 2 in., incl.
1.....	14.00	11.23	No. 10 to No. 12	Over 2 in.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, this method was published as tentative from 1938 to 1939.

have capacities of ½ or 1 cu. ft. and shall conform to the requirements prescribed in Table I.

Calibration of Measure

3. The measure shall be calibrated by accurately determining the weight of water at 62 F. (16.7 C.) required to fill it (Note). The factor for any measure shall be obtained by dividing the unit weight of water at 62 F. (16.7 C.), namely, 62.4 lb. per cu. ft., by the weight (in pounds) of water at 62 F. (16.7 C.) required to fill the measure.

NOTE.—Accurate filling of the measure may be secured by the use of a glass cover plate.

Sample

4. The sample of freshly-mixed concrete shall be obtained in accordance with the Standard Method of Sampling Fresh Concrete (A.S.T.M. Designation: C 172).[3]

Procedure

5. (*a*) *Sequence of Operations.*—The measure shall be filled to one third of its capacity and the mass of concrete rodded with the number of strokes prescribed in Paragraph (*b*), evenly distributed over the cross-section. The measure shall then be tapped, and filled to two thirds of its capacity, the mass of concrete again rodded, the measure tapped as before, and finally filled to overflowing, rodded and tapped as before.

(*b*) *Rodding.*—In rodding the first layer, the rod shall not strike forcibly the bottom of the measure. In rodding the second and final layers, only enough force shall be used to cause the rod to penetrate the surface of the previous layer. When the ½-cu. ft. measure is used, each layer shall be rodded with 25 strokes, and when the 1-cu. ft. measure is used each layer shall be rodded with 50 strokes.

(*c*) *Tapping.*—The exterior surface of the measure shall be tapped smartly 10 to 15 times or until no large bubbles of air appear on the surface of the rodded layer.

(*d*) *Strike-off, Cleaning, and Weighing.*—After consolidation of the concrete, the top surface shall be struck off and finished smoothly with a flat cover plate using great care to leave the measure just level full. All excess concrete shall then be cleaned from the exterior and the filled measure weighed to the nearest 0.1 lb.

Calculations

6. (*a*) *Weight per Cubic Foot.*—The net weight of the concrete shall be calculated by subtracting the weight of the measure from the gross weight. The weight per cubic foot shall be calculated by multiplying the net weight by the factor for the measure used, determined as described in Section 3.

(*b*) *Volume of Concrete.*—The volume of concrete produced per batch shall be calculated as follows:

$$S = \frac{(N \times 94) + W_f + W_c + W_w}{W}$$

where:

S = volume of concrete produced per batch, in cubic feet,
N = number of bags of cement in the batch,
94 = net weight of a bag of cement, in pounds,
W_f = total weight of fine aggregate in batch in condition used, in pounds,
W_c = total weight of coarse aggregate in batch in condition used, in pounds,
W_w = total weight of mixing water added to batch, in pounds, and
W = weight of concrete, in pounds per cubic foot.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*c*) *Yield.*—The yield shall be calculated as follows:

$$Y = \frac{S}{N}$$

where:

Y = yield of concrete produced per 94 pound bag of cement, in cubic feet,
S = volume of concrete produced per batch, in cubic feet, and
N = number of bags of cement in the batch.

(*d*) *Cement Factor.*—The "actual" cement factor shall be calculated as follows:

$$N_1 = \frac{27}{Y} \quad \text{or} \quad N_1 = \frac{27N}{S}$$

N_1 = number of bags of cement per cubic yard of concrete produced (actual cement factor)
Y = yield of concrete produced per 94 pound bag of cement, in cubic feet,
N = number of bags of cement in the batch, and
S = volume of concrete produced per batch, in cubic feet.

(*e*) *Air Content.*—The air content shall be calculated as follows:

$$A = \frac{T - W}{T} \times 100$$

or by the formula

$$A = \frac{S - V}{S} \times 100$$

where:

A = air content (percentage of voids) in the concrete,
T = theoretical weight of the concrete, in pounds per cubic foot, computed on an air-free basis (Note),
W = weight of concrete, in pounds per cubic foot,
S = volume of concrete produced per batch, in cubic feet, and
V = total absolute volume of the component ingredients in the batch, in cubic feet.

NOTE.—The theoretical weight per cubic foot is, customarily, a laboratory determination, the value for which is assumed to remain constant for all batches made, using identical component ingredients and proportions. It is calculated from the formula:

$$T = \frac{W_1}{V}$$

where:

T = theoretical weight of the concrete, in pounds per cubic foot, computed on an air-free basis,
W_1 = total weight of the component ingredients in the batch, in pounds, and
V = total absolute volume of the component ingredients in the batch, in cubic feet.

The absolute volume of each ingredient is equal to the quotient of the weight of that ingredient divided by the product of its specific gravity times 62.4. For the aggregate components, the bulk specific gravity and weight should be based on the saturated, surface-dry condition. For the cement, a value of 3.15 may be used unless the actual specific gravity is determined by the Standard Method of Test for Specific Gravity of Hydraulic Cement (A.S.T.M. Designation: C 188).[3]

Standard Definitions of

TERMS RELATING TO CONCRETE AND CONCRETE AGGREGATES[1]

A.S.T.M. Designation: C 125 - 44

ADOPTED, 1939; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 125; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Admixture.—In the case of concrete, a material other than cement, water and aggregate, mixed or to be mixed into concrete, or to any of the ingredients thereof.

Blast-Furnace Slag.—The nonmetallic product consisting essentially of silicates and alumino-silicates of lime, and of other bases, which is developed simultaneously with iron in a blast furnace.

Crushed Gravel.—The product resulting from the artificial crushing of gravel with substantially all fragments having at least one face resulting from fracture.

Crushed Stone.—The product resulting from the artificial crushing of rocks, boulders or large cobblestones, substantially all faces of which have resulted from the crushing operation.

Elongated Piece.—In the case of concrete aggregate, one in which the ratio of the length to width of its circumscribing rectangular prism is greater than a specified value.

Fineness Modulus.—In the case of aggregate for concrete, an empirical factor obtained by adding the total percentages of a sample of the aggregate retained on each of a specified series of sieves, and dividing the sum by 100.

NOTE.—The sieve sizes used are No. 100 (149-micron), No. 50 (297-micron), No. 30 (590-micron), No. 16 (1190-micron), No. 8 (2380-micron), and No. 4 (4760-micron) and ¾ in., 3 in., 1½ in., and larger, increasing in the ratio of 2 to 1.

Flat Piece.—In the case of concrete aggregate, one in which the ratio of the width to thickness of its circumscribing rectangular prism is greater than a specified value.

Gravel.—The coarse granular material, larger than sand, resulting from the natural erosion of rock.

Water-Cement Ratio.—The ratio of the amount of water, exclusive only of that absorbed by the aggregates, to the amount of cement in a concrete mixture. This ratio is variously stated as follows: (1) by bulk volume of cement (assuming cement to weigh 94 lb. per cu. ft.); (2) by absolute volume of cement; (3) by weight; and (4) in terms of gallons of water per 94 lb. sack of cement.

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, these definitions were published as tentative from 1936 to 1939.

Standard Specifications for

SODIUM SILICATE FOR CURING CONCRETE[1]

A.S.T.M. Designation: C 111 – 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation C 111; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover sodium silicate suitable for application to the surface of concrete for the purpose of preventing moisture loss during curing.

Properties and Tests

2. (*a*) The sodium silicate shall have a density of not less than 42.25° Baumé at 60 F. (15.5 C.).

(*b*) The ratio of sodium oxide, Na_2O, to silica, SiO_2, shall be 1 Na_2O to not less than 3.2 SiO_2.

Packing and Marking

3. The sodium silicate shall be delivered on the job in containers of suitable size and of a type which will not cause any deterioration of the product prior to its application to the concrete. The name of the manufacturer, the actual net weight, and the manufacturer's grade designation shall be plainly marked on each container.

Inspection and Sampling

4. Sodium silicate may be sampled for purpose of tests either at the plant prior to delivery or on the site of the work, at the option of the purchaser. At least one sample from each 500 gal. shall be taken to determine compliance with these specifications.

Rejection

5. The sodium silicate shall be rejected if it fails to meet any of the requirements of these specifications.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee C-9 on Concrete and Concrete Aggregates.

[2] Prior to adoption as standard, these specifications were published as tentative from 1934 to 1936. Editorially revised and rearranged in 1939.

Standard Specifications for

CRUSHED STONE AND CRUSHED SLAG FOR BITUMINOUS MACADAM BASE AND SURFACE COURSES OF PAVEMENTS[1]

A.S.T.M. Designation: D 693 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 693; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover the quality and grading of crushed stone and crushed slag suitable for use in the construction of bituminous macadam base and surface courses of pavements.

Basis of Purchase

2. In adapting these specifications to any particular locality or project, the type or types of aggregate (crushed stone or crushed slag) to be supplied shall be specified.

General Characteristics

3. (*a*) *Crushed Stone.*—The crushed stone shall consist of clean, tough, durable fragments free of an excess of thin or elongated pieces, and reasonably free of soft or disintegrated pieces, stone coated with dirt, or other objectionable matter.

(*b*) *Crushed Slag.*—The crushed slag shall be air-cooled blast-furnace slag and shall consist of fragments reasonably uniform in density and quality and reasonably free of thin or elongated pieces, dirt, or other objectionable matter.

Physical Properties

4. (*a*) *Wear.*—The aggregates shall conform to the following requirements for resistance to wear:

	Aggregate for Use in Base Courses	Aggregate for Use in Surface Courses
Wear, Los Angeles abrasion machine, max., per cent	50	40

(*b*) *Unit Weight of Slag.*—Crushed slag shall conform to the following requirements for unit weight, compacted:

	Crushed Slag for Use in Base Courses	Crushed Slag for Use in Surface Courses
Weight per cubic foot, compacted, min., lb.	65	70

NOTE.—The requirements for physical properties of aggregates incorporated in these specifications are recommended as the minimum requirements for quality. It is not expected, however, that these limits for quality will be applicable to all localities and conditions.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1942 to 1944, being revised in 1944.

These specifications are in effect a revision and consolidation of, and replace the former Tentative Specifications for Crushed Stone for Bituminous Macadam Base and Surface Courses (D 192 - 41 T) and for Crushed Slag for Bituminous Macadam Base and Surface Courses (D 487 - 42 T), which specifications were accordingly discontinued in 1942.

TABLE I.—GRADING REQUIREMENTS.

Size Number	Nominal Size (Sieves With Square Openings)	Amounts Finer than Each Laboratory Sieve (Square Openings), per cent by weight												
		4 in.	3½ in.	3 in.	2½ in.	2 in.	1½ in.	1 in.	¾ in.	½ in.	⅜ in.	No. 4 (4760-micron)	No. 8 (2380-micron)	No. 16 (1190-micron)
1	3½ to 1½ in.	100	90 to 100	....	25 to 60	....	0 to 15	....	0 to 5	....	....	....	....	....
2	2½ to 1½ in.	....	....	100	90 to 100	35 to 70	0 to 15	....	0 to 5	....	....	....	....	....
3	2 to 1 in.	....	....	....	100	90 to 100	35 to 70	0 to 15	....	0 to 5	....	....	....	....
5	1 to ¾ in.	....	....	....	....	....	100	90 to 100	40 to 75	15 to 35	0 to 15	0 to 5	....	....
6	¾ to ⅜ in.	....	....	....	....	....	....	100	90 to 100	20 to 55	0 to 15	0 to 5	....	....
67	¾ in. to No. 4	....	....	....	....	....	....	100	90 to 100	....	20 to 55	0 to 10	0 to 5	....
7	½ in. to No. 4	....	....	....	....	....	....	....	100	90 to 100	40 to 70	0 to 15	0 to 5	....
78	½ in. to No. 8	....	....	....	....	....	....	....	100	90 to 100	40 to 75	5 to 25	0 to 5	....
8	⅜ in. to No. 8	....	....	....	....	....	....	....	....	100	85 to 100	10 to 30	0 to 10	....
9	No. 4 to No. 16	....	....	....	....	....	....	....	....	....	100	85 to 100	10 to 40	0 to 10

Sizes

5. The sizes of aggregates for the various uses shall conform to the following requirements (Note):

	Size Number
Penetration course	1, 2, 3
Choke	5, 6, 67, 7, 78
Seal coat	7, 78, 8, 9

NOTE.—Sizes have been selected from the Tentative Specifications for Standard Sizes of Coarse Aggregate for Highway Construction (A.S.T.M. Designation: D 448).[2] An appropriate size should be selected for each use, depending on thickness of the base or surface course, quality of the aggregate, and on other local construction and service conditions.

For the harder aggregates, any of the sizes specified for penetration course aggregate may be appropriate, depending upon characteristics of the construction. For softer aggregates which tend to break down under the roller, the larger sizes should be used. The line of demarcation between harder and softer aggregates may be fixed conveniently by selection of limiting percentages of wear, Los Angeles machine, depending on characteristics of aggregates available in each locality.

The size of choke aggregate best suited for the work depends upon the size of surface voides in the penetration course and on fluidity of the bituminous binder. The more fluid binders require a densely graded choke aggregate (sizes 67 or 78), while the open gradations of aggregate are more suitable for the more viscous hot-application binders. The following combinations of size numbers are suggested:

Size of Penetration Course Aggregate	Size of Choke Aggregate	
	Viscous Binders	Fluid Binders
1	5	67
2	5 or 6	67 or 78
3	6 or 7	78

The size of seal-coat aggregate depends upon the type of surface desired.

Sieve Analysis

6. The several sizes of aggregates, when tested by means of laboratory sieves having square openings, shall conform to the requirements shown in Table I.

Methods of Sampling and Testing

7. The aggregates shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75).[3]

(*b*) *Wear.*—Standard Method of Test for Abrasion of Coarse Aggregate by Use of the Los Angeles Machine (A.S.T.M. Designation: C 131).[3]

(*c*) *Weight per Cubic Foot.*—Standard Method of Test for Unit Weight of Aggregate (A.S.T.M. Designation: C 29).[3]

(*d*) *Sieve Analysis.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[3]

[2] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

CRUSHED STONE, CRUSHED SLAG, AND GRAVEL FOR WATER-BOUND MACADAM BASE AND SURFACE COURSES OF PAVEMENTS[1]

A.S.T.M. Designation: D 694 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 694; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover the quality and grading of crushed stone, crushed slag, and gravel suitable for use in the construction of water-bound macadam base and surface courses of pavements.

Basis of Purchase

2. In adapting these specifications to any particular locality or project, the type or types of aggregate (crushed stone, crushed slag, or gravel) to be supplied shall be specified.

General Characteristics

3. (*a*) *Crushed Stone.*—The crushed stone shall consist of clean, tough, durable fragments free of an excess of thin or elongated pieces, and reasonably free of soft or disintegrated pieces, dirt, or other objectionable matter.

(*b*) *Crushed Slag.*—The crushed slag shall be air-cooled blast-furnace slag and shall consist of fragments reasonably uniform in density and quality and reasonably free of thin or elongated pieces, dirt, or other objectionable matter.

(*c*) *Gravel.*—The gravel shall consist of clean, tough, durable pieces free of an excess of thin or elongated pieces, and reasonably free of soft or disintegrated pieces, dirt, or other objectionable matter. The gravel shall be crushed and uncrushed, as specified in Section 5(*b*). Crushed gravel shall consist of fragments having two or more fractured surfaces.

(*d*) *Screenings.*—The screenings shall have a suitable binding quality.

Physical Properties

4. (*a*) *Wear.*—The aggregates shall conform to the following requirements for resistance to wear:

	Aggregate for Use in Base Courses	Aggregate for Use in Surface Courses
Wear, Los Angeles abrasion machine, max., per cent.....	60	40

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1942 to 1944.

These specifications are in effect a revision and consolidation of, and replace the former Tentative Specifications for Crushed Slag for Water-Bound Base and Surface Courses (D 488 - 38 T) and for Crushed Stone for Water-Bound Base and Surface Courses (D 489 - 40 T), which specifications were accordingly discontinued in 1942.

(*b*) *Unit Weight of Slag.*—Crushed slag shall conform to the following requirements for unit weight, compacted:

	Crushed Slag for Use in Base Courses	Crushed Slag for Use in Surface Courses
Weight per cubic foot, compacted, min., lb...	65	70

NOTE.—The requirements for physical properties of aggregates incorporated in these specifications are recommended as the minimum requirements for quality. It is not expected, however, that these limits for quality will be applicable to all localities and conditions.

(*b*) *Crushed Pieces in Gravel.*—Gravel shall contain not less than 75 per cent by weight of crushed pieces.

Sieve Analysis

6. The several sizes of aggregates, when tested by means of laboratory sieves having square openings, shall conform to the requirements shown in Table I.

Methods of Sampling and Testing

7. The aggregates shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75).[3]

(*b*) *Wear.*—Standard Method of Test for Abrasion of Coarse Aggregate by Use of the Los Angeles Machine (A.S.T.M. Designation: C 131).[3]

(*c*) *Weight per Cubic Foot.*—Standard Method of Test for Unit Weight of Aggregate (A.S.T.M. Designation: C 29).[3]

(*d*) *Sieve Analysis.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[3]

TABLE I.—GRADING REQUIREMENTS.

Size Number	Nominal Size (Sieves with Square Openings)	Amounts Finer than Each Laboratory Sieve (Square Openings), per cent by weight											
		4 in.	3½ in.	3 in.	2½ in.	2 in.	1½ in.	1 in.	¾ in.	½ in.	⅜ in.	No. 4 (4760-micron)	No. 100 (149-micron)
1	3½ to 1½ in.....	100	90 to 100	...	25 to 60	.....	0 to 15	...	0 to 5	...	...	...	...
2	2½ to 1½ in.....	...	...	100	90 to 100	35 to 70	0 to 15	...	0 to 5	...	...	...	...
3	2 to 1 in.....	...	...	...	100	90 to 100	35 to 70	0 to 15	...	0 to 5	...	...	...
10	No. 4 to 0.....	...	...	...	...	...	...	...	...	...	100	85 to 100	10 to 30

Sizes

5. (*a*) The sizes of aggregates for the various uses shall conform to the following requirements (Note):

	Size Number
Coarse aggregate.....	1, 2, 3
Screenings.....	10

NOTE.—An appropriate size should be selected for each use, depending on local construction and service conditions. Sizes have been selected from the Tentative Specifications for Standard Sizes of Coarse Aggregate for Highway Construction (A.S.T.M. Designation: D 448) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

GRANITE BLOCK FOR PAVEMENTS[1]

A.S.T.M. Designation: D 59 – 39

ADOPTED, 1922; REVISED, 1926, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 59; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover granite block for pavements.

Material

2. The blocks shall be of granite of medium-size grain, showing an even distribution of constituent minerals. They shall be of uniform quality and texture throughout, and free from seams or disintegrated materials.

Physical Properties

3. The average of three tests on sample blocks shall conform to the following requirements as to physical properties:

FOR HEAVY TRAFFIC	
Percentage of wear, not more than	3.6
(or French coefficient of wear, not less than	11)
Toughness, not less than	9
FOR MODERATELY HEAVY TRAFFIC	
Percentage of wear, not more than	5.0
(or French coefficient of wear, not less than	8)
Toughness, not less than	7

Methods of Testing

4. The properties enumerated in Section 3 shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Percentage of Wear and French Coefficient of Wear.*—Standard Method of Test for Abrasion of Rock by Use of the Deval Machine (A.S.T.M. Designation: D 2),[3] except that the sample shall be prepared by use of a press and the fragments shall be as uniform and as nearly cubical as practicable.

(*b*) *Toughness.*—Standard Method of Test for Toughness of Rock (A.S.T.M. Designation: D 3).[3]

Dimensions

5. The blocks shall conform to the following requirements as to dimensions:

Length on top, in.	8 to 12
Width on top, in.	$3\frac{1}{2}$ to $4\frac{1}{2}$ or $4\frac{1}{2}$ to $5\frac{1}{2}$
Depth, in.	$4\frac{3}{4}$ to $5\frac{1}{4}$

Dressing

6. (*a*) The blocks shall be so dressed that the faces will be approximately rectangular in shape, and the ends and sides sufficiently smooth to permit the blocks to be laid with joints not exceeding $\frac{1}{2}$ in. in width at the top, and for

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1919 to 1922, being revised in 1922.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

1 in. downward therefrom, and not exceeding 1 in. in width at any other part of the joint.

(*b*) The wearing surface of the blocks shall show no depressions more than $\frac{3}{8}$ in. in depth, and the edges and corners shall be unchipped and unbroken.

Inspection

7. At least six blocks shall be selected for physical tests by the engineer or his authorized representative, subsequent to delivery at the place of use, so as to fairly represent actual deliveries. No sample shall include blocks that would be rejected by a visual examination. The bedding plane shall be marked on at least two of the blocks selected.

Rejection

8. All deliveries shall be subjected to further inspection at the place of use, prior to and during laying. All blocks which fail to conform to the requirements of Sections 2, 5, and 6 shall be rejected.

Standard Specifications for

RECUT GRANITE BLOCK FOR PAVEMENTS[1]

A.S.T.M. Designation: D 131 – 39

ADOPTED, 1923; REVISED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 131; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover recut granite block for pavements.

Material

2. The blocks shall be of granite of medium-size grain, showing an even distribution of constituent minerals. They shall be of uniform quality and texture throughout, and free from seams or disintegrated materials.

Physical Properties

3. The average of three tests on sample blocks shall conform to the following requirements as to physical properties:

Percentage of wear	not more than 5
(or French coefficient of wear	not less than 8)
Toughness	not less than 7

Methods of Testing

4. The properties enumerated in Section 3 shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Percentage of Wear and French Coefficient of Wear.*—Standard Method of Test for Abrasion of Rock by Use of the Deval Machine (A.S.T.M. Designation: D 2),[3] except that the sample shall be prepared by use of a press and the fragments shall be as uniform and as nearly cubical as practicable.

(*b*) *Toughness.*—Standard Method of Test for Toughness of Rock (A.S.T.M. Designation: D 3).[3]

Dimensions

5. The blocks shall conform to the following requirements as to dimensions:

Length on top, in.	6 to 12
Width on top, in.	$3\frac{1}{2}$ to $4\frac{1}{2}$
Depth, in.	$4\frac{3}{4}$ to $5\frac{1}{4}$ [a]

[a] The depth may be varied by the engineer between 4 and 5 in., depth of blocks to suit the old material, provided that the blocks used on one contract shall vary not more than $\frac{1}{4}$ in. above or below the depth specified.

Dressing

6. (*a*) The blocks shall be so dressed that the faces will be approximately

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1923, being revised in 1923.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

rectangular in shape, and the ends and sides sufficiently smooth to permit the blocks to be laid with joints not exceeding $\frac{1}{2}$ in. in width at the top, and for 1 in. downward therefrom, and not exceeding 1 in. in width at any other part of the joint.

(*b*) The wearing surface of the blocks shall show no depressions more than $\frac{3}{8}$ in. in depth, and the edges and corners shall be unchipped and unbroken.

Inspection

7. At least eight blocks shall be selected for physical tests by the engineer or his authorized representative, subsequent to delivery at the place of use, so as to fairly represent actual deliveries. No sample shall include blocks that would be rejected by a visual examination. The bedding plane shall be marked on at least two of the blocks selected.

Rejection

8. All deliveries shall be subjected to further inspection at the place of use, prior to and during laying. All blocks which fail to conform to the requirements of Sections 2, 5, and 6 shall be rejected.

Standard Specifications for

GRANITE BLOCK FOR DURAX PAVEMENTS[1]

A.S.T.M. Designation: D 132 – 39

ADOPTED, 1923; REVISED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 132; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover granite block for Durax pavements.

Material

2. The blocks shall be of granite of medium-size grain, showing an even distribution of constituent minerals. They shall be of uniform quality and texture throughout, and free from seams or disintegrated materials.

Physical Properties

3. The average of three tests on sample blocks shall conform to the following requirements as to physical properties:

Percentage of wear	not more than 5
(or French coefficient of wear	not less than 8)
Toughness	not less than 7

Methods of Testing

4. The properties enumerated in Section 3 shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Percentage of Wear and French Coefficient of Wear.*—Standard Method of Test for Abrasion of Rock by Use of the Deval Machine (A.S.T.M. Designation: D 2),[3] except that the sample shall be prepared by use of a press and the fragments shall be as uniform and as nearly cubical as practicable.

(*b*) *Toughness.*—Standard Method of Test for Toughness of Rock (A.S.T.M. Designation: D 3).[3]

Dimensions

5. The blocks shall be not less than 3 in. nor more than 4 in. in length, width, or depth.

Dressing

6. (*a*) The blocks shall be so dressed that the faces will be approximately rectangular in shape, and the ends and sides sufficiently smooth to permit the blocks to be laid with joints not exceeding $\frac{1}{2}$ in. in width at the top, and for 1 in. downward therefrom, and not exceeding 1 in. in width at any other part of the joint.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1922 to 1923.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) The wearing surface of the blocks shall show no depressions more than $\frac{3}{8}$ in. in depth, and the edges and corners shall be unchipped and unbroken.

Inspection

7. At least 25 blocks shall be selected for physical tests by the engineer or his authorized representative, subsequent to delivery at the place of use, so as to fairly represent actual deliveries. No sample shall include blocks that would be rejected by a visual examination. The bedding plane shall be marked on at least two of the blocks selected.

Rejection

8. All deliveries shall be subjected to further inspection at the place of use, prior to and during laying. All blocks which fail to conform to the requirements of Sections 2, 5, and 6 shall be rejected.

APPROVED AS
AMERICAN TENTATIVE STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A31-1924

Standard Specifications for

MATERIALS FOR CEMENT GROUT FILLER FOR BRICK AND STONE BLOCK PAVEMENTS[1]

A.S.T.M. Designation: D 57 – 20

ADOPTED, 1920.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 57; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover the materials (sand, portland cement, and water) for use in cement grout filler for brick and stone block pavements.

SAND

General Characteristics

2. The sand shall consist of clean, hard, durable stone particles, preferably siliceous, free from lumps of clay and objectionable foreign matter.

Grading

3. (*a*) The sand shall be well graded from coarse to fine and when tested by means of laboratory sieves shall conform to the following requirements:

Sieve	Percentage Passing
No. 10 (2000-micron)	100
No. 20 (840-micron) not less than	80
No. 200 (74-micron) not more than	5

(*b*) The sieve analysis of the sand shall be made in accordance with Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[3]

Mortar Strength

4. (*a*) The sand shall be mixed with Portland cement conforming to the requirements for type I of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials,[3] in the proportion of 1 part of cement to 3 parts of sand, by weight, according to the standard method of making 1:3 mortar briquets. The resulting mortar at the age of 7 and 28 days shall have a tensile strength of at least 75 per cent of that developed in the same time by mortar of the same consistency, made of 1 part of the same cement and 3 parts of Ottawa sand.

(*b*) Preliminary acceptance samples shall be subjected to mortar strength tests at both 7 days and 28 days, and

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1919 to 1920. Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

acceptance based thereon. Samples tested during the progress of the work will be accepted on the basis of the 7-day test.

(*c*) The tests for mortar strength shall be made in accordance with the Standard Methods of Test for Tensile Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 190).[3]

NOTE.—The portland cement used in testing the proposed sand should preferably be that used or to be used in the work.

Inspection

5. The sand shall be subject to inspection after delivery at the place of use, prior to and during the laying of the pavement.

Sampling

6. The sand shall be sampled for testing at the source of supply, if required. Samples shall also be taken for testing from time to time, at the place of use prior to and during the laying of the pavement, whenever desired by the engineer.

PORTLAND CEMENT

Cement

7. Portland cement for use in cement grout filler shall conform to the requirements for type I of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

WATER

Water

8. The water used shall be clean and free from harmful amounts of oil, acid, alkali, organic or vegetable matter.

Standard Specifications for

MATERIALS FOR SAND-CEMENT BED FOR BRICK AND BLOCK PAVEMENTS[1]

A.S.T.M. Designation: D 58 – 37

ADOPTED, 1920; REVISED, 1924, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 58; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover the materials (sand and portland cement) for use in sand-cement bed for brick, stone block, wood block, asphalt block, and other block pavements.

SAND

General Characteristics

2. The sand shall consist of clean, hard, durable stone particles, preferably siliceous, free from lumps of clay and objectionable foreign matter.

Grading

3. (*a*) The sand shall be well graded from coarse to fine and when tested by means of laboratory sieves shall conform to the following requirements:

Sieve	Percentage Passing
No. 4 (4760-micron)	100
No. 8 (2380-micron) not less than	90

(*b*) The sieve analysis of the sand shall be made in accordance with the Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[3]

Mortar Strength

4. (*a*) The sand shall be passed through a No. 8 (2380-micron) sieve and that portion retained by the No. 8 sieve shall be discarded. The portion passing a No. 8 sieve shall be mixed with portland cement conforming to the requirements for type I of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials,[3] in the proportion of 1 part cement to 3 parts of sand, by weight, according to the standard method of making 1:3 mortar briquets. The resulting mortar at the age of 7 and 28 days shall have a tensile strength of at least 75 per cent of that developed in the same time by mortar of the same consistency, made of 1 part of the same cement and 3 parts of Ottawa sand.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1919 to 1920. Editorially revised and rearranged in 1939.

These specifications comprise a revision of the Standard Specifications for Materials for Cement Mortar Bed for Brick, Stone Block, Wood Block, Asphalt Block and Other Block Pavements (A.S.T.M. Designation: D 58 – 24), which specifications they supersede.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) Preliminary acceptance samples shall be subjected to mortar strength tests at both 7 days and 28 days, and acceptance based thereon. Samples tested during the progress of the work will be accepted on the basis of the 7-day test.

(*c*) The tests for mortar strength shall be made in accordance with the Standard Methods of Test for Tensile Strength of Hydraulic-Cement Mortars (A.S.T.M. Designation: C 190).[3]

NOTE.—The portland cement used in testing the proposed sand should preferably be that used or to be used in the work.

Inspection

5. The sand shall be subject to inspection after delivery at the place of use, prior to and during the laying of the pavement.

Sampling

6. The sand shall be sampled for testing at the source of supply, if required. Samples shall also be taken for testing from time to time, at the place of use prior to and during the laying of the pavement, whenever desired by the engineer.

PORTLAND CEMENT

Cement

7. Portland cement for use in the cement mortar bed shall conform to the requirements for type I of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials.[3]

Standard Specifications for

MINERAL FILLER FOR SHEET ASPHALT AND BITUMINOUS CONCRETE PAVEMENTS[1]

A.S.T.M. Designation: D 242 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 242; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover mineral filler for sheet asphalt and bituminous concrete pavements.

Composition

2. The mineral filler shall consist of limestone dust, portland cement, or other mineral matter from sources agreed upon by the purchaser and the seller.

Physical Properties

3. The material shall be thoroughly dry and free from lumps consisting of aggregations of fine particles. When tested by means of laboratory sieves the mineral filler shall conform to the following requirements:

Sieve	Percentage Passing
No. 200 (74-micron)	not less than 65
No. 80 (177-micron)	not less than 95
No. 30 (590-micron)	100

Method of Testing

4. The sieve analysis of the mineral filler shall be made in accordance with the Standard Method of Test for Sieve Analysis of Mineral Filler (A.S.T.M. Designation: D 546) of the American Society for Testing Materials.[3]

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1926 to 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

SAND FOR SHEET ASPHALT AND BITUMINOUS CONCRETE PAVEMENTS[1]

A.S.T.M. Designation: D 162 - 29

ADOPTED, 1929.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 162; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover sand for use in the construction of the surface course of sheet asphalt pavements and those types of bituminous concrete pavements in which sand predominates.

Physical Properties

2. (*a*) The grains of the sand shall be clean, tough, rough-surfaced, and angular. The sand after drying shall be free from lumps or balls of clay or of clay and sand. Before being incorporated into the paving mixture, it shall conform to the following requirements as to grading:

Passing Sieve		Retained on Sieve	Per cent	
No. 200	(74-micron)		0 to 5	
No. 100	(149-micron)	No. 200	6 to 25	15 to 40
No. 80	(177-micron)	No. 100	6 to 25	
No. 50	(297-micron)	No. 80	5 to 40	30 to 60
No. 40	(420-micron)	No. 50	5 to 30	
No. 30	(590-micron)	No. 40	8 to 25	
No. 20	(840-micron)	No. 30	5 to 15	18 to 50
No. 10	(2000-micron)	No. 20	5 to 15	
No. 10	(2000-micron)		95 to 100	
No. 4	(4760-micron)		100	

(*b*) *General Characteristics.*—The general characteristics shall be determined by examination under a microscope or a magnifying glass.

Sampling

3. The sand shall be sampled in accordance with the Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75) of the American Society for Testing Materials.[3]

Methods of Testing

4. The sieve analysis shall be made on samples of dried sand, weighing not less than 100 g., following the procedure described in Section 5 of the Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[3] Determination of percentage of particles passing a No. 200 (74-micron) sieve shall be made by dry sieving.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1923 to 1929. Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

PREFORMED EXPANSION JOINT FILLERS FOR CONCRETE[1]

NONEXTRUDING AND RESILIENT TYPES

A.S.T.M. Designation: D 544 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 544; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover preformed expansion joint fillers of the following four types for use in concrete construction. The type or types desired shall be specified by the purchaser.

Type I, cork,
Type II, self-expanding cork,
Type III, sponge rubber, and
Type IV, cork rubber.

Manufacture

2. (*a*) *Cork and Self-Expanding Cork.*—These types shall consist of preformed strips which have been formed from clean granulated cork particles securely bound together by a synthetic resin of an insoluble nature. The granulated cork shall be relatively free from hard particles or dust and shall not have been exposed in the process of manufacture to a temperature exceeding 300 F. (149 C.).

(*b*) *Sponge Rubber.*—This type shall consist of preformed strips composed essentially of a durable, elastic rubber compound which may be reinforced on each side with a layer of asphalt treated felt which has been bonded to the rubber compound filler under heat and pressure.

(*c*) *Cork Rubber.*—This type shall consist of preformed strips which have been formed from clean granulated cork particles securely bound together by a durable elastic rubber compound. The granulated cork shall be relatively free from hard particles or dust and shall not have been exposed in the process of manufacture to a temperature exceeding 300 F. (149 C.).

Character of Strips

3. Preformed strips of expansion joint fillers shall be of such character as not to be deformed or broken by twisting, bending, or other ordinary handling when exposed to atmospheric conditions. Pieces of the joint filler which have been damaged shall be rejected.

Properties

4. (*a*) *Recovery.*—The test specimen shall be given three applications of a load sufficient to compress the material

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1939 to 1941.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

to 50 per cent of its thickness before test. The load shall be immediately released after each application. At the end of 1 hr. after the third application, the joint shall have recovered to at least 90 per cent of its thickness before test.

(*b*) *Compression.*—The load required to compress the test specimen to 50 per cent of its thickness before test shall not be less than 100 nor more than 750 psi.

(*c*) *Extrusion.*—The test specimen shall be compressed to 50 per cent of its thickness before test with three of the edges restrained. The amount of extrusion of the free edge shall not exceed 0.25 in.

(*d*) *Expansion.*—In the case of self-expanding cork (type II) expansion joint filler only, the test specimen after being immersed in boiling water for 1 hr. shall have a final thickness not less than 140 per cent of the thickness before test. Discoloration of the water shall not be considered an indication of failure.

(*e*) *Boiling in Hydrochloric Acid.*—In the case of cork and self-expanding cork (types I and II) expansion joint fillers only, the test specimen when boiled for 1 hr. in hydrochloric acid (sp. gr. 1.19) shall show no evidence of disintegration. Discoloration, or a small amount of swelling shall not be considered as failure.

(*f*) *Weathering Test.*—A weathering test may be conducted in accordance with the procedure specified in Section 8. Test specimens shall show no evidence of disintegration when subjected to the specified weathering test. Test specimens which have been subjected to the weathering test may be required to meet the requirements for recovery, compression, and extrusion specified in Section 4 (*a*), (*b*), and (*c*).

Dimensions and Permissible Variations

5. The preformed strips shall conform to the dimensions specified or shown on the plans. Strips of the joint filler which do not conform to the specified dimensions, within the permissible variations of plus $\frac{1}{16}$ in. in thickness, plus or minus $\frac{1}{8}$ in. in depth, and plus or minus $\frac{1}{4}$ in. in length shall be rejected.

Packing

6. Self-expanding cork shall be wrapped in waterproof paper, sealed in a manner that will prevent the entrance of moisture, and packed at the plant in sizes convenient for handling on the job.

Sampling

7. (*a*) *Size of Samples.*—Each sample shall consist of sufficient material to provide at least 5 test specimens measuring $4\frac{1}{2}$ by $4\frac{1}{2}$ in.

(*b*) *Number of Samples.*—One representative sample shall be selected from each shipment of 1000 sq. ft. or fraction thereof of each thickness ordered.

(*c*) Samples shall be packed for transportation in such a manner that there will be no danger of distortion or breakage. Samples of self-expanding cork, in addition to the above, shall be kept dry as received and wrapped for transportation in a manner that will prevent the entrance of moisture.

Methods of Testing

8. The properties enumerated in these specifications shall be determined in accordance with the Standard Methods of Testing Preformed Expansion Joint Fillers for Concrete (A.S.T.M. Designation: D 545) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

CALCIUM CHLORIDE[1]

A.S.T.M. Designation: D 98 – 34

ADOPTED, 1934.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 98; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover calcium chloride to be used for road purposes, acceleration of concrete, and curing of concrete.

Chemical Composition

2. The calcium chloride shall conform to the following requirements as to chemical composition:

Calcium chloride, $CaCl_2$ (anhydrous), min., per cent	77
Magnesium chloride, $MgCl_2$, max., per cent	0.5
Total alkali chlorides, max., per cent	2.0
Other impurities, max., per cent.	1.0

Grading

3. The calcium chloride shall be in the form of flakes and when tested by means of laboratory sieves[3] shall conform to the following requirements:

Passing a $\frac{3}{8}$-in. sieve	100 per cent
Retained on a $\frac{1}{4}$-in. sieve, max.	20 per cent
Passing an 840-micron (No. 20) sieve, max.	10 per cent

Packing and Marking

4. The calcium chloride shall be delivered in moistureproof bags or sacks containing approximately 100 lb. each, or in airtight steel drums weighing not more than 450 lb. each The name of the manufacturer, the lot number, the approximate net weight, and the percentage of calcium chloride guaranteed by the manufacturer shall be legibly marked on each container.

Inspection

5. Every facility shall be provided the purchaser should he elect to have his representative sample the material at the plant. If the purchaser decides to sample the material after delivery it is understood that a 3 per cent variation in content of $CaCl_2$ from the chemical composition prescribed in Section 2 shall be permissible.

Rejection

6. The calcium chloride shall be rejected if it fails to conform to any of the requirements of these specifications, and if it has become caked or sticky in the containers before opening.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1921 to 1934, being revised in 1922, 1930, 1933, and 1934. Editorially revised and rearranged in 1939.

[3] Detailed requirements for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for
SODIUM CHLORIDE[1]

A.S.T.M. Designation: D 632 – 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 632; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover sodium chloride to be used for road purposes.

Chemical Composition

2. The sodium chloride shall conform to the following requirement as to chemical composition:

Sodium chloride (NaCl), min., per cent	98.0

Grading

3. (*a*) The sodium chloride, when used in the form of rock salt, shall conform to the following requirements as determined by laboratory sieves:[3]

Retained on a No. 4 (4760-micron) sieve, max., per cent	12
Retained on a No. 8 (2380-micron) sieve, per cent	60 to 95
Passing a No. 30 (590-micron) sieve, max., per cent	7

(*b*) Evaporated salt may be used in lieu of rock salt when it conforms to the requirement as to chemical composition prescribed in Section 2. If the evaporated salt gives indications of caking, it shall be screened, and only the portion passing the No. 4 (4760-micron) sieve shall be used.

Packing and Marking

4. The sodium chloride shall be delivered in bags or sacks, drums, or bulk carload lots. The name of the manufacturer, the lot number, the approximate net weight, and the percentage of sodium chloride guaranteed by the manufacturer shall be legibly marked on each container, or in the case of carload shipments, noted on the shipping report.

Inspection

5. Every facility shall be provided the purchaser should he elect to have his representative sample the material at the place of manufacture. If the purchaser decides to sample the material after delivery, it is understood that a 0.5 per cent variation in content of sodium chloride from the chemical composition prescribed in Section 2 shall be permissible.

Rejection

6. The sodium chloride shall be rejected if it fails to conform to any of the requirements of these specifications.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard these specifications were published as tentative from 1941 to 1943.

[3] Detailed requirement for these sieves are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Method of Test for

ABRASION OF ROCK BY USE OF THE DEVAL MACHINE[1]

A.S.T.M. Designation: D 2 - 33

ADOPTED, 1908; REVISED, 1926, 1933.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 2; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the procedure for testing rock for resistance to abrasion in the Deval testing machine.

NOTE.—This well-known method of test is similar in almost all respects to the Deval abrasion test of the French School of Roads and Bridges. It has been used since 1878, and is entirely satisfactory for the purpose for which it was designed.

Apparatus

2. (*a*) *Deval Machine.*—The Deval abrasion testing machine shall consist of one or more hollow cast-iron cylinders closed at one end and furnished with a tightly fitting iron cover at the other. The inside dimensions of the cylinders shall be 20 cm. in diameter and 34 cm. in depth. These cylinders shall be mounted on a shaft at an angle of 30 deg. with the axis of rotation of the shaft.

(*b*) *Sieve.*—The No. 12 (1680-micron) square hole sieve shall conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

Test Sample

3. At least 30 lb. of coarsely broken stone shall be available for a test. The rock to be tested shall be broken into pieces as nearly uniform in size as possible, and as nearly 50 pieces as possible shall constitute a test sample. The total weight of rock used as the test sample shall be 5 kg. weighed to the nearest 10 g. All test pieces shall be washed and thoroughly dried before weighing.

Procedure

4. The test sample shall be placed in the Deval abrasion machine and the machine rotated for 10,000 revolutions at a rate of from 30 to 33 r.p.m. At the completion of the test, the material shall be removed from the machine and sieved on a No. 12 (1680-micron) sieve. The material passing the No. 12 sieve shall be considered in determining the amount of wear which shall be expressed, either as a percentage of the 5-kg. sample used in the test, or as the French coefficient of wear calculated as follows:

$$\text{Coefficient of wear} = 20 \times \frac{20}{W} = \frac{400}{W}$$

where: W = weight in grams of the detritus under 0.168 cm. (0.066 in.) in size per kilogram of rock used.

[1] Under the standardization procedure of the Society this method is under the jurisdiction of the A.S.T.M Committee D-4 on Road and Paving Materials.

[2] Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A5-1930

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 5-35

Standard Method of Test for

TOUGHNESS OF ROCK[1]

A.S.T.M. Designation: D 3 – 18

ADOPTED, 1908; REVISED, 1918.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 3; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the toughness of rock.

Toughness

2. Toughness, as applied to rock, is the resistance offered to fracture under impact, expressed as the final height of blow required of a standard hammer to cause fracture of a cylindrical test specimen of given dimensions.

Apparatus

3. Any form of impact machine which will comply with the following essentials may be used in making the test:

(*a*) A cast-iron anvil weighing not less than 50 kg., firmly fixed upon a solid foundation.

(*b*) A hammer weighing 2 kg., arranged so as to fall freely between suitable guides.

(*c*) A plunger made of hardened steel and weighing 1 kg., arranged to slide freely in a vertical direction in a sleeve, the lower end of the plunger being spherical in shape with a radius of 1 cm.

(*d*) Means for raising the hammer and for dropping it upon the plunger from any specified height from 1 to not less than 75 cm., and means for determining the height of fall within approximately 1 mm.

(*e*) Means for holding the cylindrical test specimen securely on the anvil without rigid lateral support, and under the plunger in such a way that the center of its upper surface shall, throughout the test, be tangent to the spherical end of the plunger at its lowest point.

Sampling

4. Quarry samples of rock from which test specimens are to be prepared shall measure at least 6 in. on a side and at least 4 in. in thickness, and when possible shall have the plane of structural weakness of the rock plainly marked thereon. Samples should be taken from freshly quarried material, and only from pieces which show no evidences of incipient fracture due to blasting or other causes.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Editorially revised and rearranged in 1939.

The samples should preferably be split from large pieces by the use of plugs and feathers and not by sledging. Commercial stone-block samples from which test specimens are to be prepared shall measure at least 3 in. on each edge.

Test Specimens

5. Specimens for test shall be cylinders 25 mm. in height and from 24 to 25 mm. in diameter, prepared as described in Section 6. Three specimens shall constitute a test set. The ends of the specimen shall be plane surfaces at right angles to the axis of the cylinder.

Preparation of Test Specimens

6. One set of specimens shall be drilled perpendicular and another parallel to the plane of structural weakness of the rock, if such plane is apparent. If a plane of structural weakness is not apparent, one set of specimens shall be drilled at random. Specimens shall be drilled in a manner that will not subject the material to undue stresses and which will insure the specified dimensions.[3] The ends of the cylinders may be sawed by means of a band or diamond saw,[4] or in any other way which will not induce incipient fracture, but shall not be chipped or broken off with a hammer. After sawing, the ends of the specimens shall be ground plane with water and carborundum or emery on a cast-iron lap until the cylinders are 25 mm. in height.

Procedure

7. The test shall consist of a 1-cm. fall of the hammer for the first blow, a 2-cm. fall for the second blow, and an increase of 1-cm. fall for each succeeding blow until failure of the test specimen occurs.

Report

8. The height of the blow in centimeters at failure shall be the toughness of the test specimen. The individual and the average toughness of three test specimens shall be reported when no plane of structural weakness is apparent. In cases where a plane of structural weakness is apparent, the individual and average toughness of the three specimens in each set shall be reported and identified. Any peculiar condition of a test specimen which might affect the result, such as the presence of seams, fissures, etc., shall be noted and recorded with the test result.

[3] The form of diamond drill described in *Bulletin No. 347*, U. S. Department of Agriculture, pp. 6–7, is recommended, and should prove satisfactory if the instructions are strictly followed.

[4] A satisfactory form of diamond saw is described in *Bulletin No. 347*, U. S. Department of Agriculture, pp. 7–9.

Standard Method of Test for
SIEVE ANALYSIS OF MINERAL FILLER[1]

A.S.T.M. Designation: D 546-41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 546; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the sieve analysis of mineral fillers used in road and paving materials.

Apparatus

2. (*a*) *Balance.*—The balance shall be sensitive to 0.05 g.

(*b*) *Sieves.*—The sieves shall conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[3] and shall include the No. 200 (74-micron) sieve and such other sieves as may be required by the specifications for the mineral filler.

NOTE.—In general specifications require the use of the No. 200 (74-micron), No. 80 (177-micron), and No. 30 (590-micron) sieves.

Sample

3. The sample for sieve analysis shall be obtained, by quartering or by use of a sampler, from a representative sample selected from the material to be tested. Approximately 50 g. of dry material is required for each test.

Drying of Sample

4. The sample shall be dried to substantially constant weight at a temperature not exceeding 110 C. (230 F.).

Procedure

5. (*a*) The 50.0 ± 5.0 g. sample of the dried mineral filler shall be weighed to the nearest 0.1 g. and placed on the No. 200 (74-micron) sieve which shall be thoroughly clean and dry. The sieve, with pan and cover attached, shall be held in one hand in a slightly inclined position so that the sample will be well distributed over the sieve, at the same time gently striking the side about 150 times per minute against the palm of the other hand on the up stroke. The sieve shall be turned every 25 strokes about one-sixth of a revolution in the same direction. The operation shall be continued until not more than 0.05 g. passes through the sieve in 1 min. of continuous sieving.

(*b*) The portion of the sample retained on the sieve shall then be weighed to the

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1939 to 1941.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

nearest 0.1 g., and placed on the sieve with the next larger opening for the series selected for the sieve analysis. Sieving shall be continued in a similar manner, using successively each of the selected series of sieves in the order of increasing size of opening, and recording the weight of that portion of the sample retained on each sieve. The weight of material and percentage of the sample passing each of the sieves shall be calculated.

(*c*) Washers, shot, or slugs shall not be used on the sieves.

Machine Sieving

6. Mechanical sieving devices may be used but the filler shall not be rejected if it meets the requirements when tested by the hand method described in Section 5. When mechanical sieving devices are used their thoroughness of sieving shall be tested by using the hand method.

Report

7. The report shall include the following:

(*a*) Results of the sieve analysis reported as the total percentage passing each sieve, expressed to the nearest 0.5 per cent, and

(*b*) The method of sieving used.

Reproducibility of Results

8. The percentages obtained by the same operator in duplicate tests on portions of the same sample should not differ by more than one passing any one sieve. The percentages obtained by different operators in different laboratories should not differ by more than two passing any one sieve.

Standard Methods of Testing

PREFORMED EXPANSION JOINT FILLERS FOR CONCRETE[1]

NONEXTRUDING AND RESILIENT TYPES

A.S.T.M. Designation: D 545 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 545; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover the following tests for preformed expansion joint fillers for concrete: expansion in boiling water, recovery, compression, extrusion, boiling in hydrochloric acid, and weathering. The recovery, compression, and extrusion tests shall be performed at a laboratory room temperature of 70 F. (21 C.) or above.

Preparation of Test Specimens

2. (*a*) In the case of cork, sponge rubber, and cork rubber (types I, III, and IV) expansion joint fillers only, five specimens for test shall be cut from each sample. Each test specimen shall be freshly and squarely cut using a metal plate 4 by 4 in. as a cutting template. The metal template shall be machined from $\frac{1}{4}$-in. plate to fit the extrusion mold described in Section 5 (*b*). The template shall fit the mold within minus 0.005 in. in length and minus 0.005 in. in width.

(*b*) In the case of self-expanding cork, (type II) expansion joint fillers only, subsequent to boiling in water as described in Section 3, the test specimens shall be permitted to air-dry for 24 hr., and shall then be cut to size and measured as described in Paragraph (*a*).

(*c*) The thickness of each test specimen shall be determined to the nearest 0.001 in.

Expansion in Boiling Water

3. In the case of self-expanding cork (type II) expansion joint filler only, five test specimens measuring $4\frac{1}{2}$ by $4\frac{1}{2} \pm 0.10$ in. shall be cut from each sample. The thickness of each test specimen shall be determined to the nearest 0.001 in. The specimens shall be immersed in boiling water for 1 hr., after which they shall be removed and allowed to cool to room temperature for 15 min. The final thickness of each specimen shall then be measured to the nearest 0.001 in.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1939 to 1941.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

Recovery and Compression

4. (*a*) *Test Specimens.*—One of the test specimens prepared as described in Section 2 (*a*) (or one of the expanded specimens prepared as described in Section 2 (*b*) in the case of self-expanding cork, type II) shall be used for these tests. In the case of cork, sponge rubber, and cork rubber (types I, III, and IV) expansion joint fillers, these tests shall be made on specimens of the material as received. However, if the cork filler (type I) fails to meet the requirements specified, check tests shall be made on specimens which have been immersed in water for 24 hr. and subsequently air dried for 24 hr. Acceptance shall be based on the results of these check tests.

(*b*) *Mounting.*—The test specimen shall be placed on a flat metal plate, and a $4\frac{1}{2}$ by $4\frac{1}{2}$ by $\frac{1}{2}$-in. metal plate ground to have plane parallel faces shall be centered on the top surface of the specimen. A simple U-shaped bridge shall be employed to support a dial or other suitable measuring device reading to 0.001 in. above the center of the specimen. A metal cylinder or other device for transferring the load from the moving head of the testing machine around the measuring apparatus to the plate covering the specimen shall be placed upon the plate. A spherical bearing block shall be mounted between the upper end of the cylinder and the moving head of the testing machine.

(*c*) *Measurement of Thickness.*—When the specimen has been mounted as described in Paragraph (*b*) and is subjected only to the pressure of the dead weight of the $4\frac{1}{2}$ by $4\frac{1}{2}$ by $\frac{1}{2}$-in. metal plate, its thickness shall be determined by means of the measuring device. When the load transferring apparatus and spherical bearing block are placed on the test specimen, some compression may result. This reduction in thickness shall be considered as part of the 50 per cent reduction in thickness to be applied (Paragraph (*d*)).

(*d*) *Recovery.*—For the determination of the percentage of recovery, the test specimen shall be given three applications of a load sufficient to compress it to 50 per cent of its thickness before test. The load shall be applied without shock and at such a rate that the specimen will be compressed approximately 0.05 in. per min. After the first and second applications the load shall be released immediately, and the specimen permitted to recover 30 min. before the load is again applied. After the third application the load shall be released immediately and the specimen shall be permitted to recover 1 hr., after which the thickness shall again be measured. The load-transferring apparatus and spherical bearing block shall be removed from the test specimen during recovery periods between compressions and following the third application of load. The percentage of recovery shall be calculated as follows:

$$\text{Recovery, per cent} = \frac{t'}{t} \times 100$$

where:

t = thickness of the specimen before test, and

t' = thickness 1 hr. after completion of the third application of load.

(*e*) *Compression.*—The total maximum load in pounds required for the first application as specified in Paragraph (*d*) shall be divided by 16 and recorded as the unit pressure in pounds per square inch.

Extrusion

5. (*a*) *Test Specimens.*—One of the test specimens prepared as described in Section 2 (*a*) (or one of the expanded

specimens prepared as described in Section 2 (*b*) in the case of self-expanding cork, type II) shall be used for this test. In the case of cork, sponge rubber, and cork rubber (types I, III, and IV) expansion joint fillers, these tests shall be made on specimens of the material as received. However, if the cork filler (type I) fails to meet the requirements of the specifications, check tests shall be made on specimens which have been immersed in water for 24 hr. and subsequently air dried for 24 hr. Acceptance shall be based on the results of these check tests.

(*b*) *Mounting.*—The test specimen shall be placed in a suitable steel mold so constructed as to confine the lateral movement of the specimen under compression to one side only. Interior dimensions of the mold shall be 4 by 4 in. with permissible variations in length and in width of plus or minus 0.015 in. Mold sides shall be of such height as to extend at least ½ in. above the test specimen. The specimen shall then be covered with a ½-in. metal plate ground to have plane parallel faces. The metal plate shall be machined to fit within the three restraining sides of the steel mold snugly but without binding. A simple U-shaped bridge shall be employed to support above the center of the specimen a dial or other suitable measuring device reading to 0.001 in. A metal cylinder or other device for transferring the load from the moving head of the testing machine around the measuring apparatus to the plate covering the specimen shall be placed upon the plate. A spherical bearing block shall be mounted between the upper end of the cylinder and the moving head of the testing machine.

(*c*) *Measurement of Thickness.*—When the specimen has been mounted as described in Paragraph (*b*) and is subjected only to the pressure of the dead weight of the 4 by 4 by ½-in. metal plate, its thickness shall be determined by means of the measuring device. When the load transferring apparatus and spherical bearing block are placed on the test specimen, some compression may result. This reduction in thickness shall be considered as part of the 50 per cent reduction in thickness to be applied (Paragraph (*d*)).

(*d*) *Extrusion.*—For the determination of the amount of extrusion, the specimen shall be given one application of a load sufficient to compress it to 50 per cent of its thickness before test. The load shall be applied without shock at such a rate that the specimen will be compressed approximately 0.05 in. per min. The amount of extrusion in inches shall be determined by measuring the maximum movement of the free edge of the test specimen during the 50 per cent compression of the specimen. The extrusion shall be measured by means of a dial or other suitable device reading to 0.001 in.

Boiling in Hydrochloric Acid

6. In the case of cork and self-expanding cork (types I and II) expansion joint fillers only, one of the test specimens prepared as described in Section 2 (*a*) (or one of the expanded specimens prepared as described in Section 2 (*b*) in the case of self-expanding cork, type II) shall be used for this test. The specimen shall be boiled for 1 hr. in hydrochloric acid (sp. gr. 1.19). The test specimen shall be examined for evidences of disintegration.

Accelerated Weathering Tests

7. (*a*) Two specimens, prepared as described in Section 2 (*a*) (or two of the of the expanded specimens prepared as described in Section 2 (*b*) in the case of self-expanding cork, type II) shall be exposed to a temperature of 165 F.

(74 C.) for a period of seven days. Upon completion of this accelerated aging test, the specimens shall be immersed in water at room temperature for 24 hr.

(*b*) The specimens shall then be placed on edge in a suitable container and water poured into the container to a depth of 2 in. (one-half the height of the specimens). It will be necessary to put a weight or simple frame across the exposed edges of the specimens during this test in order that the positions of the specimens in the water will be maintained. The pan containing the specimens partially immersed in water shall be placed in a freezing chamber for a period long enough to freeze the water into solid ice. The temperature of the freezing chamber shall be maintained between + 14 and − 4 F. (− 10 and − 20 C.). Upon completion of the freezing cycle, the pan containing the specimens shall be removed from the freezing chamber and partially immersed in water at a temperature maintained between 65 and 100 F. (18 and 38 C.). The first cycle is completed when the ice surrounding the specimens has melted entirely. This cycle shall be repeated ten times.

(*c*) The length of time required for freezing and thawing will be governed by the temperature of the freezing chamber and the volume of water around the specimens.

(*d*) After ten freezing-and-thawing cycles have been completed, the specimens shall be removed from the water and allowed to stand in air at room temperature for 48 hr. The test specimens shall be examined for evidences of disintegration.

Standard Methods of

CHEMICAL ANALYSIS OF CALCIUM CHLORIDE[1]

A.S.T.M. Designation: D 345 – 34

ADOPTED, 1934.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 345; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover procedures for the chemical analysis of calcium chloride.

Total Calcium

2. (*a*) Weigh accurately a sample of approximately 5 g. (Note 1) and dissolve in water. Add sufficient HCl to clear, and then make up to a volume of 500 ml. Pipette a 25.00 ml. aliquot and add enough diluted NH_4OH to make slightly alkaline. Methyl orange or red may be used as indicator. Add 20 ml. of cold saturated NH_4Cl solution and dilute to from 100 to 125 ml. Heat to boiling and, while stirring to precipitate the calcium, add 20 ml. of cold saturated $(NH_4)_2C_2O_4$. Let stand 1 min., and if the precipitate does not show a tendency to settle well, bring back to boiling and continue the stirring. Let settle 20 min. and filter through No. 42, 11-cm. Whatman filters or paper of an equivalent grade. Wash free from oxalate and chloride with hot water. Wash the precipitate back into the original beaker and dilute to about 100 ml. Dissolve the precipitate with 10 to 15 ml. of diluted H_2SO_4 (1:4), heat to about 80 C., and titrate to a pink color with 0.1 *N* $KMnO_4$. Add the paper, and finish the titration to a faint pink with the standard $KMnO_4$.

(*b*) *Calculation.*—Calculate the total calcium as percentage of $CaCl_2$, as follows:

$$\text{Percentage of } CaCl_2 = \frac{\text{ml. of 0.1 } N \text{ } KMnO_4 \times 11.1}{\text{wt. of original sample in grams}}$$

The calculated percentage of $CaCl_2$ shall be corrected for $Ca(OH)_2$ and $CaCO_3$.

Total Alkalinity and Magnesium Compounds

3. (*a*) Weigh accurately a 10.00-g. sample (Note 1), place in a 400-ml. beaker, and dissolve in 25 ml. of water. Add a drop of phenolphthalein indicator, and titrate with 0.1 *N* HCl until the brilliant pink color fades or becomes a

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1932 to 1934. Editorially revised and rearranged in 1939.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

dull, slowly-returning color when tested by adding another drop or two of indicator. Then add enough of the 0.1 *N* HCl in excess to give a permanent red color after the addition of a drop of methyl orange indicator. Titrate back to the neutral point with 0.1 *N* NaOH and adjust to a faint pink color with 0.1 *N* HCl. Use these solutions for the subsequent determination of magnesium compounds.

(*b*) The net volume of acid used is sometimes calculated as calcium hydroxide for convenience, as follows:

Percentage of $Ca(OH)_2$ =

ml. of 0.1 *N* HCl × 0.0037 × 10

(*c*) To the neutral solutions add 9 ml. of 1 *N* NaOH which will precipitate $Mg(OH)_2$ along with some $Ca(OH)_2$. Filter the precipitate and transfer as much as possible to the filter. Dissolve the precipitate from the paper to the original beaker with about 10 ml. of HCl (1:1). Add 30 ml. of cold saturated NH_4Cl. With a volume of about 150 ml., heat to boiling and add from 50 to 60 ml. (or an excess) of cold saturated $(NH_4)_2C_2O_4$. Heat just to boiling while stirring, and slowly make alkaline with diluted NH_4OH. Let stand 10 to 15 min. and filter through a retentive qualitative paper such as Whatman's No. 2 or 3. Save this filtrate. Return the precipitate to the original beaker, dissolve in HCl (1:1) as before, add 15 ml. of cold saturated NH_4Cl and 10 ml. of the $(NH_4)_2C_2O_4$, heat to boiling, and slowly make alkaline with diluted NH_4OH. When the precipitate is well formed and settles readily, filter as before, and combine the two perfectly clear filtrates. Concentrate to about 250 ml. If much magnesium is present, the oxalate may precipitate. Add HCl to dissolve it. At a temperature of approximately 70 C., slowly add 10 ml. of $(NH_4)_2HPO_4$ (15 per cent). Add NH_4OH (sp.gr. 0.90) slowly until the precipitate is formed, then add excess. Let stand over night, stirring vigorously several times and also just before filtering. Filter through a Gooch crucible or a No. 42 Whatman paper, or paper of equivalent quality, and wash with cold NH_4OH (1:10). Ignite to constant weight and weigh as $Mg_2P_2O_7$. If the alkalinity is appreciable and the total magnesium low, this should be calculated as $Mg(OH)_2$. Any balance of magnesium over total alkalinity would be $MgCl_2$.

(*d*) *Calculations.*—Calculate the percentage of $Mg(OH)_2$ as follows:

Percentage of $Mg(OH)_2$ =

grams of $Mg_2P_2O_7$ × 0.524 × 10

Percentage of $Mg(OH)_2$ × 34.3 =

ml. of 0.1 *N* HCl due to $Mg(OH)_2$

If the alkalinity titration with phenolphthalein was stopped and the milliliters recorded with the brilliant pink faded, the milliliters represent actual $Ca(OH)_2$ present, as follows:

Percentage of $Ca(OH)_2$ =

ml. of 0.1 *N* HCl × 0.0037 × 10

The difference (milliliters for methyl orange end point minus milliliters for phenolphthalein end point) minus milliliters due to $Mg(OH)_2$ equals the milliliters due to $CaCO_3$, as follows:

Percentage of $CaCO_3$ =

ml. of 0.1 *N* HCl due to $CaCO_3$ × 0.0050 × 10

Percentage as $CaCl_2$ =

(ml. for $Ca(OH)_2$ + ml. for $CaCO_3$) ×

0.00555 × 10

Deduct this latter percentage from total calcium as net $CaCl_2$.

NOTE.—If a large amount of $MgCl_2$ (2 or 3 per cent) is present, the calculation of $CaCO_3$ will be inaccurate.

Total Alkali Chlorides as Sodium Chloride

4. (*a*) The chlorides KCl and NaCl shall be determined together. Where it is desired to distinguish between them, the potassium may be determined by any standard method and the two reported separately. The perchlorate method may be used for this determination. For routine work the KCl and NaCl shall be reported as percentage of NaCl. The method used shall be as follows:

Dissolve an 8.000-g. sample (Note 1) in 50 ml. of hot water, add 1 g. of c.p. $Ca(OH)_2$, mix well, and boil gently for 1 min. Dilute to exactly 100 ml. in a volumetric flask. Filter through a dry paper, discarding the first 10 ml., pipette a 25.00-ml. aliquot, add 20 ml. of water; heat to boiling and add 50 ml. of hot $(NH_4)_2C_2O_4$ (5 per cent) or $(NH_4)_2CO_3$ (4 per cent)—preferably the latter. Dilute to 100 ml. and mix well. Let stand until the temperature is about that of the room and adjust the volume.

(*b*) Finally, filter through a dry retentive filter paper, discarding the first 10 ml. and refiltering if cloudy. Pipette a 25.00-ml. aliquot in a 250-ml. beaker and add 1 ml. of HCl (sp.gr. 1.19). Evaporate to dryness on a steam bath. Thoroughly ignite in a muffle or heat-treating furnace (Note 2) at 300 to 350 C. In about 30 min., organic and ammonium salts should have been driven off. Cool, dissolve in 10 ml. of water, add 3 drops of Na_2CrO_4 or K_2CrO_4 (5 per cent) solution as indicator, and titrate with 0.02 *N* $AgNO_3$ (Note 3) to a pink end point. If the ignition was correctly done, there will be but little brown or yellow coloration due to charred organic residue to interfere with seeing the end point. Run a blank on the reagents used. If this is less than 0.5 ml. neglect it, if over 0.5 ml. subtract from the titration after deducting 0.5 ml. (1.00 ml. of 0.02 *N* $AgNO_3$ is equivalent to 0.00117 g. NaCl). In the method as given, 0.5000 g. of sample is finally titrated.

(*c*) *Calculation.*—Calculate the total alkali chlorides as sodium chloride, as follows:

$$\text{Percentage of NaCl} = \frac{\text{ml. of 0.02 } N \text{ } AgNO_3 \times 0.00117 \times 1.05 \times 100}{0.5000}$$

or

$$\text{Percentage of NaCl} = \text{ml. of 0.02 } N \text{ } AgNO_3 \times 0.246$$

RAPID TECHNICAL METHOD

5. (*a*) For ordinary purposes, where the quantity of material purchased does not warrant the employment of the foregoing method of analysis, calcium chloride is deemed as satisfactory if the total chlorides present, determined by titration with 0.1 *N* $AgNO_3$ and calculated to $CaCl_2$, is in excess of 78 per cent and if not more than a slight precipitate of $Mg(OH)_2$ appears when a 10 per cent filtered solution of the material is made alkaline with NH_4OH.

(*b*) No material shall be rejected under this technical method of analysis, and in case the calcium chloride tested by this rapid procedure does not conform to the specifications, it shall be analyzed by the methods described in Sections 2 to 4, inclusive.

EXPLANATORY NOTES

NOTE 1.—Instead of weighing out separate samples as indicated in Sections 2, 3, and 4, a 25-g. sample may be diluted to a volume of 100 ml., and 1 ml. of this solution used for the procedure in Section 2, 40 ml. for the procedure in Section 3, and 32 ml. for the procedure in

Section 4. The 1 ml. should be measured with a standard calibrated pipette, and the 40 ml. and 32 ml. with a burette. These volumes shall then be further diluted to conform to the concentrations indicated under Sections 2, 3, and 4. This handling will render accurate distribution of the insoluble $Mg(OH)_2$ and $CaCO_3$ present more difficult than using direct weighed samples.

Instead of weighing accurately a 10.00-g. sample, a sample of approximately 10 g. may be used if desired, in which case the percentage of $Ca(OH)_2$ may be calculated as follows:

$$\text{Percentage of } Ca(OH)_2 = \frac{\text{ml. of 0.1 } N \text{ HCl} \times 0.0037 \times 100}{\text{wt. of sample in grams}}$$

NOTE 2.—In case a muffle or furnace with close heat control is not available, a moderate bunsen flame played over the beaker may be used to volatilize the ammonium and organic compounds. In this case it would be advisable to control the determination by means of a known mixture having NaCl present in the same magnitude.

NOTE 3.—The 0.02 N $AgNO_3$ may be conveniently made by diluting 50.00 ml. of exactly 0.1 N solution to a 250-ml. volume. There is an empirical correction to be made on the factor which amounts to the 0.02 N value multiplied by about 1.05. This can be determined exactly by running on known mixtures having the same magnitude composition as the calcium chloride to be analyzed.

Standard Specifications for

SLOW-SETTING EMULSIFIED ASPHALT[1]

FOR FINE AGGREGATE MIXES

A.S.T.M. Designation: D 631 – 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 631; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover a slow-setting emulsified asphalt for fine aggregate mixes in which a substantial quantity of aggregate passes a $\frac{1}{8}$-in. sieve and a portion may pass a No. 200 (74-micron) sieve.

Properties and Tests

2. (*a*) Emulsified asphalt shall be homogeneous. It shall show no separation of asphalt after thorough mixing, within 30 days after delivery, provided separation has not been caused by freezing.

(*b*) Emulsified asphalt (slow-setting) for fine aggregate mixes shall conform to the following requirements:

Viscosity, Saybolt Furol, 60 ml. at 25 C. (77 F.)	not less than 20 sec., and not more than 100 sec.
Residue by evaporation at 163 C. (325 F.) or by distillation	not less than 57 per cent, and not more than 62 per cent
Sieve test	not more than 0.05 per cent
Modified miscibility with water[a]	difference of asphalt residue not more than 4.5 per cent
Cement mixing test	not more than 2.0 per cent

[a] If the sample of emulsified asphalt being tested fails to conform to this requirement for modified miscibility, the sample shall be tested for 5-day settlement and for miscibility, and if the numerical difference between the average percentages of asphaltic residue in the 5-day settlement test is less than 3, and if the standard miscibility test shows no appreciable coagulation in 2 hr., then the emulsified asphalt shall be considered as conforming to these specifications and shall be accepted.

(*c*) *Residue.*—The residue obtained from evaporation or distillation shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec.	100 to 200
Soluble in carbon disulfide:	
Petroleum asphalts	not less than 97.0 per cent
Native asphalts	not less than 95 per cent
Ash	not more than 2 per cent
Ductility at 25 C. (77 F.)	not less than 60 cm.
Specific gravity at 25 C. (77 F.)	not less than 1.00

Basis of Purchase

3. Prior to the award of the order or contract, a sample may be tested by the purchaser, and if it fails to comply with the specification requirements, the bid accompanying the sample shall be rejected. Prior to any shipments being made on projects requiring 20,000 gal. or more, a sample shall be taken, under

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1941 to 1943.

the supervision of the purchaser, from a lot of not less than 20,000 gal. of the emulsified asphalt and shall be kept in a clean, airtight, sealed container at a temperature of not less than 4 C. (40 F.) until tested.

Sampling

4. At least one sample of not less than 1 gal. shall be taken from each lot or shipment of the emulsified asphalt after arrival at its destination. The samples shall be stored in clean, airtight containers at a temperature of not less than 4 C. (40 F.) until tested.

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the Standard Methods of Testing Emulsified Asphalts (A.S.T.M. Designation: D 244) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

MEDIUM-SETTING EMULSIFIED ASPHALT[1]

FOR COARSE AGGREGATE PLANT MIXES

A.S.T.M. Designation: D 397 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 397; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover a medium-consistency emulsified asphalt for plant mixes with coarse aggregate, substantially all of which is retained on a $\frac{1}{8}$-in. sieve and with practically no material passing a No. 200 (74-micron) sieve.

Properties and Tests

2. (*a*) Emulsified asphalt shall be homogeneous. It shall show no separation of asphalt after thorough mixing, within 30 days after delivery, provided separation has not been caused by freezing.

(*b*) Emulsified asphalt for coarse aggregate plant mixes shall conform to the following requirements:

Viscosity, Saybolt Furol, 60 ml. at 25 C. (77 F.)	not less than 100 sec.
Residue by distillation	not less than 60 per cent, and not more than 65 per cent
Settlement, 5 days	not more than 5
Demulsibility,[a] 50 ml. of 0.10 *N* $CaCl_2$	not more than 30 per cent
Sieve test	not more than 0.10 per cent
Miscibility with water	no appreciable coagulation in 2 hr.
Coating test	it shall not show appreciable separation when mixed with washed, dry, clean stone for 3 min. and shall coat the stone thoroughly.

[a] The demulsibility test shall be made within 30 days from date of shipment.

(*c*) *Residue.*—The residue obtained from distillation shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec.	100 to 200
Soluble in carbon disulfide:	
Petroleum asphalts	not less than 97.5 per cent
Native asphalts	not less than 95 per cent
Ash	not more than 2 per cent
Ductility at 25 C. (77 F.)	not less than 40 cm.
Specific gravity at 25 C. (77 F.)	not less than 1.00

Basis of Purchase

3. Prior to the award of the order or contract, a sample may be tested by the purchaser and if it fails to comply with the specification requirements, the bid accompanying the sample shall be rejected. Prior to any shipments being made on projects requiring 20,000 gal. or more, a sample shall be taken, under the supervision of the purchaser, from

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1934 to 1939, being revised in 1936 and 1939.

a lot of not less than 20,000 gal. of the emulsified asphalt and shall be kept in a clean, airtight, sealed container at a temperature of not less than 4 C. (40 F.) until tested.

Sampling

4. At least one sample of not less than 1 gal. shall be taken from each lot or shipment of the emulsified asphalt after arrival at its destination. The samples shall be stored in clean, airtight containers at a temperature of not less than 4 C. (40 F.) until tested.

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the Standard Methods of Testing Emulsified Asphalts (A.S.T.M. Designation: D 244) of the American Society for Testing Materials.[3]

Standard Specifications for

MEDIUM-SETTING EMULSIFIED ASPHALT[1]

FOR RETREAD AND COARSE AGGREGATE MIXES

A.S.T.M. Designation: D 398 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 398; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover a low-consistency emulsified asphalt for retread mixes with coarse aggregate, substantially all of which is retained on a $\frac{1}{8}$-in. sieve and with practically no material passing a No. 200 (74-micron) sieve.

Properties and Tests

2. (*a*) Emulsified asphalt shall be homogeneous. It shall show no separation of asphalt after thorough mixing, within 30 days after delivery, provided separation has not been caused by freezing.

(*b*) Emulsified asphalt for retread and coarse aggregate mixes shall conform to the following requirements:

Viscosity, Saybolt Furol, 60 ml. at 25 C. (77 F.)	not less than 20 sec., and not more than 100 sec.
Residue by distillation	not less than 55 per cent, and not more than 60 per cent
Settlement, 5 days	not more than 5
Demulsibility,[a] 50 ml. of 0.10 *N* $CaCl_2$	not more than 30 per cent
Sieve test	not more than 0.10 per cent
Miscibility with water	no appreciable coagulation in 2 hr.
Coating test	it shall not show appreciable separation when mixed with washed, dry, clean stone for 3 min. and shall coat the stone thoroughly.

[a] The demulsibility test shall be made within 30 days from date of shipment.

(*c*) *Residue.*—The residue obtained from distillation shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec.	100 to 200
Soluble in carbon disulfide:	
Petroleum asphalts	not less than 97.5 per cent
Native asphalts	not less than 93 per cent
Ash	not more than 2 per cent
Ductility at 25 C. (77 F.)	not less than 40 cm.
Specific gravity at 25 C. (77 F.)	not less than 1.00

Basis of Purchase

3. Prior to the award of the order or contract, a sample may be tested by the purchaser and if it fails to comply with the specification requirements, the bid accompanying the sample shall be rejected. Prior to any shipments being made on projects requiring 20,000 gal. or more, a sample shall be taken, under

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1934 to 1939, being revised in 1939.

the supervision of the purchaser, from a lot of not less than 20,000 gal. of the emulsified asphalt and shall be kept in a clean, airtight, sealed container at a temperature of not less than 4 C. (40 F.) until tested.

Sampling

4. At least one sample of not less than 1 gal. shall be taken from each lot or shipment of the emulsified asphalt after arrival at its destination. The samples shall be stored in clean, airtight containers at a temperature of not less than 4 C. (40 F.) until tested.

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the Standard Methods of Testing Emulsified Asphalts (A.S.T.M. Designation: D 244) of the American Society for Testing Materials.[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

MEDIUM-SETTING EMULSIFIED ASPHALT[1]

HEAVY PREMIX—SUMMER GRADE

A.S.T.M. Designation: D 399 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 399; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover a high-consistency heavy-premix grade of emulsified asphalt, for plant mix or patching with coarse aggregate, substantially all of which is retained on a $\frac{1}{8}$-in. sieve and with practically no material passing a No. 200 (74-micron) sieve.

Properties and Tests

2. (*a*) Emulsified asphalt shall be homogeneous. It shall show no separation of asphalt after thorough mixing, within 30 days after delivery, provided separation has not been caused by freezing.

(*b*) Emulsified asphalt (heavy premix—summer grade) shall conform to the following requirements:

Residue by distillation	not less than 65 per cent
Sieve test	not more than 0.10 per cent
Miscibility with water	no appreciable coagulation in 2 hr.
Coating test	it shall not show appreciable separation when mixed with washed, dry, clean stone for 3 min. and shall coat the stone thoroughly.

(*c*) *Residue.*—The residue obtained from distillation shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec	100 to 200
Soluble in carbon disulfide:	
Petroleum asphalts	not less than 97.5 per cent
Native asphalts	not less than 95 per cent
Ash	not more than 2 per cent
Ductility at 25 C. (77 F.)	not less than 40 cm.
Specific gravity at 25 C. (77 F.)	not less than 1.00

Basis of Purchase

3. Prior to the award of the order or contract, a sample may be tested by the purchaser and if it fails to comply with the specification requirements, the bid accompanying the sample shall be rejected. Prior to any shipments being made on projects requiring 20,000 gal. or more, a sample shall be taken, under the supervision of the purchaser, from a lot of not less than 20,000 gal. of the emulsified asphalt and shall be kept in a clean, airtight, sealed container at a temperature of not less than 4 C. (40 F.) until tested.

Sampling

4. At least one sample of not less than 1 gal. shall be taken from each lot or shipment of the emulsified asphalt after

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1934 to 1939, being revised in 1936 and 1939.

arrival at its destination. The samples shall be stored in clean, airtight containers at a temperature of not less than 4 C. (40 F.) until tested.

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the Standard Methods of Testing Emulsified Asphalts (A.S.T.M. Designation: D 244) of the American Society for Testing Materials.[3]

Standard Specifications for

QUICK-SETTING EMULSIFIED ASPHALT[1]

FOR PENETRATION AND SURFACE TREATMENT

A.S.T.M. Designation: D 401 – 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 401; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover emulsified asphalt (quick-setting) for penetration and surface treatment.

Properties and Tests

2. (*a*) Emulsified asphalt shall be homogeneous. It shall show no separation of asphalt after thorough mixing, within 30 days after delivery, provided separation has not been caused by freezing.

(*b*) Emulsified asphalt (quick-setting) for penetration and surface treatment shall conform to the following requirements:

Viscosity, Saybolt Furol, 60 ml. at 25 C. (77 F.)	not less than 20 sec., and not more than 100 sec.
Residue by distillation	not less than 55 per cent, and not more than 60 per cent
Settlement, 5 days	not more than 3
Demulsibility,[a] 35 ml. of 0.02 *N* $CaCl_2$	not less than 60 per cent
Sieve test	not more than 0.10 per cent

[a] The demulsibility test shall be made within 30 days from date of shipment.

(*c*) *Residue.*—The residue obtained from distillation shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec.	100 to 200
Soluble in carbon disulfide:	
Petroleum asphalts	not less than 97.5 per cent
Native asphalts	not less than 95 per cent
Ash	not more than 2 per cent
Ductility at 25 C. (77 F.)	not less than 40 cm.
Specific gravity at 25 C. (77 F.)	not less than 1.00

Basis of Purchase

3. Prior to the award of the order or contract, a sample may be tested by the purchaser and if it fails to comply with the specification requirements, the bid accompanying the sample shall be rejected. Prior to any shipments being made on projects requiring 20,000 gal. or more, a sample shall be taken, under the supervision of the purchaser, from a lot of not less than 20,000, gal. of the emulsified asphalt and shall be kept in a clean, airtight, sealed, glass or black iron container at a temperature of not less than 4 C. (40 F.) until tested.

Sampling

4. At least one sample of not less than 1 gal. shall be taken from each lot or shipment of the emulsified asphalt after arrival at its destination. The samples

Standard Specifications for

ASPHALT FILLER FOR BRICK PAVEMENTS[1]

A.S.T.M. Designation: D 241 – 43

ADOPTED, 1943.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 241; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphalt filler for brick pavements.

General Requirements

2. The asphalt filler shall be free from water and shall not foam when heated to a temperature of 177 C. (350 F.) for grade A, or 230 C. (446 F.) for grade B. Grade B is the low-exuding type.

Properties

3. The filler shall conform to the requirements prescribed in Table I.

Methods of Testing

4. The material shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

TABLE I.—REQUIREMENTS FOR ASPHALT FILLER.

	Grade A		Grade B	
	Min.	Max.	Min.	Max.
Softening point (ring-and-ball method)	167 F. (75 C.)	185 F. (85 C.)	214 F. (101 C.)	230 F. (110 C.)
Flash point (Cleveland open cup)	469 F. (243 C.)	....	482 F. (250 C.)	....
Penetration:				
0 C. (32 F.), 200 g., 1 min	15	....	12	....
25 C. (77 F.), 100 g., 5 sec	30	40	23	32
46 C. (115 F.), 50 g., 5 sec	....	80	....	47
Ductility at 25 C. (77 F.), (5 cm. per min.), cm.	3	....	1.5	....
Loss on heating at 163 C. (325 F.), 50 g., 5 hr., per cent	....	1.0	....	0.3
Total bitumen soluble in carbon disulfide, per cent	99.0	....	99.3	....
Proportion of bitumen soluble in carbon tetrachloride, per cent	99.0	....	99.3	....

(*a*) *Sampling.*—Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140).[3]

(*b*) *Softening Point.*—Standard Method of Test for Softening Point of Bituminous Materials (Ring-and-Ball Method) (A.S.T.M. Designation: D 36).[3]

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1926 to 1943, being revised in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*c*) *Flash Point.*—Standard Method of Test for Flash and Fire Points by Means of Open Cup (A.S.T.M. Designation: D 92).[3]

(*d*) *Penetration.*—Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5).[3]

(*e*) *Loss on Heating.*—Tentative Method of Test for Loss on Heating of Oil and Asphaltic Compounds (A.S.T.M. Designation: D 6).[3]

(*f*) *Ductility.*—Standard Method of Test for Ductility of Bituminous Materials (A.S.T.M. Designation: D 113).[3]

(*g*) *Bitumen Soluble in Carbon Disulfide.*—Standard Method of Test for Determination of Bitumen (A.S.T.M. Designation: D 4).[3]

(*h*) *Bitumen Soluble in Carbon Tetrachloride.*—Standard Method of Test for Proportion of Bitumen Soluble in Carbon Tetrachloride (A.S.T.M. Designation: D 165).[3]

Standard Specifications for
COAL-TAR PITCH FOR STONE BLOCK FILLER[1]

A.S.T.M. Designation: D 112 – 30

ADOPTED, 1930.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 112; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover coal-tar pitch suitable for use as a filler between stone block in pavements.

Properties

2. The coal-tar pitch shall conform to the following requirements:

Water	0.00 per cent
Softening point (cube-in-water method)	46 to 57 C. (115 to 135 F.)[a]
Distillation test:	
Total distillate by weight, 0 to 300 C. (32 to 572 F.)	14.00 per cent, max.
Residue by weight	86.00 per cent, min.
Specific gravity at 38 C. (100.4 F.) of total distillate to 300 C. (572 F.)	1.02 min.
Softening point (cube-in-water method) of residue from distillation test	75 C. (167 F.), max.
Ductility at 50 to 100 penetration,[b] at 25 C. (77 F.)	50 cm., min.
Total bitumen (soluble in carbon disulfide)	65.0 to 80.0 per cent

[a] The softening point (cube-in-water method) specified should have a range of not over 10 F. within the above limits. The range, within the limits of 46 to 57 C. (115 to 135 F.) should vary with the use of the material, for example, if used in admixture with sand, in a northern locality or a southern locality. The softening point range within the above limits, should also vary according to the character of the paving.

[b] The penetration of the pitch shall be brought within the range of 50 to 100 penetration by heating in an open vessel with frequent stirrings at a temperature of not over 350 F.

Methods of Testing

3. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Percentage of Water.*—Standard Method of Test for Water in Petroleum Products and Other Bituminous Materials (A.S.T.M. Designation: D 95).[3]

(*b*) *Softening Point.*—Standard Method of Test for Softening Point of Tar Products (Cube-in-Water Method) (A.S.T.M. Designation: D 61).[3]

(*c*) *Distillation.*—Standard Method of Test for Distillation of Tar Products Suitable for Road Treatment (A.S.T.M. Designation: D 20).[3]

(*d*) *Ductility.*—Standard Method of Test for Ductility of Bituminous Materials (A.S.T.M. Designation: D 113).[3]

(*e*) *Total Bitumen.*—Standard Method of Test for Determination of Bitumen (A.S.T.M. Designation: D 4).[3]

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1921 to 1930, being revised in 1922, 1923, and 1927. Editorially revised and rearranged in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

ASPHALT PLANK[1]

A.S.T.M. Designation: D 517 – 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 517; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphalt plank of two types as used for bridge floors:

(*a*) Plain asphalt plank, and

(*b*) Mineral-surfaced asphalt plank.

NOTE.—Plain asphalt plank conforming to these specifications are also suitable for waterproofing protection where a solid bridge floor carries ballasted railroad track.

Manufacture

2. Asphalt plank shall be formed by the extrusion of a mixture of asphalt, fiber, and mineral aggregate under sufficient pressure to expel the entrapped air and form a dense mass.

Mineral Surfacing

3. In the case of mineral-surfaced asphalt plank, at least 15 oz. per sq. ft. of tough, hard, durable, coarse aggregate (well-graded from No. 4 (4760-micron)[3] to ¾ in. square-opening sieves) shall be embedded under pressure into one surface of the freshly-extruded hot plank to such a depth that none extends above the intended wearing surface. The top surface of the mineral surfacing shall not be covered with the matrix of the plank proper.

Workmanship

4. The asphalt plank shall be free from defects affecting its serviceability and appearance; it shall have straight edges and square corners.

Asphalt Cement

5. The asphalt cement shall have such characteristics that, when combined with the other ingredients, a plank of desired quality will result.

Fiber

6. The fibrous material shall consist of finely divided whole threads or fiber free from lumps, and when used it shall be in a flocculent condition. This fabric and fibrous material shall be free from all foreign materials such as metal, leather, straw, sawdust, cornstalks, or other deleterious materials.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1938 to 1940.

[3] Detailed requirements for this sieve are given in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Mineral Filler

7. The mineral filler shall consist of finely crushed slate, limestone, asbestos, silica, or other aggregate which has been proven suitable for use with asphalt cement in constructing pavement wearing surfaces.

Dimensions

8. Asphalt plank shall have the dimensions specified or shown on the plans. Tolerances of plus or minus $\frac{1}{16}$ in. in thickness, plus or minus $\frac{1}{8}$ in. in width, and plus or minus $\frac{1}{4}$ in. in length will be permitted.

NOTE.—The following thicknesses are recognized as standard: $\frac{3}{4}$ in., 1 in., $1\frac{1}{4}$ in.,$1\frac{1}{2}$ in., and 2 in.

Absorption

9. The absorption of asphalt plank shall not exceed 1.0 per cent by weight.

Brittleness

10. At least 80 per cent of the specimens of each thickness of plank tested shall not show any detrimental cracking when tested in accordance with the method described in Section 16.

Indentation

11. The indentation of asphalt plank, irrespective of thickness, when subjected to the loads prescribed in Section 17, shall be within the following limits:

(*a*) *At 77 F. (25 C.), at the end of 1 min.*—Not less than 12 mils nor more than 27 mils.

(*b*) *At 77 F. (25 C.), at the end of 10 min.*—Not more than that specified in the following table, corresponding to the indentation at 1 min.:

Indentation Recorded at 1 min., mils (to the nearest 1 mil)	Maximum Indentation at 10 min., mils (to the nearest 0.5 mil)
12	21.5
13	23.0
14	24.0
15	25.5
16	27.0
17	28.5
18	30.0
19	31.0
20	32.5
21	33.5
22	35.0
23	36.5
24	37.5
25	39.0
26	40.0
27	41.5

(*c*) *At 125 F. (51.7 C.), at the end of 30 sec.*—Not less than 35 mils nor more than 70 mils.

(*d*) *At 125 F. (51.7 C.), at the end of 300* sec.—Not more than that specified in the following table (or interpolated therefrom) corresponding to the indentation at 30 sec.:

Indentation Recorded at 30 sec., mils (to the nearest 1 mil)	Maximum Indentation at 300 sec., mils (to the nearest 0.5 mil)
35	70.0
40	77.0
45	85.0
50	93.0
55	100.0
60	108.0
65	116.0
70	125.0

SAMPLING AND METHODS OF TESTING

Sampling

12. For purpose of tests, three planks shall be taken at random by the purchaser for each 1000 planks, or fraction thereof, of each thickness included in the shipment.

Inspection

13. Plank from each lot shall be examined for appearance, straightness of edges, and squareness of corners, and measured for width and length. They shall also be calipered at four scattered points each, with a micrometer having flat bearing surfaces at both contact points of not less than $\frac{1}{4}$ in. in diameter. The average of the readings shall be considered the thickness of the plank.

Weight of Mineral Surfacing

14. The weight of mineral aggregate shall be determined by removing the mineral surfacing aggregate from not less than 1 sq. ft. of mineral surfaced asphalt plank. The aggregate shall be cleaned with any suitable solvent, dried, and sieved on a No. 8 (2380-micron) sieve.[3] The amount of aggregate on the sieve shall be weighed and the weight of aggregate per square foot determined.

Absorption Test

15. A specimen 2 by 6 in. shall be cut from the asphalt plank in such a manner that all edges are freshly cut. The specimen shall be accurately weighed to the nearest 0.10 g., immersed in water

TABLE I.—NAIL SIZES REQUIRED FOR BRITTLENESS TEST.

Thickness of Asphalt Plank, in.	Nail Size	A.S.&W. Gage No.	Diameter, in.
¾	12 d.	9	0.148
1	16 d.	8	0.162
1½	20 d.	6	0.192
1¾	30 d.	5	0.207
2	30 d.	5	0.207

for 24 hr., removed, and the surface water wiped off with a slightly dampened cloth. The specimen shall then be weighed to the nearest 0.10 g. and the percentage of absorption determined. The time elapsing between the removal of the specimen from the bath and its weighing shall not exceed 1 min.

Brittleness Test

16. Two 6 by 6-in. specimens shall be cut from each of the three sample planks selected in accordance with Section 12. Five of these specimens shall be tested as follows: The specimens shall be immersed in a water bath and maintained at a temperature of 39 to 43 F. (4 to 6 C.) for not less than 3 hr., and then tested immediately upon their removal from the water bath. A smooth, common nail of the size specified in Table I shall be driven into the face at each of two diagonally opposite corners of the specimen not less than 1½ in. nor more than 2 in. from each edge, but not directly over a piece of mineral surfacing aggregate. The specimen shall be supported over its entire base with a timber block 7 by 7 by 1½ in. and the nails shall be driven vertically with repeated blows from a 10-lb. weight falling freely from a constant height of 20 in. above the level of the initial top of the nail or striking assembly. The height shall not be adjusted to compensate for the increased fall caused by the penetration of the nail. The nails shall be supported by a collar or other similar assembly that will hold the nail in a vertical position without friction. Should a nail strike a piece of aggregate covered by the planking matrix, as shown by bending of the nail or by its deflection from the vertical, the specimen shall be discarded and the test repeated on a new specimen. The nails shall penetrate through the asphalt plank, without detrimental cracking, to a depth of not less than 1 in. into the timber block. Cracking shall be considered detrimental when the cracks extend to a point nearer than ½ in. to an edge.

Indentation Test

17. Two 6 by 6-in. specimens from each set of sample planks selected in accordance with Section 12 shall be subjected to the following indentation tests: The specimens shall be brought to a temperature of 77 ± 1 F. (25 ± 0.5 C.) by immersing them in a water bath at this temperature for not less than 2 hr. nor more than 4 hr. Specimens shall also be immersed in water at this temperature during the test. A rod or needle with a hemispherical end 1 in. in diameter shall be applied to the surface (in case of mineral-surfaced

plank, the test surface of the specimen shall be the face that does not contain mineral surfacing aggregate) of the specimen with a load of 2 lb., the specimen being supported on a polished steel plate.[4] The indentation indicating micrometer dial shall be adjusted to zero and an additional load of 28 lb. applied to the rod or needle. The transfer of the 28-lb. load to the rod shall be completed within 10 sec. following the zero adjustment of the micrometer dial. The readings of the dial at the end of 1 min. and 10 min. from the time of application of the total load shall be taken as the measure of indentation. The 1-min. and 10-min. indentation readings shall be taken at three scattered points on each specimen. The average of the three sets of readings shall be recorded as the 1-min. and 10-min. indentations. The test shall be repeated at 125 ± 1 F. (51.7 ± 0.5 C.), the readings at three points being taken at the end of 30 sec. and 300 sec. If the average indentation of either specimen (or more than one single reading of the three made at each time period) measured as specified above fails to meet the specified requirements in any test, the plank represented by the sample shall be considered to have failed.

[4] The indentation test may be made with relatively simple apparatus which can be constructed with little expense in almost any laboratory. Where convenience and portability of the indentation apparatus are particularly desirable, the portable indenter devised by J. W. McBurney for indentation testing of asphalt tile (J. W. McBurney, "Indentation of Asphalt Tile," *Proceedings*, Am. Soc. Testing Mats, Vol. 34, Part II, p. 591 (1934)) complies with all the above stated requirements for apparatus to make the test. Adaptation of the McBurney indentation test method to asphalt plank has been described in a paper by H. W. Greider and Henri Marc, "Indentation and Compression Shear Tests for Determining Service Stability of Asphalt Plank," *Proceedings*, Am. Soc. Testing Mats., Vol. 37, Part II, p. 530 (1937).

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.3-1943

Standard Method of Test for

DETERMINATION OF BITUMEN[1]

A.S.T.M. Designation: D 4 – 42

ADOPTED, 1927; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 4; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the determination of bitumen in materials containing at least 25 per cent bitumen. Bitumen may usually be expeditiously and accurately determined by method No. 1, Section 5. In the case of certain native asphalts containing finely divided mineral matter, the mineral residue is not easily retained by the filter and it is necessary to use method No. 2, Section 6, in order to obtain accurate results. Method No. 2 shall not be used unless the filter clogs unduly or unless the mineral matter passing through the filter exceeds 0.5 per cent.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Gooch Crucible*, approximately 4.4 cm. in width at the top, tapering to 3.6 cm. at the bottom, with a depth of 2.5 cm.

(*b*) *Asbestos* (amphibole), Gooch grade, acid washed, cut in pieces not exceeding 1 cm. in length, shredded, and shaken up with water.

(*c*) *Flasks.*—Two 125-ml. conical flasks such as Erlenmeyer flasks.

(*d*) *Filtering Flask.*

(*e*) *Filter Tube.*

(*f*) *Section of Rubber Tubing*, to hold the Gooch crucible on the filter tube.

(*g*) *Drying Oven.*

(*h*) *Bunsen Burner.*

(*i*) *Suction Pump.*

(*j*) *Analytical Balance.*

(*k*) *Desiccator.*

Preparation of Sample

3. The sample shall be representative, and if it contains more than 2 per cent of water it shall be dehydrated by distillation in a copper still in accordance with the Standard Method of Test for Water in Creosote (A.S.T.M. Designation: D 370) of the American Society for Testing Materials,[3] and the water-free distillate returned to the residue.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to its present adoption as standard, this method was published as standard from 1911 to 1923, but withdrawn and republished as tentative from 1923 to 1927, being revised in 1926 and 1927.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

If the material is hard and brittle, it may be ground, and dried at a temperature below the temperature of volatilization of the material.

Preparation of Gooch Crucible

4. Insert the filter tube in the stopper of the filtering flask, set the Gooch crucible in the filter tube, and connect the flask to the suction pump. Fill the crucible with some of the suspension of asbestos in water, allow it partly to settle in the crucible, and apply a light suction to draw off the water, leaving a firm mat of asbestos in the crucible. Add more suspended asbestos and repeat the process until a mat is built up that weighs 0.5 ± 0.1 g. after ignition (Note). Wash the asbestos mat thoroughly with water, dry in the oven and ignite over a bunsen burner. Cool the crucible in the desiccator, weigh, and replace it in the dry filter tube supported in the clean, dry filtering flask.

NOTE.—In the determination, the asbestos apparently adsorbs irreversibly a small amount of soluble bitumen (usually 1 to 5 mg. per gram of asbestos) which is not removed by subsequent washing with solvent. The weight of asbestos used, therefore, should be kept within the specified limits to insure reproducible results.

Method No. 1

Procedure

5. (*a*) Weigh approximately 2 g. of the sample into a tared conical flask, and add 100 ml. of c.p. carbon disulfide to the flask in small portions with continued agitation until all lumps disappear and nothing adheres to the bottom of the flask. Then stopper the flask and set aside for 15 min.

(*b*) Decant the carbon disulfide solution carefully through the asbestos mat in the prepared Gooch crucible, with or without light suction as may be necessary, retaining as much of the sediment as possible in the conical flask until the solution has drained through the mat. With a small amount of carbon disulfide wash down the sides of the flask and transfer the sediment and precipitate from the flask to the asbestos mat. The flask may be scrubbed with a feather if necessary in order to remove all of the precipitate. Wash the contents of the crucible with carbon disulfide until the washings are colorless, then apply suction to remove the carbon disulfide. Dry the crucible in the oven at 100 to 125 C. for 20 min., cool in the desiccator, and weigh. The increase in weight over the original weight is the weight of matter insoluble in carbon disulfide. Ignite the crucible at a red heat and after thorough ignition, cool, and weigh. The weight of the insoluble matter after ignition is the weight of ash.

(*c*) If insoluble matter adheres to the flask, dry the flask, and weigh. Add the increase in weight over the original weight to the weight of insoluble matter in the Gooch crucible.

(*d*) In case there is any question involving the amount of mineral matter that may have passed through the filter, evaporate the filtrate, and burn the bituminous residue. If a carbonate mineral is present in the filtrate ash, add to the ash a few drops of ammonium carbonate solution, and dry at 100 C., then heat for a few minutes to a dull red heat, and cool in the desiccator. Weigh, and add the weight of ash obtained to the weight of matter insoluble in carbon disulfide.

NOTE.—In the event that water-soluble salts which are insoluble in carbon disulfide are present, the amount of these salts may be determined in accordance with the procedure described in the 1937 Report of Committee D-4 on Road and Paving Materials.[4]

Method No. 2

Procedure

6. (*a*) Weigh approximately 2 g. of the sample into a tared conical flask,

[4] *Proceedings*, Am. Soc. Testing Mats., Vol. 37, Part I, p. 395 (1937).

and treat with 100 ml. of c.p. carbon disulfide. Stopper the flask loosely, and shake at intervals until all large particles have been broken down. Then allow the flask to remain undisturbed for 48 hr.

(*b*) Decant the solution into a similar tared flask, taking care to disturb as little of the residue as possible. Treat the residue in the first flask with 100 ml. of c.p. carbon disulfide, shake thoroughly, and allow both flasks to remain undisturbed for 48 hr.

(*c*) Carefully decant the solution from the second flask upon the prepared Gooch crucible, filtering without the use of suction. Then in a similar manner filter the solution from the first flask. Wash the filter with fresh carbon disulfide. Add carbon disulfide to the residue remaining in each flask, shake thoroughly, and allow to settle for 24 hr.

(*d*) Decant the solutions from both flasks through the filter. Again wash the residues remaining in the flasks with carbon disulfide, decanting and filtering the solutions as before. Repeat this treatment until the washings are practically colorless. Maintain the temperature between 20 and 25 C. Dry the crucible and the flasks at 100 to 125 C., and weigh. The total increase in weight over the total original weight is the weight of matter insoluble in carbon disulfide. Evaporate the filtrate containing the bitumen, burn the bituminous residue, and weigh. Add the weight of ash thus obtained to the weight of insoluble matter in the Gooch crucible and conical flasks. The sum of these weights is the total weight of matter insoluble in carbon disulfide.

Calculation and Report

7. (*a*) *Calculation.*—The weight of sample taken calculated to a water-free basis minus the total weight of matter insoluble in carbon disulfide is the weight of bitumen. The percentages of bitumen and of ash shall be calculated on the basis of water-free material.

(*b*) *Report.*—In every case the report shall indicate whether method No. 1 or No. 2 has been employed.

APPROVED AS
AMERICAN STANDARD
THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.12-1943

Standard Method of Test for

PROPORTION OF BITUMEN SOLUBLE IN CARBON TETRACHLORIDE[1]

A.S.T.M. Designation: D 165 - 42

ADOPTED, 1927; REVISED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 165; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the proportion of bitumen soluble in carbon tetrachloride.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Gooch Crucible*, approximately 4.4 cm. in width at the top, tapering to 3.6 cm. at the bottom, with a depth of 2.5 cm.

(*b*) *Asbestos* (amphibole), Gooch grade, acid washed, cut in pieces not exceeding 1 cm. in length, shredded, and shaken up with water.

(*c*) *Flasks.*—Two 125-ml. conical flasks such as Erlenmeyer flasks.

(*d*) *Filtering Flask.*

(*e*) *Filter Tube.*

(*f*) *Section of Rubber Tubing*, to hold the Gooch crucible on the filter tube.

(*g*) *Drying Oven.*

(*h*) *Bunsen Burner.*

(*i*) *Suction Pump.*

(*j*) *Analytical Balance.*

(*k*) *Desiccator.*

Preparation of Sample

3. The sample shall be representative, and if it contains more than 2 per cent of water it shall be dehydrated by distillation in a copper still in accordance with the Standard Method of Test for Water in Creosote (A.S.T.M. Designation: D 370) of the American Society for Testing Materials,[3] and the water-free distillate returned to the residue. If the material is hard and brittle, it may be ground, and dried at a temperature below the temperature of volatilization of the material.

Preparation of Gooch Crucible

4. Insert the filter tube in the stopper of the filtering flask, set the Gooch crucible in the filter tube, and connect the flask to the suction pump. Fill the crucible with some of the suspension of asbestos in water, allow it partly to settle in the crucible, and apply a light

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1923 to 1927, being revised in 1926 and 1927.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

suction to draw off the water, leaving a firm mat of asbestos in the crucible. Add more suspended asbestos and repeat the process until a mat is built up that weighs 0.5 ± 0.1 g. after ignition (Note). Wash the asbestos mat thoroughly with water, dry in the oven, and ignite over a bunsen burner. Cool the crucible in the desiccator, weigh, and replace it in the dry filter tube supported in the clean, dry filtering flask.

NOTE.—In the determination, the asbestos apparently adsorbs irreversibly a small amount of soluble bitumen (usually 1 to 5 mg. per gram of asbestos) which is not removed by subsequent washing with solvent. The weight of asbestos used, therefore, should be kept within the specified limits to ensure reproducible results.

Procedure

5. (*a*) Weigh approximately 2 g. of the sample into a tared conical flask, and add in small portions 100 ml. of c.p. carbon tetrachloride with continued agitation until all lumps disappear and nothing adheres to the bottom of the flask. Then stopper the flask and set aside in subdued light for at least 12 hr.

(*b*) Decant the carbon tetrachloride solution carefully through the asbestos mat in the prepared Gooch crucible, with or without light suction as may be found necessary, retaining as much of the sediment as possible in the conical flask until the solution has drained through the mat. With a small amount of carbon tetrachloride wash down the sides of the flask and transfer the sediment and precipitate from the flask to the asbestos mat. The flask may be scrubbed with a feather if necessary in order to remove all of the precipitate. Wash the contents of the crucible with carbon tetrachloride until the washings are colorless, then apply suction to remove the carbon tetrachloride. Dry the crucible in the oven at 100 to 125 C. for 20 min., cool in the desiccator, and weigh. The increase in weight over the original weight is the weight of matter insoluble in carbon tetrachloride.

(*c*) If insoluble matter adheres to the flask, dry the flask, and weigh. Add the increase in weight over the original weight to the weight of insoluble matter in the Gooch crucible.

(*d*) In case there is any question involving the amount of mineral matter that may have passed through the filter, evaporate the filtrate, and burn the bituminous residue. If a carbonate mineral is present in the filtrate ash, add to the ash a few drops of ammonium carbonate solution, and dry at 100 C., then heat for a few minutes to a dull red heat, and cool in the desiccator. Weigh, and add the weight of ash obtained to the weight of matter insoluble in carbon tetrachloride.

Calculation and Report

6. (*a*) *Calculation.*—The weight of sample taken calculated to a water-free basis minus the total weight of matter insoluble in carbon tetrachloride is the weight of bitumen soluble in carbon tetrachloride. The percentage shall be calculated on the basis of water-free material.

(*b*) *Report.*—The proportion of bitumen soluble in carbon tetrachloride shall be reported on the basis of total bitumen taken as 100, as follows:

$$P = \frac{\text{bitumen soluble in carbon tetrachloride}}{\text{total bitumen}}$$

where:

P = proportion of bitumen soluble in carbon tetrachloride.

HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 52-42

Standard Method of Test for

DISTILLATION OF TAR PRODUCTS SUITABLE FOR ROAD TREATMENT[1]

A.S.T.M. Designation: D 20 – 30

ADOPTED, 1930.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 20; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

This method is presented without any definition of its scope and accuracy since it is believed that it will become applicable to a wider range of materials than indicated by the title. So far the committee has determined its accuracy on one class of materials and further work will be done.

Apparatus

1. The apparatus shall consist of the following:

(*a*) *Flask.*—A side-neck distillation flask, as shown in Fig. 1, having the following dimensions:

Diameter of bulb, outside	86 ± 1.5 mm.
Diameter of neck, inside	22 ± 1.0 mm.
Diameter of tubulature, inside	10 ± 0.5 mm.
Height of flask, outside	131 ± 1.5 mm.
Vertical distance bottom of bulb, outside, to horizontal tangent at tubulature inside	93 ± 1.5 mm.
Length of tubulature	220 ± 5.0 mm.
Angle of tubulature	73 ± 2 deg.
Thickness of tubulature wall	1.0 to 1.5 mm.

(*b*) *Condenser Tube.*—A suitable form of tapered glass condenser tube having the following dimensions:

Outside diameter of small end	12.5 ± 1.5 mm.
Outside diameter of large end	28.5 ± 3.0 mm.
Length	360.0 ± 4.0 mm.
Length of tapered part	100.0 ± 5.0 mm.

(*c*) *Shield.*—A galvanized iron shield, lined with $\frac{1}{8}$-in. asbestos, of the form and dimensions shown in Fig. 2, to protect the flask from air currents and to prevent radiation. The cover (top) may be of transite board made in two parts, or it may be of galvanized iron lined with $\frac{1}{8}$-in. asbestos.

NOTE.—The use of the shield with observation windows (see the Standard Method of Test for Distillation of Cut-Back Asphaltic Products (A.S.T.M. Designation: D 402) of the American Society for Testing Materials[3]) is permissible.

(*d*) *Receivers.*—Tared Erlenmeyer flasks having a capacity of 50 to 100 ml.

(*e*) *Thermometer.*—An A.S.T.M. High Distillation Thermometer, total immersion, graduated in either Centigrade or

[1] Under the standardization procedure of the Society this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to its present adoption as standard, this method was published as tentative from 1911 to 1916, being revised in 1916. It was adopted in 1916, revised in 1918, but withdrawn and replaced by D 20 - 27 T which was published as tentative from 1926 to 1930, being revised in 1927, 1928, and 1930. Editorially revised in 1939 and 1942.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Fahrenheit degrees as specified, having a range of 0 to 400 C. or 30 to 760 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

NOTE.—Under certain test conditions the bulb of the thermometer may be 50 F. (28 C.) above the temperature indicated by the thermometer, and at an indicated temperature of 700 F. (371 C.) the temperature of the bulb is approaching a critical range in the glass. It is therefore not desirable to use this thermometer under such conditions at indicated temperatures above 700 F. (371 C.) without checking the ice point.

If water is present in excess of 2.0 per cent, the bituminous material shall be dehydrated before distillation in accordance with the Standard Method of Test for Water in Creosote (A.S.T.M. Designation: D 370) of the American Society for Testing Materials.[3]

Apparatus Assembly

4. (*a*) The flask shall be supported on a tripod or rings over two sheets of 20-mesh wire gauze, 150 mm. square, as shown in Fig. 3. It shall be connected to the condenser tube by a tight cork joint. The thermometer shall be inserted through a cork in the neck with the top of the bulb level with the lowest point of juncture of the tubulature and neck of the flask.

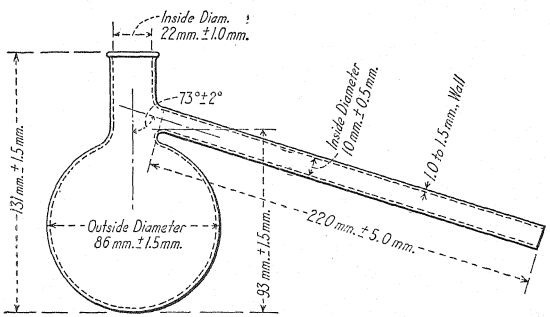

FIG. 1.—Distillation Flask.

Preparation of Sample

2. The sample, as received, shall be thoroughly stirred and agitated, warming, if necessary, to insure a complete mixture before the portion for analysis is removed.

Dehydration of Sample

3. The material may be tested for distillation without dehydration if water is present not to exceed 2.0 per cent.

(*b*) The axis of the bulb of the flask through the center of the neck shall be vertical and the thermometer shall be aligned on this axis.

(*c*) The distance from the neck of the flask to the outlet end of the condenser tube shall be not more than 600 nor less than 500 mm. The burner

should be protected from drafts by a suitable shield or chimney (see Fig. 3).

Procedure

5. (*a*) One hundred grams plus or minus 0.1 g. of the sample shall be weighed into the flask, the apparatus assembled, and heat applied so that the first drop comes over in from 5 to 15 min. The distillation shall be conducted at the rate of between 50 and 70 drops per min. and the distillate collected in weighed receivers. (For weighing the receivers and fractions, a balance accurate to at least 0.05 g. shall be used.) The condenser tube shall be warmed whenever necessary to prevent accumulation of solid distillates. The fraction shall be collected at the temperatures designated by the specifications. The receivers shall be changed when the thermometer indicates the maximum temperature for each fraction. When the maximum specified temperature of the test is indicated by the thermometer, the flame shall be removed and any oil which has condensed in the condenser tube shall be drained into the last fraction.

(*b*) The residue shall be retained in the flask with the cork and thermometer in position until no vapors are visible, and it shall then be weighed. If tests of the residue are required, the flask

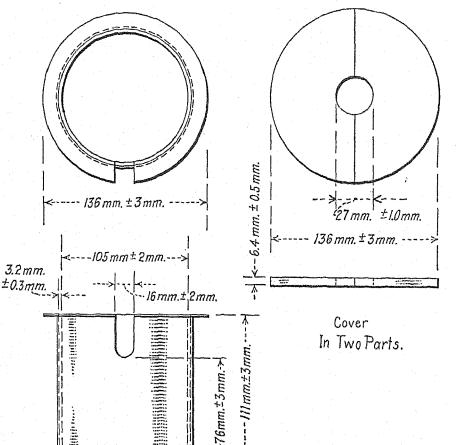

FIG. 2.—Shield.

shall then be inclined so that the residue will flow around the sides, thus collecting any condensed vapors that may be on the sides of the flask, after which the residue shall be poured into a suitable receptacle and covered. If the residue becomes so cool that it cannot be poured readily from the flask, it shall be reheated to a temperature not exceeding 125 C. by holding the bulb of the flask in a suitable bath and not by the application of flame.

(*c*) During the progress of the distillation the thermometer shall remain in its original position. No correction shall be made for the emergent stem of the thermometer.

Report

6. The results of the distillation test shall be reported in percentages by weight of water-free material. The following fractions are usually reported:

Up to 170 C.
170 to 235 C.
235 to 270 C.
270 to 300 C.
Residue.

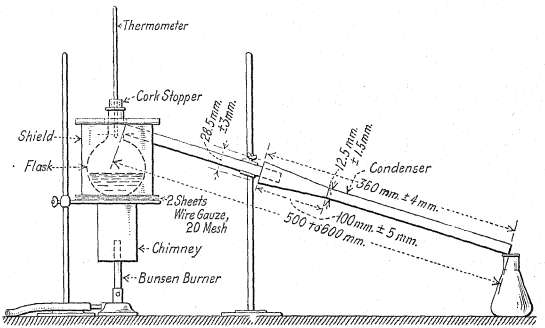

FIG. 3—Distillation Apparatus Assembly.

Standard Method of Test for

DISTILLATION OF CUT-BACK ASPHALTIC PRODUCTS[1]

A.S.T.M. Designation: D 402 - 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 402; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the separation of the volatile and nonvolatile portions of cut-back asphaltic products.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Flask.*—A side neck distillation flask, as shown in Fig. 1, having the following dimensions:

Diameter of bulb, outside.....	86 ± 1.5 mm.
Diameter of neck, inside.....	22 ± 1.0 mm.
Diameter of tubulature, inside.	10 ± 0.5 mm.
Height of flask, outside.....	131 ± 1.5 mm.
Vertical distance bottom of bulb, outside, to horizontal tangent at tubulature, inside.	93 ± 1.5 mm.
Length of tubulature.....	220 ± 5.0 mm.
Angle of tubulature.....	73 ± 2 deg.
Thickness of tubulature wall..	1.0 to 1.5 mm.

(*b*) *Condenser.*—A 250-mm. standard glass-jacketed condenser. The following dimensions are recommended (see Fig. 3):

Length of jacket excluding the necks.....	250 ± 5 mm.
Outside diameter of adapter of condenser tube.....	23 ± 1 mm.
Length of adapter.....	75 ± 5 mm.
Outside diameter of condenser tube proper.....	12.5 ± 0.5 mm.
Over-all length of condenser tube including adapter....	475 ± 25 mm.

(*c*) *Adapter.*—An adapter of the curved design having a heavy wall (1 mm.) and reinforced top glass, with an angle of approximately 105 deg., and with a diameter at the large end of approximately 18 mm. The outlet end shall be ground to an angle of 45 ± 5 deg. with the inside vertical.

(*d*) *Shield.*—A galvanized iron shield, lined with $\frac{1}{8}$-in. asbestos, fitted with transparent covered windows, of the form and dimensions shown in Fig. 2, used to protect the flask from air currents and to prevent radiation. The cover (top) may be of transite board made in two parts, or it may be of galvanized iron lined with $\frac{1}{8}$-in. asbestos.

(*e*) *Receivers.*—Graduated cylinders, of uniform diameter, with a pressed or molded base and a lipped top. The over-all height shall be not less than

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1934 to 1936, being revised in 1936. Editorially revised and rearranged in 1939.

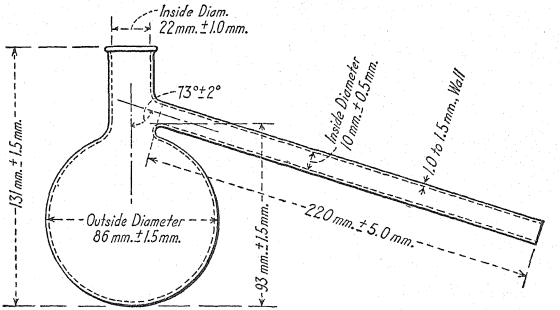

FIG. 1.—Distillation Flask.

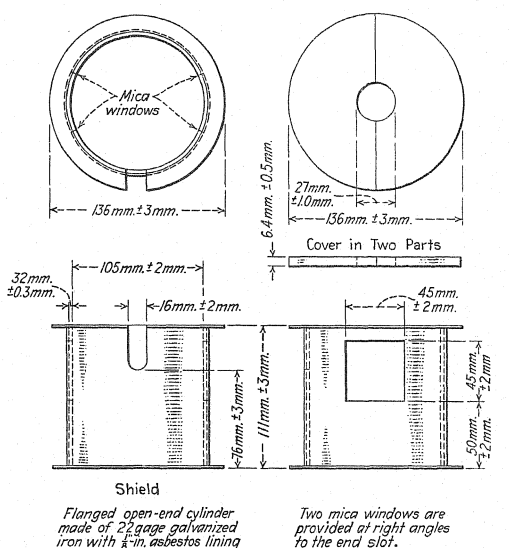

FIG. 2.—Shield.

24.8 cm. (9¾ in.) nor more than 26.0 cm. (10¼ in.). The cylinder shall be graduated in single milliliters to contain 100 ml., and the graduated portion shall be not less than 17.78 cm. (7 in.) nor more than 20.32 cm. (8 in.) in length. Each fifth graduation shall be distinguished by a longer line, and the graduations shall be numbered from the bottom up at intervals of 10 ml. The graduations shall not be in error by more than 1 ml. at any point on the scale.

(*f*) *Thermometer.*—An A.S.T.M. High Distillation Thermometer, total immersion, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of 0 to 400 C. or 30 to 760 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

Preparation of Sample

3. The sample, as received, shall be thoroughly stirred and agitated, warming, if necessary, to insure a complete mixture before the portion for analysis is removed.

Dehydration of Sample

4. The material may be tested for distillation without dehydration if water is present not to exceed 2.0 per cent. If water is present in excess of 2.0 per cent, the bituminous material shall be dehydrated before distillation in accordance with the Standard Method of Test for Water in Creosote (A.S.T.M. Designation: D 370) of the American Society for Testing Materials.[3]

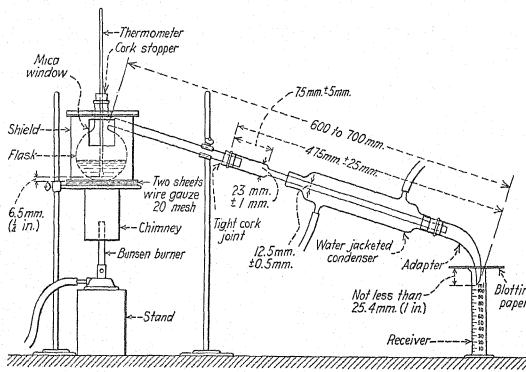

FIG. 3.—Distillation Apparatus Assembly.

Apparatus Assembly

5. (*a*) The flask shall be supported on a tripod or ring over two sheets of 20-mesh wire gauze, 150 mm. square as shown in Fig. 3. It shall be connected to the condenser tube by a tight cork joint. The thermometer shall be inserted through a cork in the neck with the bottom of the bulb 6.5 mm. (¼ in.) from the bottom of the flask.

(*b*) The axis of the bulb of the flask through the center of the neck shall be vertical and the thermometer shall be aligned on this axis.

(*c*) The distance from the neck of the

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

flask to the outlet end of the adapter shall be not more than 700 nor less than 600 mm. The burner should be protected from drafts by a suitable shield or chimney (see Fig. 3).

(*d*) The adapter shall be adjusted over the end of the condenser tube so as to conduct the distillate into the receiver, and the top of the receiver shall be covered closely during the distillation with a piece of blotting paper or its equivalent, which shall be cut so as to fit the adapter tightly. The adapter shall extend into the receiver at least 2.54 cm. (1 in.) but not below the 100-ml. mark. Unless the laboratory air temperature is between 12.8 and 18.3 C. (55 and 65 F.) the receiver shall be immersed up to the 100-ml. mark in a transparent bath maintained between these temperatures.

(*e*) The condenser tube shall be clean and dry.

Procedure

6. (*a*) Two hundred milliliters[4] (calculated from the specific gravity of the material at 15.5 C. (60 F.)) of the sample shall be weighed into the flask, the apparatus assembled and heat applied so that the first drop comes over in from 5 to 15 min. The distillation shall be conducted at the rate of between 50 and 70 drops per min., except that near the end of the distillation the heat input shall not be so rapid as to result in a temperature in excess of 360 C. (680 F.) after the flame has been removed. Should the sample foam, the distillation rate will have to be reduced, but the normal rate shall be resumed as soon as possible. If excess foaming persists, the distillation may be more easily controlled by applying the flame near the edge of the bulb instead of at the center of same. The distillate shall be collected in the specified receivers, and the volume of distillate at all specified temperatures recorded. The volume of any separated water shall also be recorded. When the maximum specified temperature of the test is indicated by the thermometer, the flame shall be removed and the residue poured *immediately* into a 6-oz. tin box, 70 mm. ($2\frac{3}{4}$ in.) in diameter and 45 mm. ($1\frac{3}{4}$ in.) in depth (Note), placed on its cover to prevent too rapid cooling at the bottom. Any oil which may remain in the condenser tube shall be drained into the last receiver.

NOTE.—Containers known in the drug trade as seamless "ointment boxes" may be obtained in dimensions conforming to the above requirements.

(*b*) As soon as no further vaporization is apparent, the residue shall be stirred to insure uniformity, and then poured into the necessary apparatus for the required tests.

(*c*) During the progress of the distillation the thermometer shall remain in its original position. No correction shall be made for the emergent stem of the thermometer. Temperatures to be observed in the distillation test shall be corrected for the effect of the altitude of the laboratory in which the test is made in accordance with the Standard Method of Test for Distillation of Gasoline, Naphtha, Kerosine, and Similar Petroleum Products (A.S.T.M. Designation: D 86) of the American Society for Testing Materials.[3]

Report

7. The results of the distillation test shall be reported in percentage by volume of water-free material. The following fractions are usually reported:

Up to 225 C. (437 F.),
Up to 316 C. (600 F.), and
Up to 360 C. (680 F.).

Additional fractions may be specified, such as:

Up to 160 C. (320 F.),
Up to 175 C. (347 F.), and
Up to 190 C. (374 F.).

[4] In the case of persistently foaming material, one half of this amount may be employed.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.11-1944
AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 51-44

Standard Method of Test for
DUCTILITY OF BITUMINOUS MATERIALS[1]

A.S.T.M. Designation: D 113 - 44

ADOPTED, 1935; REVISED, 1939, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 113; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. The ductility of a bituminous material is measured by the distance to which it will elongate before breaking when two ends of a briquet specimen of the material, of the form described in Section 2, are pulled apart at a specified speed and at a specified temperature. Unless otherwise specified, the test shall be made at a temperature of 25 ± 0.5 C. (77 ± 0.9 F.) and with a speed of 5 cm. per min. plus or minus 5.0 per cent. When a low-temperature ductility test is desired the test shall be made at a temperature of 4 C. (39.2 F.) and at a rate of pull of 1 cm. per min.

Apparatus

2. (*a*) *Mold.*—The mold shall be similar in design to that shown in Fig. 1. Dimensions shown in Fig. 1 shall be as given with the permissible variations indicated. The mold shall be made of brass, the ends *b* and *b'* being known as clips, and the parts *a* and *a'* as sides of the mold. The dimensions of the mold shall be such that, when properly assembled, it will form a briquet specimen having the following dimensions:

Total length	7.45 to 7.55 cm.
Distance between clips	2.97 to 3.03 cm.
Width at mouth of clip	1.98 to 2.02 cm.
Width at minimum cross-section (halfway between clips)	0.99 to 1.01 cm.
Thickness throughout	0.99 to 1.01 cm.

(*b*) *Water Bath.*—The water bath shall be maintained at the specified test temperature, varying not more than 0.1 C. (0.18 F.) from this temperature. The volume of water shall be not less than 10 liters, and the specimen shall be immersed to a depth of not less than 10 cm. and shall be supported on a perforated shelf not less than 5 cm. from the bottom of the bath.

(*c*) *Testing Machine.*—For pulling the briquet of bituminous material apart, any apparatus may be used which is so constructed that the specimen will be continuously immersed in water as specified in Section 3(*c*), while the two clips are pulled apart at a uniform speed, as specified, without undue vibration.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1921 to 1935, being revised in 1922, 1926, 1932, and 1935.

Procedure

3. (*a*) *Molding Test Specimen.*—The bituminous material to be tested shall be completely melted until thoroughly fluid by heating it in an oil bath maintained at the minimum temperature needed to properly liquefy the sample (Note). It shall then be strained through a No. 50 (297-micron) sieve conforming to the requirements prescribed in the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials[3] and, after a thorough stirring, poured into the mold. The mold shall be assembled on a brass plate and, so as to prevent the material under test from sticking, the surface of the plate and interior surfaces of the sides *a* and *a'*, Fig. 1, of the mold shall be

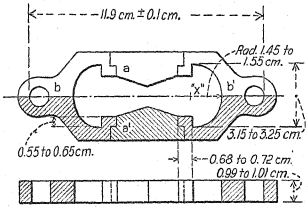

FIG. 1.—Mold for Ductility Test Specimens.

NOTE.—The opening in the end of each clip, as indicated by "x," shall be half an ellipse having a transverse axis of 3.2 ±0.05 cm. and half of the longitudinal axis shall be 1.45 to 1.55 cm.

thoroughly amalgamated. The plate upon which the mold is placed shall be perfectly flat and level so that the bottom surface of the mold will touch it throughout. In filling the mold, care shall be taken not to disarrange the parts and thus distort the briquet. In filling, the material shall be poured in a thin stream back and forth from end to end of the mold until it is more than level full. It shall be left to cool to room temperature for a period of from 30 to 40 min. and then placed in the water bath maintained at the specified temperature of test for 30 min., after which the excess bitumen shall be cut off by means of a hot straight-edged putty knife or spatula so that the mold shall be just level full.

NOTE.—When paving asphalt cements are being tested, the oil bath shall be maintained at a temperature of from 150 to 160 C. (302 to 320 F.).

(*b*) *Keeping Specimen at Standard Temperature.*—The brass plate and mold, with briquet specimen, shall then be placed in the water bath and kept at the specified temperature for a period of from 85 to 95 min., when the briquet shall be removed from the plate, the side pieces detached, and the briquet immediately tested.

(*c*) *Testing.*—The rings at each end of the clips shall be attached to the pins or hooks in the testing machine and the two clips pulled apart at a uniform speed as specified until the briquet ruptures. A variation of plus or minus 5 per cent from the speed specified will be permissible. The distance through which the clips have been pulled to produce rupture shall then be measured in centimeters. While the test is being made, the water in the tank of the testing machine shall cover the specimen both above and below it by at least 2.5 cm. and shall be kept continuously at the temperature specified within plus or minus 0.5 C. (0.9 F.).

Report

4. (*a*) A normal test is one in which the material between the two clips pulls out to a point or thread until rupture occurs at the point where the thread has practically no cross-sectional area. The average of three normal tests shall be taken and reported as the ductility of the sample.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) If the bituminous material comes in contact with the surface of the water or the bottom of the bath, the test shall not be considered normal. The specific gravity of the bath shall be adjusted by the addition of either methyl alcohol or sodium chloride so that the bituminous material does not either come to the surface of the water, or touch the bottom of the bath at any time during the test.

(*c*) If a normal test is not obtainable on three successive tests, the ductility shall be reported as being unobtainable under the conditions of the test.

Standard Methods of

TESTING EMULSIFIED ASPHALTS[1]

A.S.T.M. Designation: D 244 - 42

ADOPTED, 1939; REVISED, 1940, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 244; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods are intended for the examination of asphalt emulsions composed, principally, of a semisolid or liquid asphaltic base, water, and an emulsifying agent.

VISCOSITY

2. The viscosity of emulsified asphalt shall be determined by means of the Saybolt Furol viscosimeter.

Apparatus

3. The apparatus shall consist of the following:

(*a*) *Viscosimeter.*—A Saybolt Furol viscosimeter conforming to the requirements specified in the Standard Method of Test for Viscosity by Means of the Saybolt Viscosimeter (A.S.T.M. Designation: D 88) of the American Society for Testing Materials.[3]

(*b*) *Strainer.*—A 20-mesh strainer of iron wire cloth, framed or unframed.

Procedure

4. (*a*) The viscosity determination shall be made at 77 F. (25 C.) and shall be expressed in seconds, Saybolt Furol, being the time in seconds for the delivery of 60 ml. of emulsion.

(*b*) While the Saybolt Furol viscosimeter is not used for petroleum products and lubricants when the time of flow is less than 25 sec., this instrument is satisfactory for testing emulsified asphalt when the time of flow is not less than 20 sec.

(*c*) *Preparation of Sample.*—The sample shall be stirred thoroughly without incorporating bubbles in it and then poured into a 4-oz. bottle. The bottle shall then be placed in the water bath at 77 F. (25 C.) for 30 min. and the sample then mixed in the bottle by inverting several times, slowly enough to prevent bubble formation. The sample shall then be poured into the vis-

[1] Under the standardization procedure of the Society, these methods are under the joint jurisdiction of A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1926 to 1939, being revised in 1928, 1933, 1934, 1935, 1936, and 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

cosity tube through a 20-mesh strainer, allowing a small portion to flow through the outlet tube to waste. The cork shall then be placed in position, the tube filled and without again stirring the sample the viscosity shall be determined as described in the Standard Method of Test for Viscosity by Means of the Saybolt Viscosimeter (A.S.T.M. Designation: D 88) of the American Society for Testing Materials.[3]

ring burners are required, one approximately 6 in. in inside diameter with the holes bored on the inside periphery, and one approximately 2 in. in diameter with the holes bored on top.

(*b*) *Connecting Apparatus.*—A connecting tube, tin shield, condenser trough, condenser tube and graduated cylinder, as shown in Fig. 1.

(*c*) *Thermometer.*—An A.S.T.M. Low-Distillation Thermometer, graduated in either Fahrenheit or Centigrade degrees

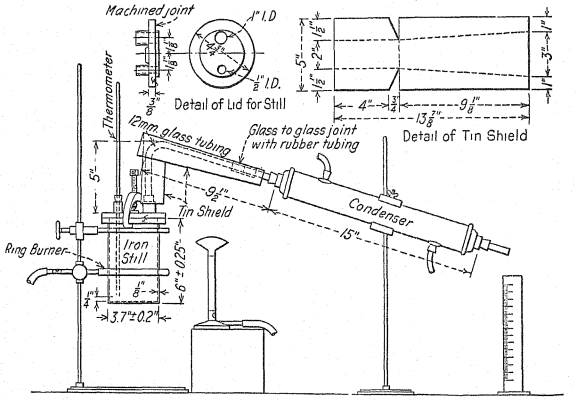

FIG. 1.—Apparatus Assembly for Distillation Test of Emulsified Asphalts.

DISTILLATION

Apparatus

5. The apparatus shall consist of the following:

(*a*) *Iron Still.*—The iron still shall be approximately 6 by 3½ in. in inside diameter with adjustable ring burner having holes on the inner periphery to fit around the outside of the still.

NOTE.—A modification of this still is shown in Fig. 2; either the still shown in Fig. 1 or that shown in Fig. 2 may be used interchangeably. It consists of the regular still with an expansion chamber superimposed thereon. Two additional

as specified, having a range of 30 to 580 F. or 0 to 300 C. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

NOTE.—The details of the assembly of apparatus for the distillation test are illustrated in Fig. 1.

Procedure

6. (*a*) Exactly 200 g. of a well-mixed and representative sample of the emul-

sion shall be placed in the previously weighed iron still (including lid, clamp, thermometer, and gasket, if gasket is used).

(*b*) A gasket of oiled paper may be used between the still and its cover or the joint ground to a tight fit. The cover shall be clamped securely on the still.

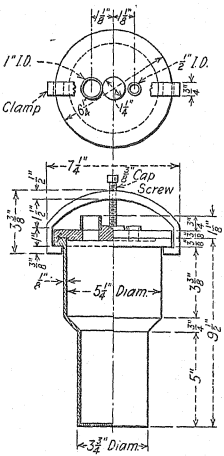

FIG. 2.—Iron Still for Use with Badly Foaming Emulsions.

(*c*) The thermometer shall be inserted through the small hole in the cover, using a cork stopper, so that the end of the bulb is ½ in. from the bottom of the still.

(*d*) The ring burner shall be placed around the still and the heat applied by this means to the top of the still. Just enough heat from a bunsen burner shall also be applied to the connecting tube to prevent condensation of water in this tube.

(*e*) After practically all the condensate has been removed from the still and the temperature of the residue has reached 250 F. (121 C.), the position of the heat from the ring burner shall be lowered to midway of the still and held there until the thermometer reaches 349 F. (176 C.). The burner shall then be rapidly lowered to within ¼ in. of the bottom of the still and the temperature increased to and maintained at 500 F. (260 C.) for 15 min. This latter period of heating is necessary to insure a smooth homogeneous residue in the still.

(*f*) At the expiration of the heating period at the maximum temperature, the still and accessories shall again be weighed as described in Paragraph (*a*) and the percentage residue calculated and reported. The cover shall then be removed from the still and suitable portions of the residue shall be poured immediately through a 297-micron (No. 50) sieve into suitable molds and containers for making the required tests. The residue in the molds and containers shall be permitted to cool, uncovered, to laboratory room temperature and thereafter tested as described in Sections 36 to 40, inclusive.

NOTE.—When it appears impossible to distill an emulsified asphalt in the still described in Section 5 (*a*) due to excessive foaming of the emulsion, then the modified still shown in Fig. 2 should be substituted for the still shown in Fig. 1 and the following procedure followed: Place the 6-in. burner around the larger diameter of the still near its top. This serves as a support. Place the 4-in. burner immediately beneath the flare and the 2-in. burner not less than 2 in. below the bottom. Distillation is started with only the 2-in. burner lighted. Practically all of the distillate should be over in about 45 min. When the distillation apparently stops, light the two larger ring burners and adjust to a low flame. Distillation resumes and when it stops again increase the heat by adjusting the flame of the 2-in. burner. When the temperature can be read upon the thermometer, increase the rate of heating by raising the flame on both the 2 and 4-in. burners and bring the temperature to 500 F. (260 C.).

If any evidence is noted of the emulsion beginning to foam over in the delivery tube, re-

move the 2-in. burner quickly and raise a pan of water so as to immerse the still bottom to a depth of about 2 in. for a moment which will check the foaming. Upon resumption of heating, watch delivery tube carefully and repeat treatment if necessary.

When the residue has reached and remained at 500 F. (260 C.) for 15 min., proceed as described in Section 6 for the regular still. While the distillation should be completed in not less than 1 hr. nor more than 1½ hr. from the first application of heat to the still, the maximum stated is not mandatory, as a longer time may be required in some cases to avoid foaming of the emulsion into the condenser.

If the residue in the still prior to pouring the ductility and penetration specimens appears granular or heterogeneous in any way, stir with a spatula until the material runs from the spatula in strings instead of drops, and then pour.

DETERMINATION OF WATER

Scope

7. This method of test determines water existing in a sample of bituminous emulsion by distilling the sample with a volatile solvent.

Apparatus

8. (a) The apparatus shall consist of a metal still or glass flask, heated by suitable means and provided with a reflux condenser discharging into a trap connected to the still or flask. The trap serves to collect and measure the condensed water and to return the solvent to the still. The type of distilling apparatus used is not an essential feature of this method.

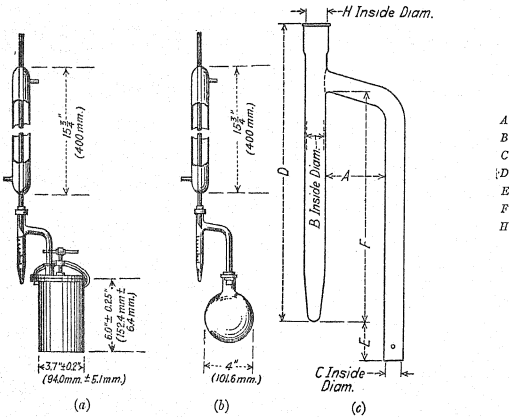

FIG. 3.—Apparatus for Determining Water.

(b) *Metal Still.*—The metal still, Fig. 3 (*a*), shall be a vertical cylindrical vessel, preferably of copper, having a faced flange at the top to which the head is tightly attached by means of a clamp. The head shall be of metal, preferably of brass or copper, and be provided with a tubulation 1 in. in inside diameter.

(c) *Glass Still.*—The glass flask,

Fig. 3 (*b*), shall be of the short neck, round-bottom type, made of well-annealed glass, having an approximate capacity of 500 ml.

(*d*) *Heat Source.*—The burner used with the metal still shall be a ring gas burner 100 mm. (4 in.) in inside diameter. With the glass flask, an ordinary gas burner or electric heater may be used as the source of heat.

(*e*) *Condenser.*—The condenser shall be of the water-cooled, reflux, glass-tube type, having a condenser jacket not less than 400 mm. (15¾ in.) in length with an inner tube 9.5 to 12.7 mm. (⅜ to ½ in.) in outside diameter. The end of the condenser to be inserted in the trap shall be ground off at an angle of 30 ± 5 deg. from the vertical axis of the condenser.

(*f*) *Trap.*—The trap shall be made of well-annealed glass, constructed in accordance with Fig. 3 (*c*), and shall be graduated from 0 to 2 ml. in 0.1-ml. divisions, and from 2 to 25 ml. in 0.2-ml. divisions. The tolerance of the graduations between 0 and 2 ml. shall be plus or minus 0.05 ml. and between 2 and 25 ml. shall be plus or minus 0.1 ml.

Solvent

9. The solvent used when testing bituminous emulsions shall be a coal-tar naphtha or a light oil and shall conform to the following distillation requirements, determined in accordance with the Standard Method of Test for Distillation of Gasoline, Naphtha, Kerosine, and Similar Petroleum Products (A.S.T.M. Designation: D 86) of the American Society for Testing Materials:[3]

> 98 per cent shall distill between 248 F. (120 C.) and 482 F. (250 C.).

Sample

10. The sample shall be thoroughly representative of the material to be tested and the portion of the sample used for the test shall be thoroughly representative of the sample itself. Deviation from this requirement shall not be permitted.

NOTE.—The difficulties in obtaining proper representative samples for this determination are unusually great so that the importance of sampling cannot be too strongly emphasized.

Procedure

11. (*a*) When the material to be tested contains less than 25 per cent of water, exactly a 100-g. sample shall be placed in the still or flask. When the material contains more than 25 per cent of water, the sample shall be 50 g. The sample to be tested shall be thoroughly mixed with an equal volume of solvent by swirling, proper care being taken to avoid any loss of material.

(*b*) The connections between the still or flask, trap and condenser shall be made by means of tight-fitting corks as shown in Fig. 3 (*a*) and (*b*). The end of the condenser inserted in the trap shall be adjusted to that position which will allow the end to be submerged to a depth of not more than 1 mm. (0.04 in.) below the surface of the liquid in the trap after distillation conditions have been established. When the metal still is used, a heavy paper gasket moistened with the solvent shall be inserted between the lid and flange before attaching the clamp. A loose cotton plug shall be inserted in the top of the condenser tube to prevent condensation of atmospheric moisture in the condenser tube.

(*c*) Heat shall then be applied and so regulated that the condensed distillate falls from the end of the condenser at the rate of from 2 to 5 drops per sec. The ring burner used with the metal still shall be placed about 3 in. above the bottom of the still at the beginning of the distillation and gradually lowered as the distillation proceeds.

(*d*) The distillation shall be continued at the specified rate until no water is visible on any part of the apparatus except at the bottom of the trap. This operation usually requires less than 1 hr. A persistent ring of condensed water in the condenser tube shall be removed by increasing the rate of distillation for a few minutes.

Calculation and Reporting of Results

12. The volume of condensed water measured in the trap at room temperature multiplied by 100 and divided by the weight of sample used, shall be the percentage of water and shall be reported as "....per cent water by weight, A.S.T.M. Method D 244."

Reproducibility of Results

13. The accuracy to be expected with this method is that duplicate determinations of water should not differ from each other by more than one division on the trap.

SETTLEMENT

Apparatus

14. The apparatus shall consist of the following:

(*a*) *Cylinders.*—Two glass cylinders of 500-ml. capacity with pressed or molded glass base and cork or glass stoppers. The outside diameter shall be 5.0 ± 0.5 cm. and the cylinders shall be graduated at each 5-ml. interval to the 500-ml. mark.

(*b*) *Glass Pipette.*—A siphon, glass tube pipette, 60-ml. capacity, form optional.

Procedure

15. (*a*) A 500-ml. sample, representative of the emulsion, shall be placed in each of two glass cylinders. The cylinder shall be stoppered airtight and stood aside unmolested, at laboratory air temperature for 5 days. After standing for this 5-day period, approximately the first 55 ml. of emulsion shall be removed by means of the pipette or siphon from the top of each cylinder without disturbing the balance of their contents. Exactly 50 g. of each of the two samples, after each has been thoroughly mixed separately, shall be weighed into separate 600-ml. low-form glass beakers and the asphaltic residue determined by evaporation at 325 F. (163 C.) for 3 hr. in the apparatus described in the Tentative Method of Test for Loss on Heating of Oil and Asphaltic Compounds (A.S.T.M. Designation: D 6) of the American Society for Testing Materials.[3]

(*b*) After removal of the first sample, approximately the next 390 ml. shall be siphoned off from each of the cylinders. The residue remaining in the cylinders shall be mixed thoroughly and exactly 50 g. shall be weighed out from each of them and the amount of asphaltic residue (all sediment, if any, included) shall be determined by evaporation as described in Paragraph (*a*) for the two top samples.

(*c*) The numerical difference between the average percentage of asphaltic residue from the two top samples and the average percentage found in the two bottom samples shall be recorded.

DEMULSIBILITY

Apparatus and Reagents

16. The apparatus and reagents shall consist of the following:

(*a*) *Wire Cloth.*—Three pieces of 1410-micron (No. 14) iron wire cloth approximately 5 in. square, unframed, having wire diameters and openings which conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

(*b*) *Beakers.*—Three metal beakers of 600-ml. capacity each.

(*c*) *Rods.*—Three metal rods, rounded ends, approximately $\frac{5}{16}$ in. in diameter.

(*d*) *Burette.*—A 50-ml. glass burette graduated in 0.1 ml.

(*e*) *Calcium Chloride Solution (0.02 N).*

(*f*) *Calcium Chloride Solution (0.10 N).*

Procedure

17. (*a*) The percentage of residue shall be determined by distillation as described in Section 6.

(*b*) The weight of each assembly of beaker, rod, and wire cloth shall be recorded.

(*c*) Exactly 100 g. of the emulsified asphalt shall be weighed into each of three 600-ml. tared beakers. Over a period of approximately 2 min., 35 ml. of 0.02 *N* $CaCl_2$ solution (if quick-setting emulsion is being tested) or 50 ml. of 0.10 *N* $CaCl_2$ solution (if mixing type emulsion is being tested) shall be added to each beaker from a burette. While adding the solution of $CaCl_2$, the contents of the beaker shall be stirred continuously and vigorously, kneading lumps against the sides of the beaker to insure thorough mixing of the reagent with the emulsion. This operation shall be performed after bringing the weighed sample of emulsion and the reagent to the standard temperature of 77 ± 1.0 F. (25 ± 0.5 C.).

(*d*) One of the wire cloths shall be fitted over a beaker or other suitable vessel and the mixture of emulsion and reagent poured through the wire cloth. The beaker, containing the sample and metal rod, shall be rinsed with distilled water. All lumps shall be kneaded and broken up and the washing of the beaker, rod, and wire cloth shall be continued until there is no longer any appreciable color imparted to the wash water. After washing as directed, the beaker, rod, and wire cloth used in each individual test shall be placed in a drying oven and dried at 325 F. (163 C.) to constant weight.

Calculation

18. The total weight thus obtained less the total tare weight of the beaker, rod and wire cloth shall be the weight of the residue by the demulsibility test. The ratio of the average weight in grams from three tests of each individual sample of emulsified asphalt, *A*, to the weight in grams of residue per 100 g. of emulsion, *B*, obtained in the test for residue by distillation described in Section 6 multiplied by 100, shall be recorded as the percentage of demulsibility of the sample tested:

$$\text{Percentage demulsibility} = \frac{A}{B} \times 100$$

SIEVE TEST

Apparatus and Reagents

19. The apparatus and reagents shall consist of the following:

(*a*) *Sieve.*—A sieve having a 3-in. frame conforming to Section 4 (*a*) and (*b*) of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[3] and having 840-micron (No. 20) wire sieve cloth conforming to Section 3 of these specifications.

(*b*) *Pan.*—A tin box cover or shallow metal pan of appropriate size to fit over the bottom of the standard sieve.

(*c*) *Sodium Oleate Solution (2 per cent).*—Prepare a 2 per cent solution of pure sodium oleate in distilled water.

Procedure

20. The weight of the sieve and pan shall be recorded and the wire cloth of the No. 20 sieve shall then be wet with the sodium oleate solution (2 per cent). Exactly 1000 g. of the emulsified asphalt

shall then be weighed and poured through the wire sieve, the container and the residue on the sieve being washed thoroughly with the sodium oleate solution until the washings run clear. The pan shall then be placed under the sieve and heated for 2 hr. in a drying oven whose interior temperature is 220 F. (105 C.), then cooled in a desiccator, and weighed.

Calculation

21. The total weight of the sieve, pan, and residue in grams less the combined tare weight of the sieve and pan, is the weight of the residue by the sieve test. The percentage of residue retained on the sieve shall be calculated from this weight.

MISCIBILITY WITH WATER

NOTE.—This test is not applicable to the so-called quick-setting type of emulsions.

Procedure

22. To about 50 ml. of the emulsion shall be gradually added about 150 ml. of distilled water, stirring the mixture while adding the water. The temperature is not important but should be between 21 and 25 C. (70 and 77 F.). The mixture shall be allowed to stand for 2 hr. and then examined for any appreciable coagulation of the asphalt content of the emulsion.

MODIFIED MISCIBILITY WITH WATER

Scope

23. This method of test covers the procedure for determining the miscibility with water of medium-setting and slow-setting types of asphalt emulsions. This test is not applicable to the quick-setting type of asphalt emulsions.

Apparatus

24. The apparatus shall consist of the following:

(*a*) *Graduate.*—A 50-ml. graduated cylinder.

(*b*) *Beaker.*—A 400-ml. Griffin low-form glass beaker.

(*c*) *Glass Tubes.*—Three glass tubes, 7 mm. in outside diameter, 5 mm. in inside diameter, and 15 cm. in length, fitted with suitably bored No. 8 corks, adjusted as described in Section 25.

(*d*) *Supporting Strip.*—A strip of metal or wood, approximately 15 cm. in length, 2.5 cm. in width, and 0.5 cm. in thickness, with a hole 10 mm. in diameter in the center.

(*e*) *Crucibles.*—Three 15 or 25-ml. porcelain crucibles, or three 30-ml. beakers of heat-resistant glass.[4]

(*f*) *Oven.*—A constant temperature oven as described in the Tentative Method of Test for Loss on Heating of Oil and Asphaltic Compounds (A.S.T.M. Designation: D 6) of the American Society for Testing Materials.[3]

(*g*) *Balance.*—An analytical balance accurate to 0.1 mg.

Assembly of Apparatus

25. Adjust the position of the corks on the glass tubes by measuring 200 ml. of distilled water at 20 to 25 C. into the 400-ml. beaker, placing the supporting strip across the top of the beaker, inserting a tube through the hole, and adjusting the position of the cork so that when the tube is supported by the cork resting on the supporting strip, the lower end of the tube is immersed in the water to a depth of 1 cm. below the surface. In the same manner, adjust the second and third tubes so that the depth of immersion is 2.5 and 4.6 cm., respectively.

[4] Pyrex glass is very satisfactory for this purpose.

NOTE.—Due to slight differences in height and diameter of 400-ml. beakers as obtained commercially, it may be necessary to readjust the tubes when used in different beakers. In any event, the third or bottom tube shall project into the emulsion so that the tip is within 1 to 1.5 mm. of the bottom of the beaker.

Procedure

26. (*a*) Measure 50 ml. of the emulsion at a temperature of 20 to 25 C. into the graduated cylinder and transfer to the 400-ml. beaker. Wash the graduate with three 50-ml. portions of distilled water at 20 to 25 C. and add the washings to the beaker, bringing the final volume to 200 ml. Stir the emulsion and water with a glass rod until uniformly mixed, cover the beaker with a watch glass, and allow the mixture to stand undisturbed for 2 hr.

(*b*) Weigh the three crucibles or 30-ml. beakers, and a watch glass for each, to the nearest 0.1 mg. After the diluted emulsion has stood for 2 hrs., remove the watch glass and place the supporting strip across the top of the 400-ml. beaker. Take a sample of approximately 1 g. from the top layer and transfer to one of the crucibles or beakers, using the first or 1-cm. depth tube as a pipette. Close the top of the tube with the finger, insert the tube to the proper depth, remove the finger while the emulsion rises in the tube, and then replace the finger on top of the tube so that when the tube is removed its contents of emulsion will be pipetted from the beaker. After removal, wipe off the adhering liquid on the outside of the tube with filter paper before transferring the sample to the crucible. In like manner, take samples from the middle and bottom of the diluted emulsion, using the second and third tubes, respectively. Weigh the crucibles with their accompanying samples of emulsion, and determine the weight of each of the three samples by difference. Cover the crucibles with watch glasses to retard evaporation.

(*c*) Remove the watch glasses from the crucibles and place the samples in the oven at 163 C. for 2 hr., then remove, cool, and weigh.

Calculations and Report

27. Calculate the percentage of asphalt residue in the top, middle, and bottom levels. Report the maximum numerical difference in percentage of asphalt content between any two of the three levels.

CEMENT MIXING

Scope

28. This method of test is intended for determining the amount of coagulation when portland cement is mixed with the slow-setting type of asphalt emulsions for fine aggregate mixes. This test is not applicable when 2 per cent or more coagulation is anticipated.

Apparatus

29. The apparatus shall consist of the following:

(*a*) *Sieves.*—A 177-micron (No. 80) sieve and a 1410-micron (No. 14) sieve, made of iron wire cloth having wire diameters and openings conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

(*b*) *Dish.*—A round-bottom iron dish or a kitchen saucepan of approximately 500-ml. capacity.

(*c*) *Stirring Rod.*—A steel rod with rounded ends, approximately $\frac{1}{2}$ in. in diameter.

(*d*) *Graduate.*—A 100-ml. graduated cylinder.

Cement

30. The high-early-strength portland cement used in the test shall conform to

the requirements for type III of the Standard Specifications for Portland Cement (A.S.T.M. Designation: C 150) of the American Society for Testing Materials,[2] and shall have a minimum specific surface area of 1900 sq. cm. per gram.

Procedure

31. (*a*) Dilute the emulsion to be tested with distilled water to a residue of 55 per cent as determined by either distillation, or evaporation for 3 hr. at 163 C.

(*b*) Sieve a portion of the cement through the 177-micron (No. 80) sieve. Weigh 50 g. of the cement passing the 177-micron sieve into the iron dish.

(*c*) Add 100 ml. of the diluted emulsion to the cement in the dish and stir the mixture at once with the steel rod, using a circular motion, making 60 complete revolutions during 1 min. Immediately at the end of the 1-min. mixing period, add 150 ml. of distilled water and continue the stirring for 3 min. The ingredients and apparatus shall be maintained at a temperature of approximately 25 C. during the mixing period.

(*d*) Pour the mixture through the tared 1410-micron (No. 14) iron sieve, of approximately 3 in. diameter and rinse by pouring distilled water from a receptacle held at a height of approximately 6 in. Place the sieve in a tared shallow pan, heat at 163 C. in an oven until dry, and weigh.

Report

32. Report the weight in grams of the material retained on the sieve and in the pan as the percentage of the emulsion broken.

COATING TEST

NOTE.—This test is applicable only for emulsions containing a base of asphalt of semisolid consistency. It is not applicable to the so-called quick-setting type of emulsions.

Apparatus and Material

33. The apparatus and material required shall consist of the following:

(*a*) *Screens.*—Standard $\frac{3}{4}$-in. and $\frac{1}{4}$-in. round-hole screens conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

(*b*) *Spatula.*—A steel spatula or its equivalent, blade approximately 8 in. in length.

(*c*) *Dish.*—A round-bottom, iron dish or a kitchen saucepan, approximately 1-qt. capacity.

(*d*) *Stone.*—A supply of reference stone (hard limestone, trap rock, or other type) which has been washed with water and dried before using. The grading of this stone shall be such that it will all pass through a standard $\frac{3}{4}$-in. screen and not more than 5 per cent will pass through a $\frac{1}{4}$-in. screen.

NOTE.—Each laboratory shall select its own reference stone supply, the source of which is not apt to change. This is to obviate rapid changes in the character of reference stone used in any one laboratory.

Procedure

34. (*a*) Exactly 465 g. of the washed and dried graded stone, shall be weighed and placed in the metal pan.

(*b*) A 35-g. sample of the emulsion shall then be added to the stone in the pan and mixed vigorously with the spatula for 3 min.

(*c*) Record whether or not there is appreciable separation of the asphaltic base from the water of the emulsion and whether or not the stone is uniformly and thoroughly coated with the emulsion.

FREEZING TEST

Procedure

35. (*a*) Approximately 400 g. of the emulsion shall be placed in a clean metal container, such as a 1-pt. press-top tin.

(*b*) The emulsion in the closed container shall be exposed to a temperature of 0 F. (−17.8 C.) for twelve consecutive hours.

(*c*) At the expiration of the freezing period, the emulsion shall be permitted to thaw by exposure of the container to the temperature of the laboratory.

(*d*) After the first operation of freezing and thawing, the procedure shall be repeated twice, so that the emulsion will have been subjected to three cycles of freezing and thawing.

(*e*) After the third cycle, the emulsion may be homogeneous or may have separated into distinct layers which cannot be rendered homogeneous by stirring at laboratory temperature.

(*f*) The result of this test shall be reported as either "Homogeneous" or "Broken."

PENETRATION OF RESIDUE

36. The penetration shall be determined upon a representative portion of the residue in accordance with the Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5) of the American Society for Testing Materials.[3]

SOLUBILITY OF RESIDUE

37. The solubility in carbon disulfide shall be determined upon a representative portion of the residue in accordance with the Standard Method of Test for Determination of Bitumen (A.S.T.M. Designation: D 4) of the American Society for Testing Materials.[3]

DUCTILITY OF RESIDUE

38. The ductility shall be determined upon a representative portion of the residue in accordance with the Standard Method of Test for Ductility of Bituminous Materials (A.S.T.M. Designation: D 113) of the American Society for Testing Materials.[3]

SPECIFIC GRAVITY OF RESIDUE

39. The specific gravity shall be determined upon a representative portion of the residue in accordance with the Standard Method of Test for Specific Gravity of Road Oils, Road Tars, Asphalt Cements, and Soft Tar Pitches (A.S.T.M. Designation: D 70) of the American Society for Testing Materials.[3]

ASH IN RESIDUE

40. The ash shall be determined upon a representative portion of the residue in accordance with the rapid routine method of ash determination, as described in Section 5 of the Standard Methods of Analysis of Grease (A.S.T.M. Designation: D 128) of the American Society for Testing Materials.[3]

Standard Method of

FLOAT TEST FOR BITUMINOUS MATERIALS[1]

A.S.T.M. Designation: D 139 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 139; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the float test for bituminous materials.

Apparatus

2. (*a*) *Float.*—The float (Fig. 1) shall be made of aluminum or aluminum alloy and shall be in accordance with the following requirements:

	Min.	Normal	Max.
Weight of float, g...	37.70	37.90	38.10
Total height of float, mm.....	34.0	35.0	36.0
Height of rim above lower side of shoulder, mm.....	26.5	27.0	27.5
Thickness of shoulder, mm.....	1.3	1.4	1.5
Diameter of opening, mm.....	11.0	11.1	11.2

(*b*) *Collar.*—The collar (Fig. 1) shall be made of brass and shall be in accordance with the following requirements:

	Min.	Normal	Max.
Weight of collar, g...	9.60	9.80	10.00
Over-all height of collar, mm.....	22.3	22.5	22.7
Inside diameter at bottom, mm.....	12.72	12.82	12.92
Inside diameter at top, mm.....	9.65	9.70	9.75

The top of the collar shall screw up tightly against the lower side of the shoulder.

(*c*) *Calibration of Assembly.*—The assembled float and collar, with the collar filled flush with the bottom and weighted to a total weight of 53.2 g., shall float upon water with the rim 8.5 ± 1.5 mm. above the surface of the water. Dimensions of the apparatus additional to those required above are given in Fig. 1.

(*d*) *Thermometer.*—An A.S.T.M. Low Softening Point Thermometer, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of −2 to +80 C. or +30 to +180 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

(*e*) *Bath.*—The diameter of the bath and the depth of water shall be at least 185 mm.

Preparation of Sample

3. (*a*) The brass collar shall be placed with the smaller end on a brass plate

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1922 to 1927, being revised in 1923, 1924, 1925, and 1927. Editorially revised in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

which has been previously amalgamated with mercury by first rubbing it with a dilute solution of mercuric chloride or nitrate, and then with mercury.

(*b*) The sample shall be completely melted at the lowest possible temperature that will bring it to a sufficiently fluid condition for pouring, excepting creosote-oil residues, which shall be mixed and poured at a temperature of 100 to 125 C. It shall be stirred thoroughly until it is homogeneous and free from air bubbles. The sample shall then be poured into the collar in any convenient manner until slightly more than level with the top.

(*c*) *Asphalt and Asphalt Products.*—Asphalt and asphalt products shall be cooled to room temperature, placed in water maintained at 5 C. for 5 min., after which the surplus material shall be removed by means of a spatula, or steel knife, which has been slightly heated. The collar and plate shall then be placed in a tin cup containing ice water maintained at 5 ± 1 C., and left in this bath for at least 15 min.

(*d*) *Tar Products.*—Tar products shall be immediately immersed in ice water maintained at 5 C. for 5 min., after which the surplus material shall be removed by means of a spatula or steel knife, which has been slightly heated. The collar and plate shall then be placed in a tin cup containing ice water maintained at 5 ± 1 C., and left in this bath for at least 15 min.

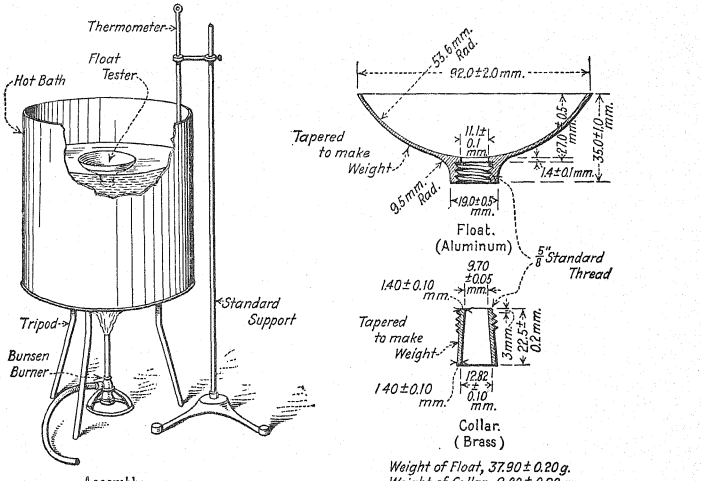

FIG. 1.—Float Test Apparatus.

Procedure

4. (*a*) The bath shall be filled with water and the water heated to the temperature at which the test is to be made. This temperature shall be accurately maintained and shall at no time throughout the test be allowed to vary more than 0.5 C. from the temperature specified.

(*b*) After the material to be tested has been kept in the ice water for not less than 15 min. nor more than 30 min., the collar with its contents shall be removed from the plate and screwed into the aluminum float and immersed in water at 5 C. for 1 min. Any water shall then be removed from the inside of the float and the latter immediately floated in the warm bath. As the plug of material becomes warm and fluid, it is forced upward and out of the collar until the water gains entrance into the saucer and causes it to sink.

(*c*) The time in seconds between placing the apparatus on the water and when the water breaks through the material shall be determined by means of a stop watch, and shall be taken as a measure of the consistency of the material under examination.

NOTE.—Special precaution should be taken to insure the collar fitting tightly into the float and to see that there is no seepage of water between the collar and float during the test.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.1-1930

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 49-42

Standard Method of Test for

PENETRATION OF BITUMINOUS MATERIALS[1]

A.S.T.M. Designation: D 5 - 25

ADOPTED, 1911; REVISED, 1916, 1921, 1925.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 5; the final number indicates the year of original adoption as standard or in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the determination of the penetration of bituminous materials.

Definition

2. Penetration is defined as the consistency of a bituminous material, expressed as the distance that a standard needle vertically penetrates a sample of the material under known conditions of loading, time, and temperature. Where the conditions of test are not specifically mentioned, the load, time, and temperature are understood to be 100 g., 5 sec., 25 C. (77 F.), respectively, and the units of penetration to indicate hundredths of a centimeter.

Apparatus

3. The apparatus shall consist of the following:

(*a*) *Container.*—A container, in which the sample is tested, made of metal or glass, cylindrical in shape, and having a flat bottom. Its inside dimensions shall be substantially as follows: 55 mm. (2.17 in.) in diameter, and 35 mm. (1.38 in.) in depth.

NOTE.—Containers known in the drug trade as seamless "ointment boxes" may be obtained in dimensions conforming to the above requirements.

(*b*) *Needle.*—A needle (Fig. 1) made from a cylindrical steel rod approximately 50.8 mm. (2 in.) in length, and 1.00 to 1.02 mm. in diameter. It shall be symmetrically tapered at one end to a cone approximately 6.35 mm. ($\frac{1}{4}$ in.) in height and whose angle shall be within the range of 8 deg. 40 min. and 9 deg. 40 min. After tapering, the point shall be "blunted" by grinding off to a truncated cone, the smaller base of which shall be from 0.14 to 0.16 mm. in diameter. The finished needle shall be hardened and highly polished.

NOTE.—The National Bureau of Standards will measure and certify the accuracy of penetration needles in accordance with the permissible variations given.

(*c*) *Water Bath.*—A water bath maintained at a temperature not varying more than 0.1 C. from 25 C. The volume of water shall be not less than 10 liters. The sample shall be immersed in the bath to a depth of not less than 10 cm.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.
[2] Editorially revised in 1939.

(4 in.) and shall be supported on a perforated shelf not less than 5 cm. (2 in.) from the bottom of the bath.

(*d*) *Penetration Apparatus.*—Any apparatus which will allow the needle to penetrate without appreciable friction, and which is accurately calibrated to yield results in accordance with the definition of penetration, will be acceptable.

(*e*) *Transfer Dish for Container.*—The transfer dish for container shall be a small dish or tray of such capacity as will insure complete immersion of the container during the test. It shall be provided with some means which will insure a firm bearing and prevent rocking of the container.

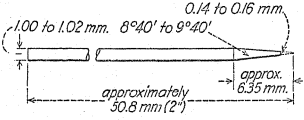

FIG. 1.—Needle for Penetration Test.

Preparation of Sample

4. The sample shall be completely melted at the lowest possible temperature and stirred thoroughly until it is homogeneous and free from air bubbles. It shall then be poured into the sample container to a depth of not less than 15 mm. ($\frac{5}{8}$ in.). The sample shall be protected from dust and allowed to cool in an atmosphere not lower than 18 C. (65 F.) for 1 hr. It shall then be placed in the water bath along with the transfer dish and allowed to remain 1 hr.

Procedure

5. (*a*) In making the test the sample shall be placed in the transfer dish filled with water from the water bath of sufficient depth to completely cover the container. The transfer dish containing the sample shall then be placed upon the stand of the penetration machine. The needle loaded with the specified weight, shall be adjusted to make contact with the surface of the sample. This may be accomplished by making contact of the actual needle point with its image reflected by the surface of the sample from a properly placed source of light. Either the reading of the dial shall then be noted or the pointer brought to zero. The needle shall then be released for the specified period of time, after which the penetration machine shall be adjusted to measure the distance penetrated.

(*b*) At least three tests shall be made at points on the surface of the sample not less than 1 cm. ($\frac{3}{8}$ in.) from the side of the container and not less than 1 cm. ($\frac{3}{8}$ in.) apart. After each test the sample and transfer dish shall be returned to the water bath and the needle shall be carefully wiped toward its point with a clean, dry cloth to remove all adhering bitumen. The reported penetration shall be the average of at least three tests whose values shall not differ more than four points between maximum and minimum.

(*c*) When desirable to vary the temperature, time and weight, and, in order to provide for a uniform method of reporting results when variations are made, the samples shall be melted and cooled in air as directed in Section 4. They shall then be immersed in water or brine, as the case may require, for 1 hr. at the temperature desired. The following combinations are suggested:

At 0 C. (32 F.)	200-g. weight, 60 sec.
At 46.1 C. (115F.)	50-g. weight, 5 sec.

ASA NO.: A37.13-1943

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 56-42

Standard Method of Test for

RESIDUE OF SPECIFIED PENETRATION[1]

A.S.T.M. Designation: D 243 – 36

ADOPTED, 1936.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 243; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the determination of percentage of residue having a specified penetration at 100 g., 5 sec., 25 C. (77 F.), obtained by heating a road oil or a semisolid asphalt having a penetration of more than 100, at a temperature of 249 to 260 C. (480 to 500 F.). When the penetration of the residue is not otherwise stated it shall be understood to be 100. The residue obtained is available for tests as desired.

Apparatus

2. The apparatus shall consist of a container, heating bath, hot plate, and thermometer, with necessary accessory apparatus as follows:

(*a*) *Container.*—The container in which the sample is to be tested shall be a flat-bottom, cylindrical seamless tin box, 70 mm. ($2\frac{3}{4}$ in. in diameter and 45 mm. ($1\frac{3}{4}$ in.) in depth.

NOTE.—Containers known in the drug trade as seamless "ointment boxes" may be obtained in dimensions conforming to the above requirements.

(*b*) *Heating Bath.*—The heating bath shall be a cast-iron air bath permitting the immersion of the container to a depth of $1\frac{1}{4}$ in. through an opening $\frac{1}{16}$ in. larger in diameter than the container. It shall support the container $\frac{1}{4}$ in. above the hot plate and with at least $\frac{1}{4}$ in. free air space between the sides of the container and of the air bath below the opening. A suitable air bath is shown in Fig. 1.

(*c*) *Hot Plate.*—The air bath shall be heated upon a suitably mounted hot plate, heated either electrically or by means of a gas flame. The plate shall be capable of maintaining the sample continuously at the required temperature, and apparatus necessary to fulfill this requirement, such as a rheostat or gas pressure regulator, shall be provided.

(*d*) *Thermometer.*—An A.S.T.M. Open Flash Thermometer, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of −6 to +400 C. or +20 to +760 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1926 to 1936, being revised in 1928, 1932, and 1935. Editorially revised in 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Preparation of Sample

3. The sample as received shall be thoroughly stirred and agitated, to insure a complete mixture before the portion for testing is removed.

Procedure

4. (*a*) A 100.00 ± 0.10-g. sample of the material to be tested shall be weighed into a tared container, which shall then be placed in the air bath in position to be heated. The thermometer shall be supported in the sample equidistant from the sides of the container and with the bottom of the bulb neither more than ¼ in. above nor touching the bottom of the container. The bulb shall be completely immersed in the sample throughout the heating. An assembly of the apparatus is shown in Fig. 2.

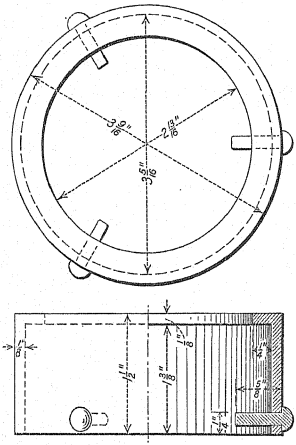

FIG. 1.—Cast-Iron Air Bath.

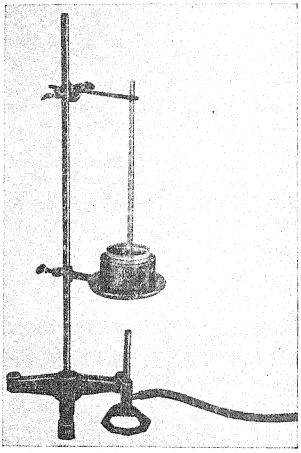

FIG. 2.—Assembly of Apparatus.

(*b*) The sample shall be heated as rapidly as possible without foaming to a temperature of 249 C. (480 F.) and during the evaporation, the temperature shall be maintained between 249 C. (480 F.) and 260 C. (500 F.). The sample shall be stirred with the thermometer from time to time to prevent local overheating and, to maintain a homogeneous sample, all cakes of hardened bitumen which form at the sides of the container shall be fluxed in the sample.

(*c*) An experienced operator can judge approximately what percentage of residue he should obtain to secure the desired penetration. When it is supposed that the residue will show the required penetration, the bitumen on the thermometer which may be readily scraped off shall be returned to the container, which then shall be removed from the air bath, cooled, and weighed. The penetration of the residue shall then be determined in accordance with the

Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5) of the American Society for Testing Materials,[3] with the exception that the 6-oz. container specified in Section 2 (*a*), in which the evaporation has been conducted, shall be used instead of the 3-oz. container specified in the Standard Method D 5.

(*d*) It frequently is necessary to make several trials before a residue of the required penetration is obtained. If it is determined to be greater than that required, all water shall be removed from the container and the surface of the sample, and the heating and determination of penetration may be repeated as before. Ordinarily, a residue shall be considered as satisfactorily obtained when its penetration is within 15 of that desired, and its percentage by weight of the original sample shall be calculated. When it is necessary to determine more precisely the percentage of residue having the specified penetration, such a percentage shall be calculated by interpolation between percentages of two residues, one having a penetration greater and one having a penetration lower than that specified. The percentage shall be reported as:

Percentage of residue of - - - - - penetration (determined - - - - - -) stating, first, the specified penetration, and second, the penetration actually determined for the sample tested or calculated by interpolation.

Precautions

5. Certain types of road oil will readily form rings of hard asphalt at the side of the container. Great care should be taken that this material be completely fluxed in the sample before the penetration of the residue is determined.

Reproducibility of Results

6. With care and proper attention to details, duplicate determinations by this method should not differ from each other by more than 1.0 per cent with the same operator nor more than 2.5 per cent between different laboratories.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: A37.10-1943
AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: T 53-42

Standard Method of Test for

SOFTENING POINT OF BITUMINOUS MATERIALS[1]

RING-AND-BALL METHOD

A.S.T.M. Designation: D 36 - 26

ADOPTED, 1919; REVISED, 1921, 1924, 1926.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 36; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Softening Point

1. The softening of bituminous materials generally takes place at no definite moment or temperature. As the temperature rises, they gradually and imperceptibly change from a brittle or exceedingly thick and slow flowing material to a softer and less viscous liquid. For this reason the determination of the softening point must be made by a fixed, arbitrary, and closely defined method if the results obtained are to be comparable.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Ring.*—A brass ring 15.875 mm. ($\frac{5}{8}$ in.) in inside diameter and 6.35 mm. ($\frac{1}{4}$ in.) in depth; thickness of wall, 2.38 mm. ($\frac{3}{32}$ in.); permissible variation on inside diameter and thickness of ring 0.25 mm. (0.01 in.). This ring shall be attached in a convenient manner to a No. 13 B. & S. gage brass wire (diameter 1.83 mm. = 0.072 in.). See Fig. 1.

(*b*) *Ball.*—A steel ball 9.53 mm. ($\frac{3}{8}$ in.) in diameter weighing between 3.45 and 3.55 g.

(*c*) *Container.*—A glass vessel, capable of being heated, not less than 8.5 cm. (3.34 in.) in diameter and measuring 10.5 cm. (4.13 in.) in depth from the bottom of the flare. (A 600-ml. beaker, low form, meets this requirement.)

(*d*) *Thermometer.*—An A.S.T.M. Low Softening Point Thermometer, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of −2 to +80 C. or +30 to +180 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

Preparation of Sample

3. The sample shall be melted and stirred thoroughly, avoiding incorporating air bubbles in the mass, and then poured into the ring so as to leave an

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1916 to 1919, being revised in 1919. Editorially revised in 1939 and 1942.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

excess on cooling. The ring, while being filled, should rest on a brass plate which has been amalgamated to prevent the bituminous material from adhering to it. After cooling 1 hr., the excess material shall be cut off cleanly with a slightly heated knife.

the sample in the water so that the lower surface of the filled ring is exactly 2.54 cm. (1 in.) above the bottom of the glass vessel and its upper surface is 5.08 cm. (2 in.) below the surface of the water. Place the ball in the water but not on the specimen. Suspend the

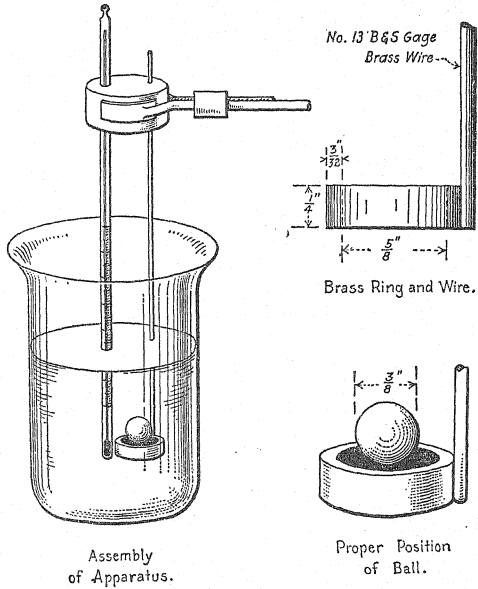

FIG. 1.—Apparatus for Ring-and-Ball Method.

Procedure for Bituminous Materials Having Softening Points 80C. (176 F.) or Below

Assembly of Apparatus

4. Fill the glass vessel to a depth of substantially 8.25 cm. (3.25 in.) with freshly boiled, distilled water at 5 C. (41 F.). Suspend the ring containing thermometer so that the bottom of the bulb is level with the bottom of the ring and within 0.635 cm. (¼ in.), but not touching the ring. Maintain the temperature of the water at 5 C. (41 F.) for 15 min. With suitable forceps, place the ball in the center of the upper surface of the bitumen in the ring, thus completing the assembly as in Fig. 1.

Heating

5. Apply the heat in such a manner that the temperature of the water is raised 5 C. (9 F.) each minute.

Softening Point

6. The temperature recorded by the thermometer at the instant the bituminous material touches the bottom of the glass vessel shall be reported as the softening point. No correction shall be made for emergent stem of the thermometer.

Permissible Variation in Rise of Temperature

7. The rate of rise of temperature shall be uniform and shall not be averaged over the period of the test. The maximum permissible variation for any minute period after the first three shall be plus or minus 0.5 C. (0.9 F.). All tests in which the rate of rise in temperature exceeds these limits shall be rejected.

Procedure for Bituminous Materials Having Softening Points Above 80 C. (176 F.)

Thermometer

8. An A.S.T.M. High Softening Point Thermometer, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of 30 to 200 C. or 85 to 392 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials[3] shall be used.

Modifications for Hard Materials

9. The same procedure as described in Sections 4 to 7 shall be employed except that U. S. P. glycerin shall be used instead of water, and the starting point of the glycerin bath shall be 32 C. (89.6 F.). The bath shall be brought to this temperature and thoroughly agitated, then the apparatus and specimens shall be placed in the bath which shall be maintained under agitation at the starting temperature for 15 min., after which the assembly shall be completed by placing the ball on the center of the specimen and the test carried on in accordance with Sections 4 to 7. In applying the heat, the ring apparatus shall be placed off the center of the container and the burner placed midway between the center and edge of the beaker away from the specimen.

Precautions

10. (*a*) The use of freshly boiled distilled water is essential, as otherwise air bubbles may form on the specimen and affect the accuracy of the results. Rigid adherence to the prescribed rate of heating is absolutely essential in order to secure accuracy of results.

(*b*) A sheet of paper placed on the bottom of the glass vessel and conveniently weighted will prevent the bituminous material from sticking to the glass vessel, thereby saving considerable time and trouble in cleaning.

Accuracy

11. The limit of accuracy of the test is plus or minus 0.5 C. (0.9 F.).

Standard Method of Test for

SOFTENING POINT OF TAR PRODUCTS[1]

CUBE-IN-WATER METHOD

A.S.T.M. Designation: D 61 – 38

ADOPTED, 1920; REVISED, 1924, 1938.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 61; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) The softening of pitch takes place at no definite moment or temperature. As the temperature rises, pitch gradually and imperceptibly changes from a brittle or exceedingly thick and slow flowing material to a softer and less viscous liquid. For this reason the determination of the softening point must be made by a fixed, arbitrary, and closely defined method if the results obtained are to be comparable.

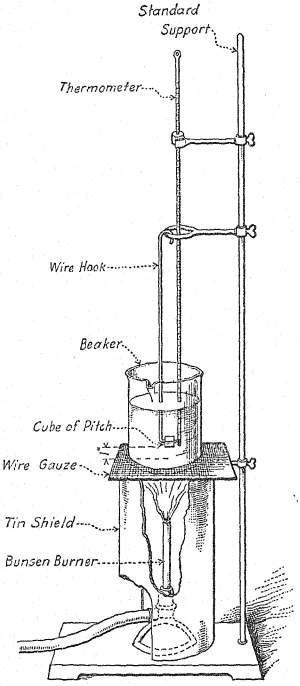
(*b*) The methods of test herein described are not applicable to pitches having softening points above 80 C. (176 F.).

(*c*) For the purpose of shortening the time required for testing, hard pitches having softening points between 43 and 80 C. (109.4 and 176 F.) are cooled at 15.5 C. (60 F.) instead of at 4 C. (39.2 F.) as prescribed for soft pitches.

Apparatus

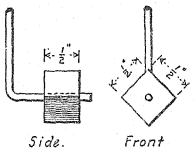
2. The apparatus shall consist of the following:

(*a*) *Mold.*—A mold suitable for forming a 12.7-mm. ($\frac{1}{2}$-in.) cube of pitch. (Suitable types are shown in Fig. 1.)



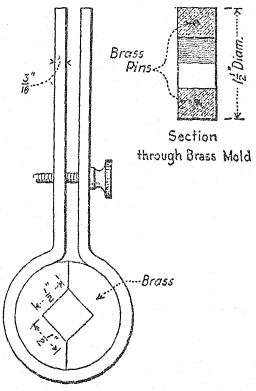
(*b*) *Hook.*—An L-shaped right-angled hook made of No. 12 B. & S. gage copper wire (diameter 2.05 mm. (0.0808 in.)) the foot of which shall be 2.54 cm. (1 in.) in length. See Fig. 1.

(*c*) *Container.*—A glass vessel, capable of being heated, not less than 8.5 cm. (3.34 in.) in diameter and measuring 10.5 cm. (4.13 in.) in depth from the bottom of the flare. (A 600-ml. beaker, Griffin low form, meets this requirement.)



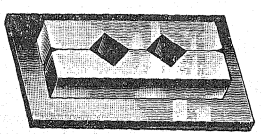
(*d*) *Thermometer.*—An A.S.T.M. Low Softening Point Thermometer, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of −2 to +80 C. or +30 to +180 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation:

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

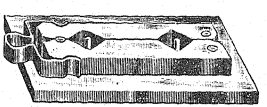


[2] Prior to adoption as standard, this method was published as tentative from 1919 to 1920. Editorially revised in 1942.

Assembly



Method of Placing Cube on Wire Hook.



Section through Brass Mold

W. I. Pitch Mold (Special)

Double Mold

Double Mold with Pins

FIG. 1.—Apparatus for Cube-in-Water Method.

E 1) of the American Society for Testing Materials.[3]

Preparation of Sample

3. The pitch shall be formed into a 12.7-mm. ($\frac{1}{2}$-in.) cube, truly shaped and with sharp edges, either by melting and pouring, or softening and pressing, into a mold. In all cases an excess of pitch shall be used and the surplus material shall be cut off cleanly with a slightly heated knife. The harder pitches specified can ordinarily be molded at room temperature, the softer pitches in water at about 4 C. (39.2 F.). If they are melted, they shall first be thoroughly stirred, avoiding incorporating air bubbles in the mass, and then poured into the mold so as to leave an excess on cooling. The mold shall rest on a brass plate and the surface of the plate and the interior surfaces of the mold should be amalgamated to prevent the pitch from adhering to them.

A. Pitches Having Softening Points Between 43 and 80 C. (109.4 and 176 F.)

Procedure

4. (*a*) The apparatus shall be assembled as shown in Fig. 1. The glass vessel shall be filled to a depth of substantially 9.5 cm. (3.75 in.) with freshly distilled water (Note 1) at 15.5 C. (60 F.). The cube of pitch shall be placed on the wire as shown in Fig. 1 and suspended in the water so that its lower edge is exactly 2.54 cm. (1 in.) above the bottom of the glass vessel and its upper edge is 5.08 cm. (2 in.) below the surface of the water. The cube shall be allowed to remain in the water for 15 min. before the heat is applied. The thermometer shall be suspended so that the bottom of the bulb is level with the bottom edge of the cube of pitch and within 0.635 cm. ($\frac{1}{4}$ in.), but not touching the cube.

(*b*) The heat shall be applied in such a manner that the temperature of the water is raised 5 C. (9 F.) each minute. The rate of rise of temperature shall be uniform and shall not be averaged over the period of the test. The maximum permissible variation for any minute period after the first three shall be plus or minus 0.5 C. (0.9 F.). All tests in which the rate of rise in temperature exceeds these limits shall be rejected. Rigid adherence to the prescribed rate of heating is absolutely essential in order to secure accuracy of results.

(*c*) *Softening Point.*—The temperature recorded by the thermometer at the instant the pitch touches the bottom of the glass vessel (Note 2) shall be reported as the softening point. No correction shall be made for emergent stem of the thermometer.

NOTE 1.—The use of freshly distilled water is essential, as otherwise air bubbles may form on the cube and retard its sinking.

NOTE 2.—A sheet of paper placed on the bottom of the glass vessel and conveniently weighted will prevent the pitch from sticking to the glass vessel, thereby saving considerable time and trouble in cleaning.

B. Pitches Having Softening Points Below 43 C. (109.4 F.)

Procedure

5. For testing pitches having softening points below 43 C. (109.4 F.) the same procedure described under method *A* in Section 4 shall be followed, except that the water when placed in the glass vessel shall be at a temperature of 4 C. (39.2 F.). The cube shall be allowed to remain 15 min. in this water before the heat is applied.

Reproducibility of Results

6. With care and proper attention to details, duplicate determinations of softening point by this method should not differ from each other by more than 1.0 C. (1.8 F.).

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Method of Test for

SPECIFIC GRAVITY OF ASPHALTS AND TAR PITCHES SUFFICIENTLY SOLID TO BE HANDLED IN FRAGMENTS[1]

A.S.T.M. Designation: D 71 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 71; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the determination of the specific gravity of asphalts and tar pitches sufficiently solid to be handled in fragments.

Specific Gravity

2. The specific gravity of asphalts and tar pitches shall be expressed as the ratio of the weight of a given volume of the material at 25 C. (77 F.) to that of an equal volume of water at the same temperature and shall be expressed thus:

Specific gravity, 25/25 C. (77/77 F.)-----.

Apparatus

3. The determination of specific gravity shall be made with an analytical balance equipped with a pan straddle or other stationary support (Fig. 1).

Test Specimen

4. The test specimen shall be a cube of the material measuring approximately ½ in. to the edge. It shall be prepared by melting a small sample of the material by the gentle application of heat, care being exercised to prevent loss by evaporation, and pouring when sufficiently fluid into a ½-in. brass cubical mold, which has been amalgamated with mercury and which is placed on an amalgamated brass plate. Precautions should be taken to prevent the inclusion of air bubbles. The hot material should slightly more than fill the mold and when cool the excess may be cut off with a hot spatula. The specimen shall be removed from the mold when cooled to room temperature.

Procedure

5. The balance shall first be tared with a piece of fine waxed silk thread sufficiently long to reach from the hook on one of the pan supports to the straddle or rest. The test specimen shall then be attached to the thread, so as to be suspended about 1 in. above the straddle from the hook on the pan support, and weighed to the nearest 0.1 mg. This

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1920 to 1927.

weight is called "*a*." The specimen, still suspended by the thread, shall then be weighed, to the nearest 0.1 mg., completely immersed in freshly boiled distilled water at 25 ± 1 C. (77 ± 1.8 F.), adhering air bubbles being first removed with a fine wire. This weight is called "*b*."

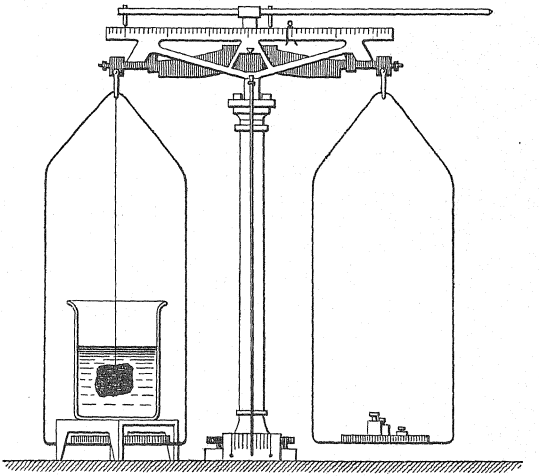


FIG. 1.—Analytical Balance Equipped with Pan Straddle.

Calculations

6. The specific gravity of the material shall be calculated from the following formula:

$$\text{Sp. gr.} = \frac{a}{a - b}$$

Accuracy

7. The limit of accuracy of the test is plus or minus 0.005 specific gravity.

Standard Method of Test for

SPECIFIC GRAVITY OF ROAD OILS, ROAD TARS, ASPHALT CEMENTS, AND SOFT TAR PITCHES[1]

A.S.T.M. Designation: D 70 - 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 70; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for the determination of the specific gravity of road oils, road tars, asphalt cements, and soft tar pitches.

Specific Gravity

2. The specific gravity of road oils, road tars, asphalt cements, and soft tar pitches shall be expressed as the ratio of the weight of a given volume of the material at 25 C. (77 F.) to that of an equal volume of water at the same temperature and shall be expressed thus:

Specific gravity, 25/25 C. (77/77 F.)----

Apparatus

3. The determination of specific gravity shall be made with a pycnometer or weighing bottle (Fig. 1), which shall consist of a straight-walled glass tube approximately 70 mm. in length and 22 mm. in diameter, carefully ground to receive an accurately fitting solid glass stopper with a hole of 1.5 to 1.7-mm. bore in place of the usual capillary opening. The lower part of the stopper shall be made concave in order to allow all air bubbles to escape through the bore. The depth of the cup-shape depression shall be about 4.8 mm. at the center. The stoppered tube shall have a capacity of about 24 ml. and when empty shall weigh not over 35 g.

Weighing Pycnometer

4. Before making a determination, the pycnometer with stopper shall first be calibrated by weighing it clean and dry upon an analytical balance. This weight is called "*a*." It shall then be filled with freshly boiled distilled water at a temperature of 25 C. (77 F.), the stopper firmly inserted, all surplus moisture wiped from the surface with a clean dry cloth and again weighed. This weight is called "*b*."

Procedure for Road Oils and Tars

5. When determining the specific gravity of road oils or road tars which flow readily, the material shall be brought to a temperature of 25 C. (77 F.) and poured into the pycnometer until it is full, with care to prevent the inclusion of air bubbles. The stopper shall then be firmly inserted and all excess of

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1920 to 1927.

material forced through the opening and carefully removed with a clean dry cloth. The pycnometer and contents shall then be weighed. This weight is called "*c*." The specific gravity of the material shall be calculated from the formula:

$$\text{Sp. gr.} = \frac{c - a}{b - a}$$

Procedure for Asphalt Cements and Pitches

6. When determining the specific gravity of tar and asphalt products which are too viscous for the method described in Section 4, a small amount of the material shall be brought to a fluid condition by the gentle application of heat, care being exercised to prevent loss

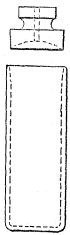

FIG. 1.—Pycnometer or Weighing Bottle.

by evaporation. When sufficiently fluid, enough of the sample shall be poured into the clean dry pycnometer to about half fill it. Precautions shall be taken to keep the material from touching the sides of the tube above the final level and to prevent the inclusion of air bubbles. The tube should be slightly warmed before filling. The pycnometer and contents shall then be cooled to room temperature and weighed with the stopper. This weight is called "*c*." The pycnometer shall next be removed from the balance, filled with freshly boiled distilled water, and the stopper firmly inserted. It shall then be completely immersed for not less than 30 min. in a beaker of distilled water maintained at 25 C. (77 F.), after which it shall be removed and all surplus water wiped off with a clean cloth. The pycnometer and contents shall then be weighed immediately. This weight is called "*d*." The specific gravity of the material shall be calculated from the formula:

$$\text{Sp. gr.} = \frac{c - a}{(b - a) - (d - c)}$$

Precautions

7. When making the specific gravity determination it is important that:

(*a*) Only freshly boiled distilled water shall be used.

(*b*) When weighing the pycnometer completely filled, the temperature of its contents shall be within 1 C. (1.8 F.) of 25 C. (77 F.).

(*c*) Precautions shall be taken to prevent expansion and overflow of the contents from the heat of the hand when wiping the surface of the pycnometer.

(*d*) The presence of all air bubbles shall be eliminated in filling the pycnometer and inserting the stopper.

(*e*) Weighings shall be made quickly after filling the pycnometer and shall be accurate to 1 mg. A number of trial fillings and catch weights may be necessary to obtain the desired degree of accuracy.

(*f*) To prevent breakage of the pycnometer when cleaning it out after a determination has been made upon a very viscous or semisolid material, it will be found advisable to warm it in an oven at not over 100 C. (212 F.) until most of the material may be poured out and then to swab it with a piece of soft cloth or cotton waste. When cool it may be finally rinsed with carbon disulfide, benzol, or other solvent and wiped clean.

Accuracy

8. The limit of accuracy of the test is plus or minus 0.005 specific gravity.

Standard Method of Test for
VISCOSITY BY MEANS OF THE SAYBOLT VISCOSIMETER[1]

A.S.T.M. Designation: D 88 – 44

ADOPTED, 1926; REVISED, 1930, 1933, 1936, 1938, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 88; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) This method of test shall be used for determining the Saybolt viscosity[3] of petroleum products and lubricants. of flow of more than 32 sec. There is no maximum limit to viscosity to be measured by the Saybolt Universal Viscosimeter but, in general, liquids having

TABLE I.—DIMENSIONS OF OIL TUBES.

Dimensions	Saybolt Universal Viscosimeter			Saybolt Furol Viscosimeter		
	Minimum, cm.	Normal, cm.	Maximum, cm.	Minimum, cm.	Normal, cm.	Maximum, cm.
Inside diameter of outlet tube	0.1750	0.1765	0.1780	0.313	0.315	0.317
Outside diameter of outlet tube at lower end	0.28	0.30	0.32	0.40	0.43	0.46
Length of outlet tube[a]	1.215	1.225	1.235	1.215	1.225	1.235
Height of overflow rim above bottom of outlet tube[a]	12.40	12.50	12.60	12.40	12.50	12.60
Outside diameter of overflow rim, at the top[a, c]	[b]		3.30	[b]		3.30
Diameter of container[a]	2.955	2.975	2.995	2.955	2.975	2.995
Depth of cylindrical part of container[a]	8.8	.....	.....	8.8	....	....
Diameter of container between bottom of cylindrical part of container and top of outlet tube[a]	0.9	.....	.....	0.9	....	....

[a] This dimension is identical in the Saybolt Universal and the Saybolt Furol instruments.
[b] The minimum value shall preferably be not less than 3.2 cm.
[c] The section of overflow rim shall be bounded by straight lines, except that a fillet is permissible at the junction with the bottom of the gallery.

(*b*) The Saybolt Universal Viscosimeter shall be used only for oils with times an outflow time of the order of 1000 sec. and higher, Saybolt Universal, are tested more conveniently by means of the Saybolt Furol Viscosimeter.

(*c*) The Saybolt Furol Viscosimeter shall be used only for oils with times of flow of more than 25 sec. The outflow time of the Furol (Note) instrument is approximately one-tenth that of the Universal.

NOTE.—The word "Furol" is a contraction of the phrase "fuel and road oils."

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-2 on Petroleum Products and Lubricants.

[2] Prior to adoption as standard, this method was published as tentative from 1921 to 1926, being revised in 1923 when it was combined with the Methods of Test for Viscosity by Means of the Saybolt Standard Universal Viscosimeter (D 47—21), and again revised in 1924, 1925, and 1926.

[3] The Conversion of Saybolt Universal Viscosity and Saybolt Furol Viscosity to Kinematic Viscosities in centistokes is covered by the Standard Method for Conversion of Kinematic Viscosity to Saybolt Universal Viscosity (A.S.T.M. Designation: D 446) and Standard Method for Conversion of Kinematic Viscosity to Saybolt Furol Viscosity (A.S.T.M. Designation: D 666), which methods appear in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Apparatus

2. The apparatus shall consist of an oil tube, bath, receiver, thermometers, timer, and withdrawal tube, conforming to the requirements specified in the following Paragraphs (*a*) to (*g*):

(*a*) *Oil Tube.*—The oil tube (illustrated in Fig. 1) shall be entirely of corrosion-resistant metal, with or without plating, and shall conform to the dimensional requirements shown in Table I

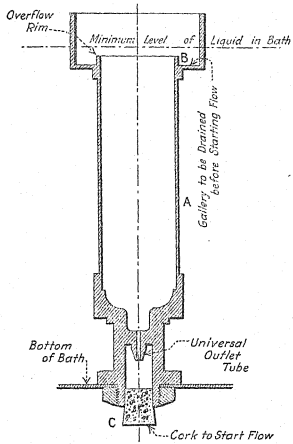

FIG. 1.—Sectional View of Standard Oil Tube.

within the permissible variations prescribed. The lower end of the oil tube shall be provided with a nut for locking it in place in the bath and with a cork or other suitable device to prevent flow until the test is started. For convenience a string or its equivalent may be attached to the cork for rapid removal.

The oil tube shall be standardized, and any correction in excess of 0.2 per cent shall be applied. The time of flow shall be within plus or minus 1 per cent (Note 1) of the time as obtained with the National Bureau of Standards' master Saybolt oil tube (Note 2).

NOTE 1.—For routine testing, oil tubes having corrections as high as plus or minus 2 per cent may be employed, provided, however, that any new oil tubes obtained after the adoption of this method shall not have corrections higher than plus or minus 1 per cent. For referee testing, oil tubes having corrections higher than plus or minus 1 per cent shall not be employed.

The oil tube may be standardized by any one of the following methods:

(*a*) Determination of outflow time for American Petroleum Institute oil standard and application of appropriate correction to obtain established value for the oil standard.

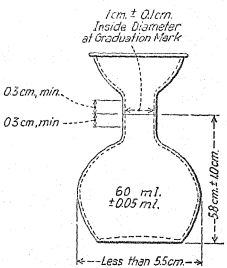

FIG. 2.—Receiving Flask.
(This type of flask is recommended as convenient and durable.)

(*b*) Calibration by National Bureau of Standards subsequent to January 1, 1935.

(*c*) Comparison with a tube certified by the National Bureau of Standards subsequent to January 1, 1935, provided the tube shows no evidence of damage or injury since certification.

NOTE 2.—This tube, conforming to the A.S.T.M. dimensional specifications, has outflow times calibrated against oil standards under the maintenance of the American Petroleum Institute Committee on Viscosity Standards.

(*b*) *Bath.*—The bath shall serve as a support to hold the oil tube in a vertical

position and as a container for the bath liquid. The bath shall be equipped with a stirring device and with means for heating or cooling. The source of heat or refrigeration shall be more than 1¼ in. (3 cm.) from the oil tube. If an external heater is used it shall be more than 2 in. (5 cm.) from the oil tube.

The bath temperature necessary to maintain thermal equilibrium (while the oil in the oil tube is well stirred by the oil-tube thermometer) shall be within plus or minus 0.1 F. (0.06 C.) of the standard temperatures of 70 F. (21.1 C.) or 77 F. (25 C.) or shall not exceed 100.25, 122.35, 130.5, 141.0, 181.5 or 212.0 F. (37.9, 50.2, 54.7, 60.6, 83.1 or 100.0 C.), respectively, for the standard temperatures mentioned in Section 3. The level of the bath liquid shall not be lower than ¼ in. (0.5 cm.) above the overflow rim of the oil tube. For referee testing the bath liquid must be one which in the bath used will meet the preceding bath-temperature conditions (Note).

NOTE.—These temperature requirements can be met with water, aqueous solutions, and some baths with oil. In routine testing oil is generally used as the bath medium. This is allowable provided the temperature of the oil bath is adjusted so that the necessary condition of thermal equilibrium is maintained. It may be necessary to maintain the oil bath at slightly higher temperatures than those specified in the preceding paragraph. Temperature differentials between oil bath and oil tube necessary to maintain thermal equilibrium may be double those given above.

(*c*) *Receiver.*—The receiving flask (see Fig. 2) shall be of glass with a capacity up to the graduation mark on its neck of 60 ± 0.05 ml. at 68 F. (20 C.). At the graduation mark, the inside diameter of the neck of the flask shall be 1 ± 0.1 cm. The cylindrical portion of the neck of the flask shall extend not less than 0.3 cm. above and below the graduation mark. The graduation mark shall be 5.8 ± 1.0 cm. above the bottom of the flask. The maximum outside diameter shall be less than 5.5 cm.

NOTE.—Many years' experience with flasks conforming to these dimensions has proved it to be satisfactory for all but the most viscous oils. With the latter, drainage errors may occur if the length of the neck of the flask above the graduation mark varies excessively. As soon as stocks of flasks now on hand have been depleted, it is planned to revise the flask's specification by limiting the length of the neck above the graduation mark to a maximum of 11 mm.

(*d*) *Oil-Tube Thermometers.*—The A.S.T.M. Saybolt Viscosity Thermometers shall include two sets of six thermometers each, one set being graduated in Fahrenheit degrees and the other in Centigrade degrees, the ranges being chosen to include the temperatures commonly used in testing as indicated in the following table. They shall conform to the requirements for these thermometers as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[4] To prevent contact of the thermometer with the orifice in the oil tube a suitable support shall be attached to the enlargement of the thermometer stem.

Temperature Range	Subdivisions	Temperature of Tests
FAHRENHEIT THERMOMETERS		
66 to 80 F.	0.2 F.	70 and 77 F.
94 to 108 F.	0.2 F.	100 F.
120 to 134 F.	0.2 F.	122 and 130 F.
134 to 148 F.	0.2 F.	140 F.
174 to 188 F.	0.2 F.	180 F.
204 to 218 F.	0.2 F.	210 F.
CENTIGRADE THERMOMETERS		
19 to 27 C.	0.1 C.	21.1 and 25 C.
34 to 42 C.	0.1 C.	37.8 C.
49 to 57 C.	0.1 C.	50 and 54.4 C.
57 to 65 C.	0.1 C.	60 C.
79 to 87 C.	0.1 C.	82.2 C.
95 to 103 C.	0.1 C.	98.9 C.

(*e*) *Bath Thermometers.*—Thermometers as specified in Paragraph (*d*) or

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

other means for measuring temperature of at least equal accuracy, shall be used in the bath.

(*f*) *Timer.*—The stop watch or other timing device used shall be graduated in divisions of 0.2 sec. or less, and shall be accurate to within 0.1 per cent when tested over a 60-min. period (Note).

NOTE.—Electrical timing devices are permissible provided they are accurate and capable of being read to 0.2 sec. Timing devices actuated by synchronous motors shall be used only on electric circuits of controlled frequency.

(*g*) *Withdrawal Tube.*—The tube or pipette used for draining the gallery shall have a smooth tip of about 3 mm. outside diameter and about 2 mm. inside diameter.

Temperature of Testing

3. (*a*) With the Saybolt Universal Viscosimeter, determinations shall be made at 70, 100, 130 or 210 F. (21.1, 37.8, 54.4 or 98.9 C.).

(*b*) With the Saybolt Furol Viscosimeter, determinations shall be made at 77. 100, 122 or 210 F. (25, 37.8, 50 or 98.9 C.). In tests on road and paving materials, determinations may also be made at 140 and 180 F. (60 and 82.2 C.).

Procedure

4. (*a*) Viscosity determinations shall be made in a room free from drafts and rapid changes in temperature. For standardization and referee tests the room shall be between 68 and 86 F (20 and 30 C.) and the actual temperature shall be recorded. For routine tests, temperatures up to 100 F. may be employed without introducing errors in excess of 1 per cent. Determinations shall not be made at temperatures below the dew point of the atmosphere surrounding the instrument.

(*b*) The oil tube shall first be cleaned with an effective solvent, such as benzol, and excess solvent shall be removed from the gallery.

(*c*) All oil shall be passed through a 100-mesh wire strainer before it is introduced into the oil tube. After the tube is cleaned, a quantity of the oil to be tested, sufficient to wet the entire surface of the tube, shall be poured into the tube and allowed to drain out (Note). The cork stopper shall be inserted not less than $\frac{1}{4}$ in. nor more than $\frac{3}{8}$ in. into the lower end of the air chamber at the bottom of the oil tube. The cork shall fit tightly enough to prevent the escape of air, as evidenced by the absence of oil on the cork after it is withdrawn.

NOTE.—The plunger commonly supplied with the viscosimeter shall never be used on instruments maintained as standards. In case the flash point is less than 50 F. (27.8 C.) above the temperature of test, the wetting operation should be omitted in order to avoid an increase in viscosity due to evaporation of a portion of the light fraction.

(*d*) If the test temperature is above that of the room, the oil shall be heated to not more than 3 F. (1.7 C.) above the temperature of test and if the temperature is below that of the room, the oil shall be cooled to not more than 3 F. (1.7 C.) below the temperature of test. In no case, however, shall the oil be preheated to a temperature above 50 F. (27.8 C.) below the flash point. The oil shall be poured into the oil tube until it ceases to overflow into the gallery. The oil in the oil tube shall be kept well stirred with the oil-tube thermometer, care being taken to avoid hitting the outflow tube. The bath temperature shall be adjusted until the oil temperature remains constant. After thermal equilibrium has been attained no further adjustments shall be made in the bath temperature. The test results shall be discarded if the indicated bath temperature varies by more than plus or minus 0.05 F. (0.03 C.) in tests at 70, 77, 100,

122 and 130 F. (21.1, 25, 37.8, 50 and 54.4 C.) or by more than plus or minus 0.10 F. (0.06 C.) in tests at 140, 180 and 210 F. (60, 82.2 and 98.9 C.).

(*e*) After the temperature of the oil in the oil tube has remained constant within 0.02 F. (0.01 C.) of the desired temperature for 1 min. with constant stirring, the oil-tube thermometer shall be withdrawn and the surplus oil removed quickly from the gallery by means of the withdrawal tube so that the level of the oil in the gallery is below the level in the oil tube proper. The tip of the withdrawal tube shall be inserted at one point in the gallery. The test shall be started over again if the tip of the withdrawal tube touches the overflow rim (see Fig. 1). Under no conditions shall the excess oil be removed by rotating the withdrawal tube around the gallery.

(*f*) The receiving flask shall be placed in position so that the stream of oil from the outlet tube will strike the neck of the flask. The graduation mark on the receiving flask shall be not less than 10 cm. nor more than 13 cm. from the bottom of the bath. The cork shall be snapped from its position and at the same instant the timer shall be started. The timer shall be stopped when the bottom of the meniscus of the oil reaches the mark on the neck of the receiving flask.

Reporting Results

5. The time in seconds as determined by the prescribed procedure, with the proper calibration correction, is the Saybolt Universal (or Saybolt Furol) viscosity of the oil at the temperature at which the test is made. Results shall be reported to the nearest 0.1 sec. for viscosity values below 200 sec. and to the nearest whole second for values 200 sec. or above.

Reproducibility of Results

6. With proper attention to details of method of procedure, results in different laboratories with different operators under referee or standardization conditions of testing, should not differ by more than 0.5 per cent.

Standard Method for

CONVERSION OF KINEMATIC VISCOSITY TO SAYBOLT FUROL VISCOSITY[1]

A.S.T.M. Designation: D 666 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 666; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. The conversion table in this method provides a means for converting kinematic viscosity in centistokes at 122 F. to Saybolt Furol viscosity in seconds at 122 F.[3]

Procedure

2. For the kinematic viscosities at 122 F. listed in Table I the equivalent Saybolt Furol viscosity in seconds at 122 F. may be read directly. For kinematic viscosities between 48 and 400 centistokes which are not listed in Table I, the equivalent Saybolt Furol viscosity values may be obtained by linear interpolation. For kinematic viscosities over 400 centistokes, the equivalent Saybolt Furol viscosity may be calculated by use of the multiplication constant given in Table I.

TABLE I.—VALUES FOR CONVERTING KINEMATIC VISCOSITY TO SAYBOLT FUROL VISCOSITY AT 122 F.

Kinematic Viscosity, centistokes	Saybolt Furol Viscosity, sec.	Kinematic Viscosity, centistokes	Saybolt Furol Viscosity, sec.	Kinematic Viscosity, centistokes	Saybolt Furol Viscosity, sec.

ASA NO.: Z11.1-1936

AMERICAN PETROLEUM INSTITUTE
STANDARD. A.P.I. NO.: 500-36

STANDARD ABRIDGED VOLUME CORRECTION TABLE FOR PETROLEUM OILS[1]

A.S.T.M. Designation: D 206 – 36

ADOPTED, 1925; REVISED, 1934, 1936.

This Standard of the American Society for Testing Materials is issued under the fixed designation D 206; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

This abridged table has been prepared by the National Bureau of Standards to meet a demand from the oil industry for a short and convenient table for reducing oil volumes to the basis of 60 F., when extreme accuracy is not required. It is not intended to replace the Bureau of Standards *Circular C 410*, but rather to supplement it and especially to replace the various abridged tables heretofore employed in the oil industry.

The groups, coefficients of expansion, gravity (degrees A.P.I.), and gravity ranges for the several subdivisions of the present abridged table are as follows:

Group Number	Coefficient of Expansion per deg. Fahr. at 60 F	Gravity, Degrees A.P.I.	Gravity Range of Group (Degrees A.P.I. at 60 F.)
0.....	0.00035	6	Up to 14.9
1.....	0.00040	22	15.0 to 34.9
2.....	0.00050	44	35.0 to 50.9
3.....	0.00060	58	51.0 to 63.9
4.....	0.00070	72	64.0 to 78.9
5.....	0.00080	86	79.0 to 88.9
6.....	0.00085	91	89.0 to 93.9
7.....	0.00090	97	94.0 to 100.0

All motor fuel blends of gasoline and benzol shall be considered as falling in Group 3. In cases of uncertainty regarding the presence of benzol, a product having a gravity heavier (numerically less) than 51° A.P.I., and a 50 per cent recovery point less than 293 F. (145 C.) shall be considered as falling in Group 3.

This table shows the volume occupied at 60 F. by a quantity of oil occupying unit volume at the indicated temperature.

For purposes of brevity the columns showing observed temperatures in degrees Fahrenheit carry the heading "t." The columns of multipliers which are actually $\left(\frac{\text{volume at 60 F.}}{\text{volume at "t"}}\right)$ carry the heading "M."

NOTE: *Example.*—The values given in the table are in the form of multipliers; that is, the volume of oil at the indicated temperature and degrees A.P.I. for each group, multiplied by the corresponding factor in the table, equals the volume at 60 F. For example, if the degrees A.P.I. of an oil at 60 F. equals 58 (Group 3) and the volume at 88 F. equals 8000 gal., then the volume at 60 F. equals 8000 × 0.9830 or 7864 gal.

[1] Under the standardization procedure of the Society, this standard is under the jurisdiction of the A.S.T.M. Committee D-2 on Petroleum Products and Lubricants.

This abridged table differs from that published in 1934 in three respects: The multipliers for Group 0 have been revised slightly; Group 1 has been extended from 249 to 499 F.; and Groups 4, 5 and 6 have been extended from 99 to 124 F.

The multipliers in the Group 0 table in the 1934 standard were taken from the National Bureau of Standards *Miscellaneous Publication No. 97.* With the revision of *Circular No. 154* (published as *Circular C 410*) to include data on oils from 0 to 10° A.P.I., it has seemed desirable to employ the procedure followed in the other groups and choose the column of multipliers from the unabridged table which has a base coefficient of expansion nearest 0.00035, which in the case of Group 0 is the column corresponding to a gravity of 6° A.P.I.

GROUP 0[a]

Legend: t = observed temperature in degrees Fahrenheit; M = multiplier for reducing oil volumes to the basis of 60 F.

[a] These tables for Group 0 and Group I have been adopted as standard by the Society as volume correction tables for asphaltic products on the joint recommendation of A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-8 on Bituminous Waterproofing and Roofing Materials.

STANDARD ABRIDGED VOLUME CORRECTION TABLE FOR PETROLEUM OILS

GROUP 1[a]

Legend: t = observed temperature in degrees Fahrenheit; M = multiplier for reducing oil volumes to the basis of 60 F.

t	M	t	M	t	M	t	M	t	M	t	M	t	M

[a] These tables for Group 0 and Group 1 have been adopted as standard by the Society as volume correction tables for asphaltic products on the joint recommendation of A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-8 on Bituminous Waterproofing and Roofing Materials.

STANDARD ABRIDGED VOLUME CORRECTION TABLE FOR PETROLEUM OILS

Group 2

Legend: t = observed temperature in degrees Fahrenheit; M = multiplier for reducing oil volumes to the basis of 60 F.

Standard Method of Test for

WATER IN PETROLEUM PRODUCTS AND OTHER BITUMINOUS MATERIALS[1]

A.S.T.M. Designation: D 95 – 40

ADOPTED, 1924; REVISED, 1927, 1928, 1930, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 95; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for use in the determination of the water in a sample of bituminous material by distilling the sample with a volatile solvent. The method is suitable for a variety of materials but is especially applicable to petroleum, fuel oil, road oil, coal tar, water-gas tar, coke-oven tar, and other petroleum products or bituminous materials.

NOTE.—For the determination of water in grease reference should be made to the procedure described in the Standard Methods of Analysis of Grease (A.S.T.M. Designation: D 128) of the American Society for Testing Materials.[3]

Apparatus

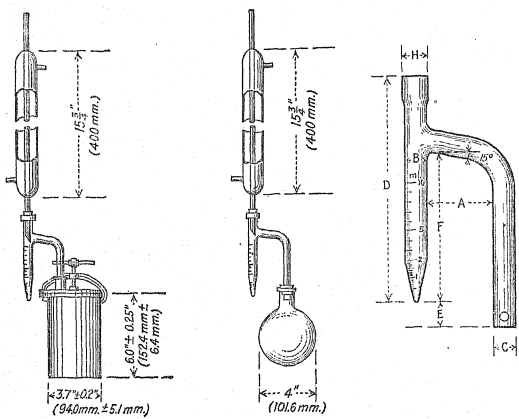
2. (*a*) The apparatus shall consist of a metal still or glass flask, heated by suitable means and provided with a reflux condenser discharging into a trap connected to the still or flask. The trap serves to collect and measure the condensed water and to return the solvent to the still. The type of distilling apparatus used is not an essential feature of this method, but glass has been generally used for petroleum products and the metal still for road materials and tars.

(*b*) *Metal Still.*—The metal still (Fig. 1 (*a*)) shall be a vertical cylindrical vessel, preferably of copper, having a faced flange at the top to which the head is tightly attached by means of a clamp. The head shall be of metal, preferably of brass or copper, and be provided with a tubulation 1 in. in inside diameter.

(*c*) *Glass Flask.*—The glass flask (Fig. 1 (*b*)) shall be of the short neck, round-bottom type, made of well-annealed glass, having an approximate capacity of 500 ml.

(*d*) *Heat Source.*—The burner used with the metal still shall be a ring gas burner 4 in. (100 mm.) in inside diameter. With the glass flask, an ordinary gas burner or electric heater may be used as the source of heat.

(*e*) *Condenser.*—The condenser shall be of the water-cooled, reflux, glass-tube type, having a condenser jacket not less



[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of A.S.T.M. Committee D-2 on Petroleum Products and Lubricants and Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1921 to 1924, being revised in 1923 and 1924.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

than 400 mm. (15¾ in.) in length, with an inner tube 9.5 to 12.7 mm. (⅜ to ½ in.) in outside diameter. The end of the condenser to be inserted in the trap shall be ground off at an angle of 30 ±5 deg. from the vertical axis of the condenser.

(*f*) *Trap.*—The trap shall be made of well-annealed glass constructed in accordance with Fig. 1 (*c*) and shall be graduated from 0 to 10 ml. in 0.1-ml. divisions. The error of any indicated capacity shall not be greater than 0.05 ml. The outside diameters should be preferably 2.5 to 3.5 mm. (3/32 to ⅛ in.) greater than the inside diameters specified.

A	45 to	55 mm	1¾ to	2⅛ in.
B (Inside Diameter)	14 to	16 mm	9/16 to	5/8 in.
C (Inside Diameter)	12 to	16 mm.	½ to	5/8 in.
D	150 to	170 mm.	6 to	6¾ in.
E	25 to	38 mm.	1 to	1½ in.
F	100 to	108 mm.	4 to	4¼ in.
H (Inside Diameter)	18 to	19 mm.	11/16 to	¾ in.

FIG. 1.—Apparatus for Determining Water.

Solvent[3a]

3. (*a*) The solvent used when testing petroleum products or bituminous materials derived from petroleum shall be petroleum naphtha and shall conform to the following distillation requirements:

5 per cent shall distill at a temperature not below 194 F. (90 C.) nor above 212 F. (100 C.)

90 per cent shall distill below 410 F. (210 C.)

(*b*) The solvent used when testing bituminous materials derived from coal tar, water-gas tar, etc., shall be coal-tar

[3a] Editorially revised in 1941.

naphtha or a light oil and shall conform to the following distillation requirement:

98 per cent shall distill between 248 F. (120 C.) and 482 F. (250 C.)	

(*c*) The distillation requirements specified for the solvents in Paragraphs (*a*) and (*b*) shall be determined in accordance with the Standard Method of Test for Distillation of Gasoline, Naphtha, Kerosine, and Similar Petroleum Products (A.S.T.M. Designation: D 86) of the American Society for Testing Materials.[3]

Sample

4. The sample shall be thoroughly representative of the material to be tested and the portion of the sample used for the test shall be thoroughly representative of the sample itself. Deviation from this requirement shall not be permitted.

NOTE.—The difficulties in obtaining proper representative samples for this determination are unusually great so that the importance of sampling cannot be too strongly emphasized.

Procedure

5. (*a*) When the sample to be tested contains less than 10 per cent of water, exactly 100 ml. of the material to be tested shall be placed into the still or flask and thoroughly mixed with an equal volume of solvent by swirling, proper care being taken to avoid any loss of material. If the material is measured by volume, an accurate 100-ml. graduated cylinder shall be used and the contents transferred to the still by rinsing with one 50-ml. portion of solvent followed by two successive 25-ml. portions of solvent, the cylinder being allowed to drain each time. When the sample to be tested contains more than 10 per cent of water, the volume of material used shall be decreased to that which will yield somewhat less than 10 ml. of water.

NOTE.—In special cases where the water content exceeds 10 per cent and it is not desirable to reduce the size of the sample to that which will yield somewhat less than 10 ml. of water, a distilling tube receiver graduated from 0 to 25 ml. may be used. This tube shall be graduated from 0 to 2 ml. in 0.1-ml. divisions and from 2 to 25 ml. in 0.2-ml. divisions (see Fig. 3 (*c*) of the Standard Methods of Testing Emulsified Asphalts (A.S.T.M. Designation: D 244) of the American Society for Testing Materials).[3]

(*b*) The connections between the still or flask, trap, and condenser shall be made by means of tight-fitting corks as shown in Figs. 1 (*a*) and (*b*). The end of the condenser inserted in the trap shall be adjusted to that position which will allow the end to be submerged to a depth of not more than 1 mm. below the surface of the liquid in the trap after distillation conditions have been established. When the metal still is used, a heavy paper gasket moistened with the solvent shall be inserted between the lid and flange before attaching the clamp. A loose cotton plug shall be inserted in the top of the condenser tube to prevent condensation of atmospheric moisture in the condenser tube.

(*c*) Heat shall then be applied and so regulated that the condensed distillate falls from the end of the condenser at the rate of from 2 to 5 drops per sec. The ring burner used with the metal still should be placed about 3 in. above the bottom of the still at the beginning of the distillation and gradually lowered as the distillation proceeds.

(*d*) The distillation shall be continued at the specified rate until no water is visible on any part of the apparatus except at the bottom of the trap. This operation usually requires less than an

hour. A persistent ring of condensed water in the condenser tube shall be removed by increasing the rate of distillation for a few minutes.

Calculations

6. The volume of condensed water measured in the trap at room temperature multiplied by 100 and divided by the volume of the sample used shall be the percentage of water and shall be reported as "- - - - per cent water by volume, A.S.T.M. Method D 95."

Reproducibility of Results

7. Duplicate determinations of water by this method should not differ from each other by more than one division on the trap.

Recommended Practice for

BITUMINOUS PAVING PLANT INSPECTION[1]

A.S.T.M. Designation: D 290 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 290; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This recommended practice defines the authority and duties of the inspector at a bituminous paving plant.

Definitions

2. (*a*) *Engineer.*—Throughout this recommended practice the term engineer shall be construed to mean the engineer in responsible charge of the work or his duly recognized or authorized laboratory; or, in the absence of an engineer, the purchaser or his duly authorized laboratory.

(*b*) *Contractor.*—The term contractor shall be construed to mean the party to the contract who has agreed to supply materials and perform work in accordance with the specifications, or his duly authorized representative at the plant.

(*c*) *Laboratory.*—The term laboratory shall be construed to mean any supervising laboratory duly authorized by the engineer to direct and advise the inspector in the discharge of his duties.

(*d*) *Plant Laboratory.*—The term plant laboratory shall be construed to mean the laboratory operated by or under the direction of the plant inspector at the plant.

RESPONSIBILITIES AND GENERAL DUTIES OF INSPECTOR

Authority

3. The inspector shall be provided with written authority from the engineer to enable him to insist on the fulfillment of specifications covering materials, plant procedure, and products; and the rejection of such materials, procedure, and products failing to conform to the specifications. The inspector shall have available a copy of the specifications applying to the particular project, and shall be furnished immediately in writing with copies of all modifications, amendments, and instructions affecting the product of the plant. The inspector shall recognize the right of the contractor to use such apparatus, methods, and personnel as he deems proper, provided

[1] Under the standardization procedure of the Society, this recommended practice is under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

[2] Prior to adoption as standard, this recommended practice was published as tentative from 1928 to 1939, being revised in 1939.

TABLE I.—INDEX OF SAMPLING BITUMINOUS PAVING MATERIALS.

Material	Method	Quantity	When Collected	By Whom Tested
Asphalt Sand	Tentative Methods of Sampling Stone, Slag, Gravel, Sand, and Stone Block for Use as Highway Materials (A.S.T.M. Designation: D 75) of the American Society for Testing Materials[a]	5 lb.	Each car or boat and truck deliveries by special instructions from preliminary or first shipments from given source, or when source or supply changes, or if change occurs in materials received	Laboratory
			Daily from subsequent shipments, and sand in use from stock pile	Plant Laboratory
Screenings	Same as for asphalt sand	5 lb.	Same as for asphalt sand	Same as for asphalt sand
Crushed Stone	Same as for asphalt sand	15 to 20 lb.	Same as for asphalt sand	Same as for asphalt sand
Filler	Composite from eight to ten sacks, mixing and quartering	5 lb.	Same as for asphalt sand	Same as for asphalt sand
Heated Aggregates	By use of shovel as aggregate flows from storage bin	5 to 20 lb., depending on whether coarse or fine aggregate	At least daily	Plant Laboratory
Asphalt Cement A	Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140) of the American Society for Testing Materials[a]	1 qt.	Each car or boat	Laboratory
Asphalt Cement B	In metal container from valve over asphalt bucket on plant. Mixed and poured into 3-oz. can	3 oz.	Daily[a]	Plant Laboratory and Laboratory
Crude Asphalt	Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140) of the American Society for Testing Materials[a]	1 qt.	Each car or boat	Laboratory
Refined Asphalt		1 qt.	Each car or boat	Laboratory
Flux		1 qt.	Each car or boat	Laboratory
Finished Mixtures A. To determine average daily analysis of mixture	Composite from number of batches	4 oz., min., for sheet asphalt; 5 lb., min., for asphaltic concrete or binder	Daily	Laboratory
Finished Mixtures B. For determination of uniformity of individual or of different batches	From individual batches	4 oz., min., for sheet asphalt; 5 lb., min., for asphaltic concrete or binder	As directed	Laboratory
Asphalt Block	Select blocks representative of production	2 blocks	Daily	Laboratory

[a] When fluxing at paving plants, preliminary 3-oz. samples shall also be taken from each melting kettle, when ready and completely mixed. This is in addition to daily 3-oz. sample as provided above.

[a] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

it is within the specifications. Any appeal on the part of the contractor from rejections shall be made in writing to the engineer, with a copy to the inspector, unless otherwise provided in the contract.

Cooperation

4. It shall be the duty of the plant inspector to cooperate in every reasonable way with the contractor so as to assist in obtaining economical and efficient plant operation; and with the pavement inspector in all plant matters relating to the economical production of a satisfactory material conforming to the specifications.

Duties

5. In addition to the responsibilities specified in Sections 3 and 4, the duties of the plant inspector shall be:

(*a*) To ascertain that the plant is equipped and operated at all times in conformity with the specifications (see Section 6),

(*b*) To collect and submit to the laboratory or to test, as directed, samples to be used at the plant (see Sections 7 to 13, inclusive, and Table I),

(*c*) To control the proportions and temperatures of mixtures and of materials within such limits as are assigned to him, and to insure that the products of the plant are otherwise in accordance with the specifications (see Sections 14 to 18),

(*d*) To conduct required plant-laboratory tests of materials (see Sections 19 to 24),

(*e*) To record the output of the plant, and, as required, the delivery and consumption of materials at the plant (see Section 25),

(*f*) To fulfill other assigned duties, (see Section 26), and

(*g*) To submit daily reports (see Sections 27 and 28).

PLANT EQUIPMENT AND OPERATION

Plant Equipment and Operation

6. The inspector shall ascertain as early as possible that the plant is equipped in accordance with specifications and capable of producing a mixture conforming to the requirements of the specifications. He shall also determine if the liners, gate, and blades of the mixer are in satisfactory condition for efficient mixing. He shall make all necessary determinations of the accuracy of scales, using standard weights, and of the volume of various containers if used in the proportioning of mixtures. During the operation of the plant, he shall check at frequent intervals the accuracy of various scales used in determining the weight of each material. He shall examine sieves used in separating heated aggregates for bin storage to see that the sieve openings are of the proper size, and that the various sieve sections are properly placed over the bins.

SAMPLING

Sampling

7. As far as possible in advance, and preferably at least three to five days before beginning work on each contract, samples of each material to be used in the mixtures shall be collected by the inspector and submitted to the laboratory or tested by him as directed as shown in Table I. Should the sources of supply of any material received change from that represented by the first sample taken by the inspector, new samples shall be submitted by the inspector.

Marking

8. Beginning at the start of operations on a given contract, the inspector shall assign class designations to each class of material being sampled, and each sample

selected shall be numbered serially in that class, continuing numerically until the completion of the work. Care shall be taken that the series of numbers is not broken or numbers duplicated. All samples sent to the laboratory shall be marked in such a manner as to insure complete identification. Letters and numbers may be scratched or punched clearly on tin cans, and marked with ink or paint on other sample containers or on sections of pavement.

Asphalt Cement

9. (*a*) Daily control samples of asphalt cement and mixtures shall be selected and, at the end of the day's work, forwarded to the laboratory without delay.

(*b*) Daily samples of asphalt cement which the inspector has tested for penetration shall be forwarded to the laboratory.

Crude Asphalt, Refined Asphalt, and Flux

10. When forwarding samples of crude asphalt, refined asphalt, and flux to the laboratory, in the inspection covering the manufacture of asphalt blocks, information shall also be furnished relative to the proportions by weight being used so that proper combination can be made for analysis and check determinations.

Sheet Asphalt Surface Mixture

11. Daily samples of sheet asphalt surface mixtures shall be obtained by the inspector for the laboratory. Each sample shall consist of small quantities from not less than ten, and preferably more, separate batches. The portions selected shall be molded into a container provided for that purpose. Care shall be taken in selecting and after collection of these samples to prevent contamination by dust or other foreign material. It is desirable to scrape away the top material in a batch before sampling to prevent any contamination.

Bituminous Concrete

12. (*a*) *Control Samples.*—Daily samples of bituminous concrete mixtures shall be taken by the inspector, using either method (1) or (2) as follows:

(1) Take small portions from a number of batches and store them on a metal plate until near the end of the day. At the end of this time heat the entire mass, taking care not to apply too high a temperature, mix thoroughly, and select the sample in small portions from this mass.

(2) Collect portions from one or more batches on a large shovel, mix thoroughly while still warm, and place a representative scoopful directly in a container. This operation shall be repeated as often as possible to represent a maximum number of batches.

Care shall be taken to avoid segregation of either stone or bituminous mortar, and in selecting the portions of the sample care shall be taken to scrape away the top material in a load so as to avoid dust or any segregated unrepresentative mixture. Precautions shall also be taken to prevent contamination, by dust or other foreign material, of the sample after collection.

(*b*) *Uniformity Samples.*—Samples shall be taken by the inspector, as directed, to show the uniformity of the mixture by either selecting three separate portions from separate distinct spots in the batch, or by selecting a representative sample from different individual batches throughout a day's run. The samples collected shall be placed in separate containers and each container shall be properly identified and distinctly marked "Uniformity Sample" furnishing also the temperature and length of time the batch was mixed.

Rejected Materials

13. Samples of all materials rejected by the inspector shall be forwarded to the laboratory.

PREPARATION OF MIXTURES

Proportioning Materials

14. Within the limits of the specifications, the inspector shall receive instructions from the engineer in regard to the desired proportion of each ingredient that enters into a mixture and the range of proportions within which he should work. It is advisable, whenever possible, to have entire loads of the mixture weighed, as a further check on the weight or volumetric proportioning being used in the plant.

Volumetric Proportioning

15. (*a*) *Dry Aggregates.*—When dry, heated sand and stone are measured by volume, their weights per cubic foot, hot, shall be determined in order to calculate the proportions. The weight per cubic foot of the filler shall also be determined, at the approximate temperature of use, for calculating the correct amount to be added.

(*b*) *Wet Aggregates.*—When wet sand, stone, and screenings are being measured by volume, the moisture content of each shall be determined by drying a representative sample and calculating the percentage of moisture. Deductions for moisture shall be made from the weights of each material forming the total batch in calculating the required amount of asphalt cement. The percentage of moisture in aggregates shall always be entered on the daily report. The determination shall be made frequently on sand and fine screenings. Loss of fine material in the drying process shall be compensated for by the use of additional filler in proportioning.

Proportioning by Weight

16. (*a*) Asphalt cement shall always be measured by weight. The actual percentage of bitumen in the asphalt cement should be ascertained from the laboratory in order to determine the proportion of asphalt cement to be used in the mixture.

(*b*) The inspector should note whether the scales on the mixing platform are being handled carefully, taking care that the aggregate hoppers and asphalt bucket swing freely during the weighing and that the beam is brought to a floating position. He should note whether the asphalt bucket is drained completely for each batch, and check the tare weight of the empty asphalt bucket at frequent intervals so as to compensate for the amount of asphalt clinging to the bucket after each pouring. Particular attention shall be paid to this point in cool weather and at times when there has been a long interval between loads.

Combining Aggregates

17. (*a*) The inspector shall give particular attention to the combination of aggregates before they enter the drier, and especially to the combination of fine aggregates. Where the proportions of the final mixture are dependent upon the supply of aggregates to a belt conveyor or elevator, he shall see that the supply of each aggregate to the conveyor is continuous and uniform. When two or more kinds of aggregate are combined on the ground and measured in such containers as wheelbarrows, which must be of equal volumes, the containers shall be struck off to a level surface. Irregular heaping shall not be permitted.

(*b*) The inspector shall make certain that the mixer operator allows mineral aggregates to become thoroughly mixed before the addition of asphalt cement, and that the time of mixing is sufficient to prepare a uniform mixture.

Temperature of Materials

18. (*a*) The inspector shall check the temperature of all ingredients of the mixture, especially mineral aggregates, and of the mixtures, as frequently as possible. He should assist plant employees in every way in keeping temperatures uniform by notifying the plant foreman of any marked changes that he may observe. Should the aggregates be of improper temperature, mixing operations shall be discontinued until aggregates of the proper temperature are obtained.

(*b*) The desired temperatures at the plant will depend upon the kind of mixture being prepared, the type of asphalt being used, weather conditions, and the length of haul. The inspector should receive instructions as to the temperature range desired for each contract.

PLANT TESTING OF MATERIALS

Sand

19. The sands shall be tested daily in accordance with the Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[3] When two or more grades of sand are being received for use in combination, separate mechanical analysis shall be made on shipments of each variety and the resultant combination calculated and shown on the daily report. The proportions in which sands are combined shall also be shown on the report.

Filler

20. Samples of the thoroughly dry filler shall be tested in accordance with the Standard Method of Test for Sieve Analysis of Mineral Filler (A.S.T.M. Designation: D 546) of the American Society for Testing Materials.[3]

Screenings

21. The mechanical analysis of screenings shall be determined on a dried sample of not less than 250 g., and if the screenings are very coarse or contain a considerable percentage of particles larger than $\frac{1}{2}$ in. in diameter, an amount up to 500 g. may be used. The sample shall be sieved on a No. 10 (2000-micron) sieve and the percentages retained on and passing this sieve shall be determined. If the amount passing the No. 10 sieve is much greater than 100 g., a portion of it, after thorough mixing, may be selected for sieve analysis by quartering and then tested as previously specified in Section 19. The percentages retained on each sieve shall be calculated on the basis of the original sample. The portion retained on the No. 10 sieve shall be sieved over various coarser sieves as may be required.

Stone

22. Coarse aggregate shall be tested for grading in accordance with the Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[3] When stone is being used from a large stock pile, frequent mechanical analyses shall be made as the work progresses.

Asphalt Cement

23. (*a*) The inspector shall make daily penetration tests of each tank of asphalt cement used in the day's work. The sample shall be placed in 3-oz. tin boxes and the test made in accordance with the Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5) of the American Society for Testing Materials.[3] After the test, all water shall be drained from the samples and the boxes closed with

tightly fitting lids for shipment to the laboratory.

(*b*) A working range of ten points penetration for the asphalt cement will usually be set by the specifications for each contract, and if results should show a deviation beyond this range a check determination shall be made. The inspector should be instructed as to what action he should take when the penetration of asphalt cement is not within the prescribed limits.

Heated Aggregates

24. Samples of aggregates which have passed through the drying and heating process shall be taken and tested at least once each day, and more frequently if necessary, to determine the uniformity of bin materials. Samples may be secured by passing a shovel or pan quickly through the stream of hot material as it flows from the storage bin. All tests of these materials shall be recorded on the plant report. The results will show: (1) when blended materials are being used, whether mixing is being carried on satisfactorily, and (2) whether separation of aggregates by sizes has been complete. If the dried sand is contaminated with stone, steps shall be taken to determine the cause and to make correction.

REPORT

Production of Plant

25. The inspector shall record daily the time and hours of operation of the plant, the number of batches and number of loads of each type of mixture produced, and also the total amounts of each material used during the day and on hand at the end of the day. At times, the inspector may be required to record the locations at which mixtures were laid on the road.

Miscellaneous Data

26. When obtainable, the inspector may be required to report cost data, inincluding the hours of work for each classification of labor, trucks, superintendents, etc., and the rates of compensation.

Daily Reports

27. At the close of each working day, whether the plant is in operation or not, the inspector shall forward to the engineer and laboratory a consecutively numbered daily report, using a form which gives all the required information. All data pertinent to the work not covered by the form should be given on the reverse side of the report sheet, and communications of exceptional importance only should be sent separately from the report. When work is suspended for several days, the inspector may not be required to submit reports daily, but the last report should state why and for what periods work has been discontinued. The inspector shall retain copies of these reports and communications and, in addition, keep a daily record of all matters pertaining to his work, particularly as to his action in acceptance or rejection of materials with reasons therefor, instructions or suggestions to the contractor, and receipt of instructions from the engineer or laboratory.

Report Form

28. A standard form of report is not practicable for all conditions and types of pavement, but the report form appearing at the end of this recommended practice is a typical form showing the kind of information which should be included; additional data may be called for as required.

Standard Definitions of

TERMS RELATING TO MATERIALS FOR ROADS AND PAVEMENTS[1]

A.S.T.M. Designation: D 8 – 33

ADOPTED, 1912; REVISED, 1915, 1918, 1932, 1933.

This Standard of the American Society for Testing Materials is issued under the fixed designation D 8; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

BITUMINOUS MATERIALS

Relating in General to Bituminous Materials

Bitumens.—Mixtures of hydrocarbons of natural or pyrogenous origin, or combinations of both, frequently accompanied by their non-metallic derivatives, which may be gaseous, liquid, semisolid, or solid, and which are completely soluble in carbon disulfide.

Bituminous.—Containing bitumen or constituting the source of bitumen.

Bituminous Emulsion.—A liquid mixture in which minute globules of bitumen are held in suspension in water or a watery solution.

Cut-Back Products.—Petroleum or tar residuums which have been fluxed with distillates.

Fluxes.—Bituminous materials, generally liquid, in which the predominating constituent is bitumen, used in combination with asphalts for the purpose of softening the latter.

Liquid Bituminous Materials.—Those, having a penetration at 25 C. (77 F.), under a load of 50 g. applied for 1 sec., of more than 350.

Semisolid Bituminous Materials.—Those having a penetration at 25 C. (77 F.), under a load of 100 g. applied for 5 sec., of more than 10, and a penetration at 25 C. (77 F.), under a load of 50 g. applied for 1 sec., of not more than 350.

Solid Bituminous Materials.—Those having a penetration at 25 C. (77 F.), under a load of 100 g. applied for 5 sec., of not more than 10.

Relating Specifically to Petroleum or Asphalts

Asphalts.—Black to dark-brown solid or semisolid cementitious materials which gradually liquefy when heated, in which the predominating constituents are bitumens all of which occur in the solid or semisolid form in nature or are obtained by refining petroleum, or which are combinations of the bitumens mentioned with each other or with petroleum or derivatives thereof.

[1] Under the standardization procedure of the Society, these definitions are under the jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials.

Artificial Asphalt.—Recommended that the use of term be discontinued.

Asphalt Cement.—A fluxed or unfluxed asphalt specially prepared as to quality and consistency for direct use in the manufacture of bituminous pavements, and having a penetration at 25 C. (77 F.) of between 5 and 250, under a load of 100 g. applied for 5 sec.

Liquid Asphalt.—This is a trade term not subject to definition.

Native Asphalt.—Asphalt occurring as such in nature.

Road Asphalt.—This is a trade term not subject to definition.

Rock Asphalt.—Sandstone or limestone naturally impregnated with asphalt.

Petroleum.—Liquid bitumen occurring as such in nature.

Blown Petroleums.—Semisolid or solid products produced primarily by the action of air upon liquid native bitumens which are heated during the blowing process.

Topped Petroleum.—Petroleum deprived of its more volatile constituents.

Asphaltenes.—The components of the bitumen in petroleums, petroleum products, malthas, asphalt cements, and solid native bitumens, which are soluble in carbon disulfide but insoluble in paraffin naphthas.

Carbenes.—The components of the bitumen in petroleums, petroleum products, malthas, asphalt cements, and solid native bitumens, which are soluble in carbon disulfide but insoluble in carbon tetrachloride.

Relating Specifically to Tars and Pitches

Tars.—Black to dark-brown bituminous condensates which yield substantial quantities of pitch when partially evaporated or fractionally distilled, and which are produced by destructive distillation of organic material, such as coal, oil, lignite, peat, and wood.

Coal Tar.—Tar produced by the destructive distillation of bituminous coal.

Gas-House Coal Tar.—Coal tar produced in gas-house retorts in the manufacture of illuminating gas from bituminous coal.

Coke-Oven Tar.—Coal tar produced in by-product coke ovens in the manufacture of coke from bituminous coal.

Oil-gas Tars.—Tars produced by cracking oil vapors at high temperatures in the manufacture of oil gas.

Water-Gas Tars.—Tars produced by cracking oil vapors at high temperatures in the manufacture of carburetted water-gas.

Dehydrated Tars.—Tars from which all water has been removed.

Refined Tar.—Tar freed from water by evaporation or distillation which is continued until the residue is of desired consistency; or a product produced by fluxing tar residuum with tar distillate.

Dead Oils.—Oils with a density greater than water which are distilled from tars.

Pitches.—Black or dark-brown solid cementitious residues which gradually liquefy when heated and which are produced by the partial evaporation or fractional distillation of tars.

Straight-run Pitch.—A pitch run to the consistency desired, in the initial process of distillation, without subsequent fluxing.

Free Carbon in Tars.—Organic matter which is insoluble in carbon disulfide.

Relating Specifically to Tests

Normal Temperature.—As applied to laboratory observations of the physical characteristics of bituminous materials, is 25 C. (77 F).

Consistency.—The degree of solidity or fluidity of bituminous materials.

Fixed Carbon.—The organic matter of the residual coke obtained upon burning hydrocarbon products in a covered vessel in the absence of free oxygen.

Penetration.—The consistency of a bituminous material expressed as the distance that a standard needle vertically penetrates a sample of the material under known conditions of loading, time and temperature. Where the conditions of test are not specifically mentioned, the load, time, and temperature are understood to be 100 g., 5 sec., and 25 C. (77 F.), respectively, and the units of penetration to indicate hundredths of a centimeter.

Viscosity.—The measure of the resistance to flow of a bituminous material, usually stated as the time of flow of a given amount of the material through a given orifice.

NONBITUMINOUS MATERIALS

Relating in General to Nonbituminous Materials

Aggregate.—The inert material, such as sand, gravel, shell, slag, or broken stone or combinations thereof, with which the cementing material is mixed to form a mortar or concrete.

Matrix.—The binding material or mixture of binding material and fine aggregate in which the large aggregate is embedded or held in place.

Crusher-Run.—The total unscreened product of a stone crusher.

Stone Chips.—Small angular fragments of stone containing no dust.

Tailings.—Stones which after going through the crusher do not pass through the largest openings of the screen.

Rubble.—Rough stones of irregular shapes and sizes, broken from larger masses either naturally or artificially, as by geological action, in quarrying, or in stone cutting or blasting.

Relating Specifically to Materials

Bank Gravel.—Gravel found in natural deposits, usually more or less intermixed with fine material, such as sand or clay, or combinations thereof; gravelly clay, gravelly sand, clayey gravel and sandy gravel, indicate the varying proportions of the materials in the mixture.

Clinker.—Generally a fused or partly fused by-product of the combustion of coal, but also including lava and portland-cement clinker, and partly vitrified slag and brick.

Chert.—Compact siliceous rock formed of calcedonic or opaline silica, or both.

Granite.—A granitoid igneous rock consisting of quartz, orthoclase, more or less oligoclase, biotite and muscovite.

Granitoid.—A textural term to describe those igneous rocks which are entirely composed of recognizable minerals.

Slag.—Fused or partly fused compounds of silica in combination with lime or other bases, resulting in secondary products from the reduction of metallic ores.

Soil.—A mixture of fine earthy material with more or less organic matter resulting from the growth and decomposition of vegetation or animal matter.

Relating Specifically to Tests

Mesh.—The square opening of a sieve.

Screen.—In laboratory work an apparatus, in which the apertures are circular, for separating sizes of material.

Sieve.—In laboratory work an apparatus, in which the apertures are square, for separating sizes of material.

Standard Method of

PREPARING SOIL SAMPLES FOR MECHANICAL ANALYSIS AND DETERMINATION OF SUBGRADE SOIL CONSTANTS[1]

A.S.T.M. Designation: D 421 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 421; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method covers the preparation of soil samples as received from the field for mechanical analysis and the determination of the subgrade soil constants.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance sensitive to 0.1 g.

(*b*) *Mortar.*—A mortar and rubber-covered pestle suitable for breaking up the aggregations of soil particles.

(*c*) *Sieves.*—A series of sieves, of square mesh woven wire cloth, conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3] The sieves required are as follows:

No. 4 (4760-micron)
No. 10 (2000-micron)
No. 40 (420-micron)
No. 200 (74-micron)

(*d*) *Sampler.*—A riffle sampler or sample splitter, for quartering the samples.

Sampling

3. The soil sample as received from the field shall be dried thoroughly in the air and the aggregations shall then be thoroughly broken up in the mortar with a rubber-covered pestle. A representative test sample of the amount required to perform the desired tests shall then be selected by the method of quartering or by the use of a sampler. The amounts of material required to perform the individual tests are as follows:

(*a*) *Mechanical Analysis.*—For the mechanical analysis, material passing a No. 10 (2000-micron) sieve is required in amounts equal to 115 g. of sandy soils and 65 g. of either silt or clay soils.

(*b*) *Physical Tests.*—For the physical tests, material passing the No. 40 (420-

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

micron) sieve is required in total amount equal to 200 g., allocated as follows:

Test	Grams
Liquid limit	30
Plastic limit	15
Centrifuge moisture equivalent	10
Field moisture equivalent	50
Volumetric shrinkage	30
Check tests	65

Preparation of Test Sample

4. (*a*) That portion of the air-dried sample selected for purpose of tests shall be weighed and the weight recorded as the weight of the total test sample uncorrected for hygroscopic moisture. The test sample shall be separated by sieving with a No. 10 (2000-micron) sieve. That fraction retained on the No. 10 sieve shall be ground in a mortar with a rubber-covered pestle until the aggregations of soil particles are broken up into the separate grains. The ground soil shall then be separated into two fractions by sieving with a No. 10 sieve.

(*b*) That fraction retained after the second sieving shall be washed free of all fine material, dried, and weighed. This weight shall be recorded as the weight of coarse material. The coarse material after being washed and dried shall be sieved on the No. 4 (4760-micron) sieve and the weight retained on the No. 4 sieve recorded.

Test Sample for Mechanical Analysis

5. The fractions passing the No. 10 (2000-micron) sieve in both sieving operations shall be thoroughly mixed together, and by the method of quartering or the use of a sampler a portion weighing approximately 115 g. for sandy soils and approximately 65 g. for silt and clay soils shall be selected for mechanical analysis.

Test Sample for Subgrade Soil Constants

6. The remaining portion of the material passing the No. 10 (2000-micron) sieve shall then be separated into two parts by means of a No. 40 (420-micron) sieve. The fraction retained on the No. 40 sieve shall be discarded. The fraction passing the No. 40 sieve shall be used for the determination of the subgrade soil constants.

Standard Method of

MECHANICAL ANALYSIS OF SOILS[1]

A.S.T.M. Designation: D 422 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 422; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method describes a procedure for the quantitative determination of the distribution of particle sizes in soils.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Balance.*—A balance sensitive to 0.1 g.

(*b*) *Stirring Apparatus.*—A special stirring apparatus (Fig. 1) with replaceable stirring paddle (Fig. 2) and specially designed dispersion cup of either of the designs shown in Fig 3.

(*c*) *Hydrometer.*—A hydrometer graduated in grams of soil per liter of suspension (Fig. 4, *A*) *or* a hydrometer with special shape bulb, graduated in specific gravity, having a range of 0.995 to 1.050 sp. gr. and reading 1.000 at 67 F. (19.4 C.) (Fig. 4, *B*).

(*d*) *Glass Graduate.*—A glass graduate 18 in. in height and 2½ in. in diameter, and graduated for a volume of 1000 ml.

(*e*) *Thermometer.*—A Fahrenheit thermometer accurate to 1 F. (0.5 C.).

(*f*) *Sieves.*—A series of sieves, of square mesh woven wire cloth, conforming to the requirements of the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3] The sieves required are as follows:

No. 20 (840-micron)
No. 40 (420-micron)
No. 60 (250-micron)
No. 140 (105-micron)
No. 200 (74-micron)

(*g*) *Water Bath.*—A water bath for maintaining the soil suspension at a constant temperature during the hydrometer analysis. A satisfactory device is an insulated zinc tank which maintains the temperature of the suspension of faucet-water temperature. Such a device is illustrated in Fig. 5.

(*h*) *Beaker.*—A tall-form beaker of 400-ml. capacity.

Sample

3. A sample of soil shall be selected by the method of quartering or by the

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

A "tentative revision" of this standard appears in the Tentative Revisions of Standards section at the back of this book.

use of a sampler from the material passing the No. 10 (2000-micron) sieve. The weight of each sample shall be approximately 115 g. for sandy soils and 65 g. for silt or clay soils and shall be obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

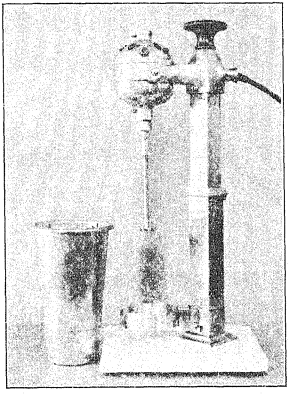

FIG. 1.—Stirring Apparatus.

HYGROSCOPIC MOISTURE

Hygroscopic Moisture

4. A 10-g. portion of the sample selected for mechanical analysis shall be used for the determination of the hygroscopic moisture. This portion of the sample shall be weighed, dried to constant weight in an oven at 110 C., weighed, and the results recorded.

HYDROMETER TEST

Dispersion of Soil Sample

5. The remainder of the sample selected for mechanical analysis shall be weighed and dispersed by one of the two methods *A* or *B* described below. The method to be used depends on the plasticity index of the soil determined in accordance with the Standard Method of Test for Plastic Limit and Plasticity Index of Soils (A.S.T.M. Designation: D 424) of the American Society for Testing Materials.[3]

Method A: For Soils Having a Plasticity Index of 20 or Less.—The soil shall

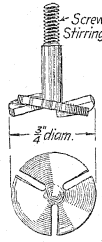

FIG. 2.—Detail of Stirring Paddle.

be placed in a tall-form beaker, and 200 ml. or more of distilled water added slowly and while stirring constantly until the soil is thoroughly wetted. The mixture shall be allowed to stand for a period of at least 18 hr. It shall then be washed into the special dispersion cup and distilled water added until the cup is within 2 in. of being filled. A deflocculating agent, 20 ml. of a solution of sodium silicate crystals ($Na_2SiO_3 \cdot 9H_2O$), shall be added. The density of this solution shall be that indicated by one of the following hydrometer readings: hydrometer *A*, 36.5 at 67 F. (19.4 C.);

hydrometer *B*, 1.023 at 67 F. (19.4 C.); Baumé hydrometer, 3 deg. at 76 F. (24.4 C.). The contents of the cup shall be mixed by the special stirring apparatus (Note) for a period of 1 min.

Method B: For Soils Having a Plasticity Index Greater Than 20.—The soil shall be placed in a tall-form beaker, and 100 ml. of hydrogen peroxide (6 per cent) added slowly and while stirring constantly until the soil is thoroughly wetted. The beaker shall then be covered with a watch glass and placed in an oven at 110 C. for 1 hr. The purpose of the peroxide is to assist in the dispersion rather than to remove the organic matter. The beaker shall then be removed from the oven, 100 ml. of distilled water added, and the mixture allowed to stand for at least 18 hr. The mixture shall then be washed into the special dispersion cup, and dispersed (Note) in the same manner and for the same length of time as in method *A*.

NOTE.—It is important in all cases to see that the paddle on the dispersion machine is replaced as soon as it shows signs of wear.

Hydrometer Test

6. (*a*) After dispersion, the mixture shall be transferred to the glass graduate, and distilled water having the same temperature as the constant temperature bath added until the mixture attains a volume of 1000 ml. The graduate containing the soil suspension shall then be placed in the constant temperature bath. The suspension shall be stirred frequently with a glass rod to prevent settlement of particles in suspension. When the soil suspension attains the temperature of the bath the graduate shall be removed and its contents thoroughly shaken for 1 min., the palm of the hand being used as a stopper over the mouth of the graduate.

(*b*) At the conclusion of this shaking the time shall be recorded, the graduate

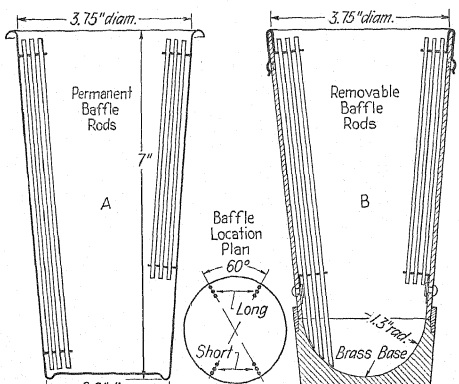

FIG. 3.—Dispersion Cups.

placed in the bath, and readings taken with the hydrometer at the end of both 1 and 2 min. The hydrometer shall be read at the top of the meniscus formed by the suspension around its stem. If hydrometer *A* is used, it shall be read to the nearest 0.5 g. per liter. Hydrometer *B* shall be read to the nearest

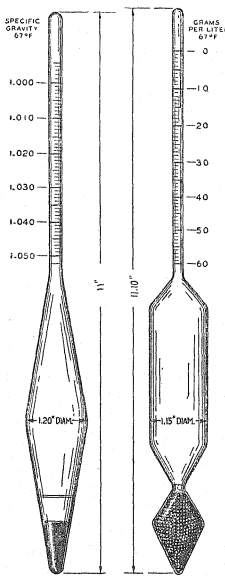

FIG. 4.—Hydrometers.

0.0005 specific gravity. Subsequent readings shall be taken at intervals of 5, 15, 30, 60, 250, and 1440 min. after the beginning of sedimentation. Readings on the thermometer placed in the constant temperature bath shall be made coincidentally with the hydrometer readings and recorded.

(*c*) After each reading except the 1-min. reading, the hydrometer shall be very carefully removed from the soil suspension in such a manner as to cause no disturbance in the suspension, wiped clean, and laid aside. About 15 or 20 sec. before the time for a reading it shall again be slowly and carefully placed in the soil suspension. The reading shall not be taken until the hydrometer has come to rest.

SIEVE ANALYSIS

Sieve Analysis

7. At the conclusion of the final reading the suspension shall be washed on a No. 200 (74-micron) sieve. That fraction retained on the No. 200 sieve shall be dried and then analyzed in a nest of sieves consisting of one each of the Nos. 20, 40, 60, 140, and 200 which conform to Section 2(*f*).

CALCULATIONS

Hygroscopic Moisture

8. The hygroscopic moisture shall be expressed as a percentage of the weight of the oven-dried soil and shall be determined as follows:

$$\text{Hygroscopic moisture} = \frac{W - W_1}{W_1} \times 100$$

where:

W = weight of air-dried soil, and
W_1 = weight of oven-dried soil.

To correct the weight of the air-dried sample of hygroscopic moisture the given value shall be multiplied by the expression:

$$\frac{100}{100 + \text{percentage of hygroscopic moisture}}$$

Coarse Material

9. (*a*) The percentage of coarse material shall be obtained from the data recorded during the preparation of the

sample in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

(*b*) The coarse material shall be determined as follows: From the weight of the air-dried total test sample subtract the weight of the oven-dried fraction retained on the No. 10 (2000-micron) sieve. The difference is assumed to equal the weight of the air-dried fraction passing the No. 10 sieve (Note 1). The weight of the fraction passing the No. 10 sieve shall be corrected for hygroscopic moisture as indicated in Section 8. To this value shall be added the weight of the oven-dried fraction retained on the No. 10 sieve to obtain the weight of the total test sample corrected for hygroscopic moisture. The fractions retained on both the No. 4 (4760-micron) and the No. 10 (2000-micron) sieve shall be expressed as percentages of the corrected weight of the total test sample (Note 2).

NOTE 1.—According to this assumption, no hygroscopic moisture is contained in the air-dried particles retained on the No. 10 sieve, when as a matter of fact a small percentage of moisture may be present in this fraction. This amount of moisture, compared with that held in the pores of the fraction passing the No. 10 sieve, is relatively small. Therefore, any error produced by the assumption as stated may be considered negligible in amount.

NOTE 2: *Example.*—The following illustration is an example of the data used in calculating the hygroscopic moisture and percentage of coarse material:

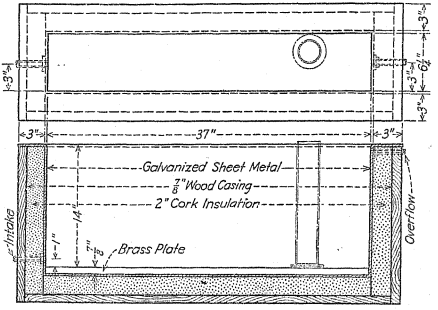

FIG. 5.—Insulated Water Bath.

Hygroscopic Moisture

Weight of air-dried soil, g	15.00
Weight of oven-dried soil, g	14.63
Hygroscopic moisture, percentage of weight of oven-dried soil	2.53
Hygroscopic moisture correction factor	0.975

Coarse Material

Weight of total test sample, air-dried, g	318.3
Weight of washed and oven-dried fraction retained on No. 10 (2000-micron) sieve, g	56.2
Weight of fraction passing No. 10 sieve, air-dried, g	262.1
Weight of fraction passing No. 10 sieve corrected for hygroscopic moisture, g	255.5
Weight of total test sample corrected for hygroscopic moisture, g	311.7
Weight of fraction retained on No. 4 (4760-micron) sieve, oven-dried, g	40 6
Fraction retained on No. 4 sieve, percentage of corrected weight of total test sample	13.0
Fraction retained on No. 10 sieve, percentage of corrected weight of total test sample	18.0

Percentage of Soil in Suspension

10. (*a*) For temperatures of the constant temperature bath other than that at which the hydrometers were cali-

brated, the readings of hydrometer *A* shall be corrected by adding temperature-correction factors such as are shown graphically as Δ R in Fig. 6 (*a*). A temperature-correction curve of this type should be determined experimentally for each hydrometer of type *A* used.

(*b*) Readings of hydrometer *B* shall be corrected by adding temperature-correction factors shown as Δ R in Fig. 6 (*b*). The temperature-correction curve for hydrometer *B* may be determined by plotting the differences between the density of water at the various temperatures and that at 67 F. (19.4 C.) against temperatures from 40 to 100 F. (4.4 to 37.8 C.).

(*c*) The percentage of the dispersed soil in suspension represented by different corrected hydrometer readings depends upon both the amount and the specific gravity of the soil dispersed. The percentage of dispersed soil remaining in suspension may be calculated as follows:

For hydrometer *A*:

$$P = \frac{Ra}{W} \times 100$$

For hydrometer *B*:

$$P = \frac{1606\,(R - 1)a}{W} \times 100$$

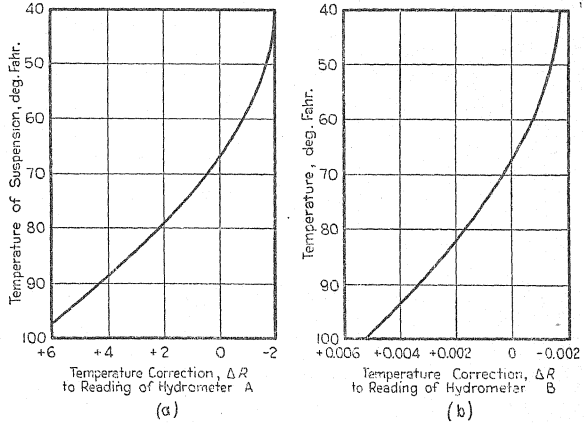

FIG. 6.—Temperature-Correction Curves for Hydrometer Readings.

where:

P = percentage of originally dispersed soil remaining in suspension,

R = corrected hydrometer reading,

W = weight in grams of soil originally dispersed minus the hygroscopic moisture, and

a = constant depending on the density of the suspension.

For hydrometer *A*, the value of *a*, for a specific gravity *G* and a water density at 67 F. (19.4 C.) of 0.9984, may be obtained from the following formula:

$$a = \frac{2.6500 - 0.9984}{2.6500} \times \frac{G}{G - 0.9984}$$

For hydrometer *B*, the value of *a* for an assumed density of 1.0000 at 67 F. (19.4 C.) may be obtained from the following formula:

$$a = \frac{2.6500 - 1.0000}{2.6500} \times \frac{G}{G - 1.0000}$$

The values of *a* given by the two equations for different values of the specific gravity of soil *G*, are the same to two decimal places, and are as follows:

Specific Gravity, *G*	Constant, *a*
2.95	0.94
2.85	0.96
2.75	0.98
2.65	1.00
2.55	1.02
2.45	1.05
2.35	1.08

It is sufficiently accurate for ordinary tests to select the constant for the specific gravity nearest to that of the particular soil tested.

Example.—Assume that the weight of dispersed soil corrected for hygroscopic moisture is 48.5 g., the uncorrected reading of hydrometer *A* is 34, the specific gravity 2.41, and the temperature of suspension 70 F. (21 C.). The temperature correction is then +0.4 (Fig. 6 (*a*)) and the corrected reading, *R*, is 34 + 0.4 = 34.4. The specific gravity correction, *a*, is 1.05. Then:

$$P = \frac{34.4 \times 1.05}{48.5} \times 100 = 74.5.$$

(*d*) The percentage of the total test sample, including the fraction retained on the No. 10 (2000-micron) sieve, shall be obtained by multiplying the percentage of originally dispersed soil remaining in suspension by the expression:

$$\frac{100 - \text{percentage retained on No. 10 sieve}}{100}$$

Diameter of Soil Particles in Suspension

11. (*a*) The maximum diameter of the particles in suspension, corresponding to the percentage indicated by a given hydrometer reading, shall be as indicated by Stokes' law.

TABLE I.—MAXIMUM GRAIN DIAMETERS IN SUSPENSION UNDER ASSUMED CONDITIONS.

Time, min.	Maximum Grain Diameter in Suspension, mm.
1	0.078
2	0.055
5	0.035
15	0.020
30	0.014
60	0.010
250	0.005
1440	0.002

According to Stokes' law:

$$d = \sqrt{\frac{30nL}{980\,(G - G_1)\,T}}$$

where:

d = maximum grain diameter in millimeters,
n = coefficient of viscosity of the suspending medium (in this case water) in poises. Varies with changes in temperature of the suspending medium.
L = distance in centimeters through which soil particles settle in a given period of time,
T = time in minutes, period of sedimentation,
G = specific gravity of soil particles,
G_1 = specific gravity of the suspending medium (in this case G_1 = 0.9984, or approximately 1.0).

(*b*) The maximum grain diameters in suspension for assumed conditions and corresponding to the periods of sedimentation specified in this procedure are given in Table I. These grain diameters

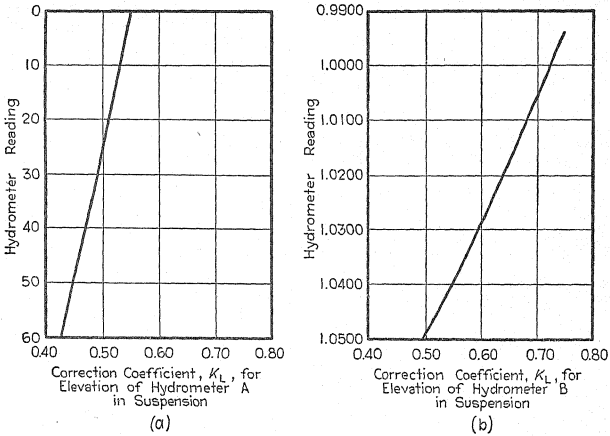

FIG. 7.—Correction Coefficient Curves for Elevation of Hydrometer.

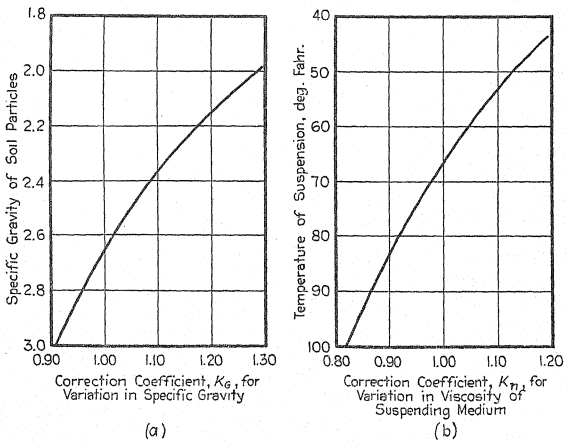

FIG. 8.—Correction Coefficient Curves for Specific Gravity and Viscosity.

shall be corrected for the conditions of the test by applying the proper correction factors as described and explained below.

(*c*) The grain diameters given in Table I are calculated according to the following assumptions:

L, the distance through which the particles fall, is constant and equal to 32.5 cm.

n, the coefficient of viscosity, equals 0.0102, that of water at 67 F. (19.4 C.).[4]

G, the specific gravity of the soil particles, is constant and equal to 2.65.

NOTE.—As a matter of fact, the hydrometer reading is dependent, not on the particles distributed throughout a depth of 32.5 cm. in the suspension, but on those existing in that portion of the suspension holding the hydrometer.

(*d*) In order to use Stokes' law to determine the diameter of the particles it is necessary to know the distance through which these particles fall in a given time. Since the density throughout a suspension is not uniform and varies with the grading of the material in suspension and the time of sedimentation, a fixed distance cannot be used. For hydrometer *B* the depth of the center of volume of the hydrometer below the surface of the suspension can be taken as the distance through which the particles may be assumed to fall. In the case of hydrometer *A*, it has been found by experiment that for the methods of dispersion described in this procedure an assumed distance which bears a constant ratio to the depth of the hydrometer in the suspension, but which is less than the distance indicated by the center of volume of the hydrometer, gives closer agreement to mechanical analysis performed by the pipette methods. The assumed distance of fall is taken as 0.42 of the distance from the surface of the suspension to the elevation of the bottom of hydrometer *A*.

(*e*) The specific gravity of the soil particles and the temperature of the suspension are likely to vary from those assumed in the preparation of Table I. A better approximation of the true diameters of the soil particles is obtained by applying correction coefficients to the values given by Table I.

(*f*) Curves from which these coefficients may be derived are given in Figs. 7 and 8. The correction coefficients for elevation of hydrometer (Fig. 7 (*a*) and (*b*)) are obtained experimentally for each hydrometer in use. The coefficients for the specific gravity and the viscosity correction (Fig. 8 (*a*) and (*b*), respectively) are independent of the apparatus used in the test.

(*g*) Multiplication by the coefficients shown in Fig. 7 (*a*) and (*b*) gives the maximum grain size at the reference elevation of hydrometers *A* and *B*, respectively, instead of that at a depth of 32.5 cm. These coefficients vary with the hydrometer reading and may be obtained from the following formula:

$$K_L = \sqrt{\frac{\text{assumed depth of fall in cm.}}{32.5}}$$

(*h*) Multiplication by the coefficients shown in Fig. 8 (*a*) corrects for variation in specific gravity from that on which the sizes given in Table I are based. These coefficients may be obtained from the following formula:

$$K_a = \sqrt{\frac{1.65}{\text{sp. gr. of soil particle} - 1}}$$

(*i*) Multiplication by the coefficients shown in Fig. 8 (*b*) corrects for the viscosity of water at temperatures other than 67 F. (19.4 C.), the temperature of the suspension assumed in the preparation of Table I. The viscosity correc-

[4] *Smithsonian Physical Tables*, 7th revised edition, 1921, p. 155.

tion coefficient may be obtained from the following formula:

$$K_n = \sqrt{\frac{n_1}{0.0102}}$$

where n_1 = viscosity coefficient at given temperature.

Example.—After a period of sedimentation of 1 min. the grain diameter indicated by Table I is 0.078 mm. Assume that the uncorrected reading of hydrometer *A* is 34, the specific gravity is 2.41, and the temperature of the suspension is 70 F. (21 C.). The correction coefficients in this case are 0.48, corresponding to a hydrometer reading of 34 (Fig. 7 (*a*)); 1.08, corresponding to a specific gravity of 2.41 (Fig. 8 (*a*)); and 0.98, corresponding to a water temperature of 70 F. (21 C.) (Fig. 8 (*b*)). The corrected grain diameter then becomes:

d = 0.078 mm. × 0.48 × 1.08 × 0.98 = 0.040 mm.

Sieve Analysis

12. (*a*) The percentage of the dispersed soil sample retained on each of the sieves in the sieve analysis shall be obtained by dividing the weight of fraction retained on each sieve by the oven-dry weight of the dispersed soil and multiplying by 100.

(*b*) The percentages of the total test sample, including the fraction retained on the No. 10 (2000-micron) sieve, shall be obtained by multiplying these values by the expression:

$$\frac{100 - \text{percentage retained on No. 10 sieve}}{100}$$

Plotting

13. The percentages of grains of different grain diameters shall be plotted on semilogarithmic paper to obtain a "soil grain diameter accumulation curve." A curve of this character is shown in Fig. 9.

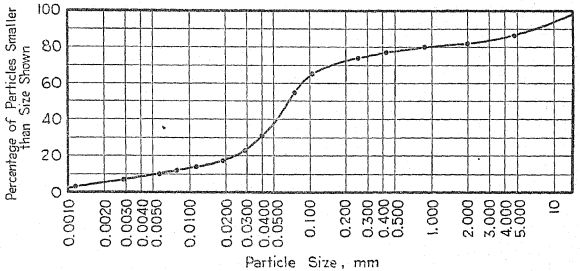

FIG. 9.—Grain Size Accumulation Curve, Soil Sample No. 4422X.

Report

14. The results, read from the accumulation curve, shall be reported as follows:

(*a*) Percentage of particles larger than 2 mm.

(*b*) Percentage of coarse sand, 2.0 to 0.25 mm.

(*c*) Percentage of fine sand, 0.25 to 0.05 mm.

(*d*) Percentage of silt, 0.05 to 0.005 mm.

(*e*) Percentage of clay, smaller than 0.005 mm.

(*f*) Percentage of colloids, smaller than 0.001 mm.

Standard Method of Test for

LIQUID LIMIT OF SOILS[1]

A.S.T.M. Designation: D 423 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 423; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Liquid Limit

1. The liquid limit of a soil is that moisture content, expressed as a percentage of the weight of the oven-dried soil, at which the soil will just begin to flow when lightly jarred ten times.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Evaporating Dish.*—A porcelain evaporating dish about 4½ in. in diameter.

(*b*) *Spatula.*—A spatula or pill knife having a blade about 3 in. in length and about ¾ in. in width.

(*c*) *Liquid Limit Device.*—A mechanical device consisting of a brass dish and carriage, constructed according to the plan and dimensions shown in Fig. 1.

(*d*) *Grooving Tool.*—A combined grooving tool and gage conforming to the dimensions shown in Fig. 1.

(*e*) *Containers.*—Suitable containers such as matched watch glasses which will prevent loss of moisture during weighing.

(*f*) *Balance.*—A balance sensitive to 0.1 g.

HAND METHOD

Sample

3. A sample weighing about 30 g. shall be taken from the thoroughly mixed portion of the material passing the No. 40 (420-micron) sieve which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

Procedure

4. (*a*) The air-dried soil shall be placed in the evaporating dish and thoroughly mixed with distilled water until the mass becomes a thick paste. The mass of soil shall then be shaped into a small layer about ⅜ in. in thickness at the center and divided into two portions with the grooving tool, as shown in the illustration at the top of Fig. 2.

(*b*) The dish shall be held firmly in

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1936 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

one hand, with the groove parallel to the line of sight, and tapped lightly with a horizontal motion against the heel of the other hand ten times. The intensity of the blows shall be such that the effect on the soil sample is equivalent to that produced by 25 shocks applied to a sample of the soil at the same moisture content by dropping the brass cup of the mechanical device through a distance of the liquid limit, and dry soil shall be added and the procedure repeated.

(*d*) When the lower edges of the two portions of the soil cake just flow together, as shown in the illustration at the bottom of Fig. 2, after ten blows have been struck, the moisture content equals the liquid limit. To determine definitely whether the two portions are actually joined, the spatula may be used to push

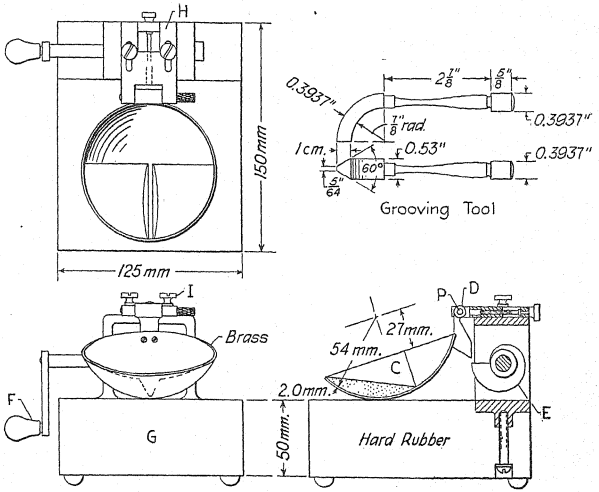

FIG. 1.—Liquid Limit Device.

1 cm. (0.3937 in.) at the rate of two drops per second.

(*c*) If the lower edges of the two soil portions do not flow together, as shown in the illustration at the bottom of Fig. 2, after ten blows have been struck, the moisture content is below the liquid limit. More water shall be added and the procedure repeated. If the lower edges meet before ten blows have been struck, the moisture content is above one away from the other. If the two portions separate along the original line of division, the end point has not been reached, and the procedure shall be repeated with the addition of a small amount of water.

(*e*) A small quantity of soil from that portion of the soil cake which was flowed shall be removed and placed in a pair of watch glasses or other suitable containers. The container and soil shall

then be weighed and the weight recorded. The soil in the container shall be oven-dried to constant weight at 110 C., and weighed. This weight shall be recorded and the loss in weight due to drying shall be recorded as the weight of water.

Calculation

5. The liquid limit is expressed as the moisture content in percentage of the weight of the oven-dried soil and shall be calculated as follows:

$$\text{Liquid limit} = \frac{\text{wt. of water}}{\text{wt. of oven-dry soil}} \times 100$$

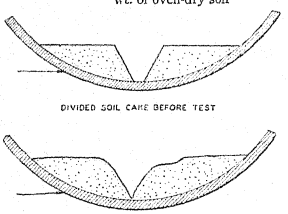

FIG. 2.—Diagram Illustrating Liquid Limit Test.

MECHANICAL METHOD

Calibration of Mechanical Device

6. By means of the gage attached to the grooving tool, and the adjustment plate, *H*, Fig. 1, the height to which the cup, *C*, is lifted shall be adjusted so that the point on the cup which comes in contact with the base is exactly 1 cm. (0.3937 in.) above the base. The adjustment plate, *H*, shall then be secured by tightening the screws, *I*.

Procedure

7. (*a*) A sample weighing about 100 g. shall be taken from the thoroughly mixed portion of the air-dried soil passing the No. 40 (420-micron) sieve which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3] This sample shall be placed in the evaporating dish and thoroughly mixed with a measured quantity of distilled water to a putty-like consistency. A portion of this sample shall then be placed in the brass cup in the position shown in Fig. 1, leveled off to a depth of 1 cm., and divided by means of the grooving tool along the diameter through the centerline of the cam follower.

(*b*) The cup shall then be attached to the carriage and by turning the crank, *F*, at the rate of two rotations per second lifted and dropped until the two sides of the sample come into contact at the bottom of the groove along a distance of about ½ in. The number of shocks shall be recorded. The moisture content of the soil shall then be determined on a portion taken from around the groove, by the method previously described in Section 4 in connection with the hand method.

(*c*) The foregoing operations shall be repeated for two additional portions of the sample to which sufficient water has been added to bring the soil to a more fluid condition. The object of this procedure is to obtain samples of such consistency that the number of shocks required to close the groove will be below and above 25.

Preparation of Flow Curve

8. A "flow curve" representing the relation between moisture contents and corresponding numbers of shocks shall be plotted on a semilogarithmic graph with the moisture contents as abscissae on the arithmetical scale, and the numbers of shocks as ordinates on the logarithmic scale.

Liquid Limit

9. The moisture content corresponding to the intersection of the flow curve with the 25 shock ordinate shall be taken as the liquid limit of the soil.

Standard Method of Test for

PLASTIC LIMIT AND PLASTICITY INDEX OF SOILS[1]

A.S.T.M. Designation: D 424 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 424; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Plastic Limit

1. The plastic limit of a soil is the lowest moisture content, expressed as a percentage of the weight of the oven-dried soil, at which the soil can be rolled into threads $\frac{1}{8}$ in. in diameter without the threads breaking into pieces.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Evaporating Dish.*—A porcelain evaporating dish about $4\frac{1}{2}$ in. in diameter.

(*b*) *Spatula.*—A spatula or pill knife having a blade about 3 in. in length and about $\frac{3}{4}$ in. in width.

(*c*) *Surface for Rolling.*—A ground-glass plate or piece of rough-textured paper on which to roll the sample.

(*d*) *Containers.*—Suitable containers, such as matched watch glasses, which will prevent loss of moisture during weighing.

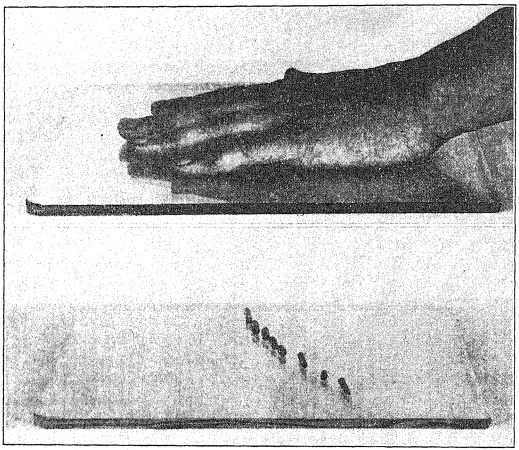
(*e*) *Balance.*—A balance sensitive to 0.1 g.

Sample

3. A sample weighing about 15 g. shall be taken from the thoroughly mixed portion of the material passing the No. 40 (420-micron) sieve, which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

Procedure

4. The air-dried soil shall be placed in the evaporating dish and mixed with distilled water until the mass becomes plastic enough to be easily shaped into a ball. The ball of soil shall then be rolled between the palm of the hand and the ground-glass plate or piece of rough-textured paper with just sufficient pressure to form the soil mass into a thread (Fig. 1 (*a*)). When the diameter of the resulting thread becomes $\frac{1}{8}$ in. the soil shall be kneaded together and again rolled out. This process shall be con-



[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

tinued until the crumbling of the soil (as shown in Fig. 1 (*b*)) prevents the formation of the thread. The portions of the crumbled soil shall then be gathered together and placed in watch glasses or other suitable containers. The container and soil shall be weighed and the weight recorded. The soil in the container shall then be oven-dried to constant weight at 110 C., and weighed. This weight shall be recorded and the loss in weight shall be recorded as the weight of water.

(a) Rolling of soil threads in plastic limit test.

(b) Crumbled soil threads resulting from plastic limit test.

FIG. 1.—Plastic Limit Test.

Calculation

5. (*a*) *Plastic Limit.*—The plastic limit is expressed as the moisture content in percentage of the weight of the oven-dry soil and shall be calculated as follows:

$$\text{Plastic limit} = \frac{\text{wt. of water}}{\text{wt. of oven-dry soil}} \times 100$$

(*b*) *Plasticity Index.*—The plasticity index of a soil is the difference between its liquid limit and its plastic limit and shall be calculated as follows:

$$\text{Plasticity index} = \text{liquid limit} - \text{plastic limit}$$

NOTE.—Liquid limit shall be determined in accordance with the Standard Method of Test for Liquid Limit of Soils (A.S.T.M. Designation: D 423) of the American Society for Testing Materials.[3]

Standard Method of Test for

CENTRIFUGE MOISTURE EQUIVALENT OF SOILS[1]

A.S.T.M. Designation: D 425 – 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 425; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Centrifuge Moisture Equivalent

1. The centrifuge moisture equivalent of a soil is the amount of moisture, expressed as a percentage of the weight of the oven-dried soil, retained by the soil which has been first saturated with water and then subjected to a force equal to 1000 times the force of gravity for 1 hr.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Gooch Crucible.*—A porcelain Gooch crucible with perforated bottom. The crucible shall be about $1\frac{1}{2}$ in. in height and the diameter shall be about 1 in. at the top and $\frac{3}{4}$ in. at the bottom, outside dimensions.

(*b*) *Filter Paper.*—A circular piece of filter paper just large enough to cover the inside bottom of the Gooch crucible.

(*c*) *Trunnion Cup.*—A Babcock trunnion cup fitted with a brass cap and with a suitable device for supporting the Gooch crucible $\frac{1}{2}$ in. above the bottom of the cup in such a manner that the water ejected during the centrifuging operation shall not come in contact with the crucible and contents and, furthermore, that air may circulate freely about the crucible within the cup. Suitable fittings for the Babcock cup are shown in Fig. 1.

(*d*) *Centrifuge.*—The centrifuge shall be of such size and so driven that a force equal to 1000 times the force of gravity may be exerted on the center of gravity of the soil sample.

(*e*) *Balance.*—A balance sensitive to 0.1 g.

Sample

3. A 5-g. sample shall be taken from the thoroughly mixed portion of the material passing the No. 40 (420-micron) sieve which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Number of Tests

4. Tests shall be made in duplicate.

Procedure

5. (*a*) The sample shall be placed in the Gooch crucible, in which has previously been placed a piece of wet filter paper which just covers the bottom of the crucible. The crucible shall be placed in a pan of distilled water and the sample allowed to take up moisture until completely saturated, as indicated by the presence of free water on the surface of the sample. It shall then be placed in a humidifier for at least 12 hr. to insure uniform distribution of moisture throughout the soil mass. All free water then remaining on the surface of the sample shall be poured off, and the crucible placed in a Babcock trunnion cup fitted as described in Section 2 (*c*).

(*b*) The sample shall be centrifuged for a period of 1 hr. at a speed which, for the diameter of head used, will exert a centrifugal force 1000 times the force of gravity upon the center of gravity of the soil sample. Immediately after centrifuging, the crucible and contents shall be weighed and the weight recorded as the weight of crucible and contents after centrifuging. The sample shall then be oven-dried to constant weight at 110 C., and weighed. This weight shall be recorded as the weight of crucible and contents after drying.

(*c*) *Waterlogging.*—When free water is observed on the top of the sample after the centrifuging operation, the soil is said to have waterlogged. This water shall not be removed but shall be weighed with the sample.

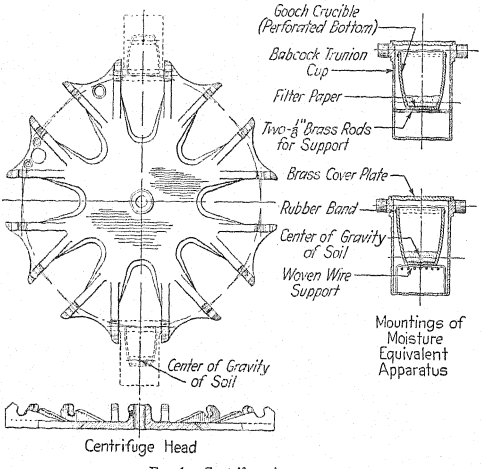


FIG. 1.—Centrifuge Apparatus.

Calculation

6. The centrifuge moisture equivalent of the soil shall be calculated as follows:

$$M_e = \frac{(A - b) - (A_1 - b_1)}{A_1 - (c + b_1)} \times 100$$

where:

M_e = centrifuge moisture equivalent,
A = weight of crucible and contents after centrifuging,
A_1 = weight of crucible and contents after drying,
c = weight of crucible,
b = weight of wet filter paper, and
b_1 = weight of dry filter paper.

Reproducibility of Results

7. The variation between the two values obtained in the duplicate tests should not exceed 1 per cent for values of the moisture equivalent up to 15 and 2 per cent for values above 15.

Standard Method of Test for

FIELD MOISTURE EQUIVALENT OF SOILS[1]

A.S.T.M. Designation: D 426 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 426; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Field Moisture Equivalent

1. The field moisture equivalent of a soil is defined as the minimum moisture content, expressed as a percentage of the weight of the oven-dried soil, at which a drop of water placed on a smoothed surface of the soil will not immediately be absorbed by the soil but will spread out over the surface and give it a shiny appearance.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Evaporating Dish.*—A porcelain evaporating dish about 4½ in. in diameter.

(*b*) *Spatula.*—A spatula or pill knife having a blade about 3 in. in length and about ¾ in. in width.

(*c*) *Pipette.*—A pipette, burette, or similar device for adding water dropwise.

(*d*) *Containers.*—Suitable containers such as matched watch glasses which will prevent loss of moisture during weighing.

(*e*) *Balance.*—A balance sensitive to 0.1 g.

Sample

3. A sample weighing about 50 g. shall be taken from the thoroughly mixed portion of the material passing the No. 40 (420-micron) sieve, which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

Procedure

4. The air-dried sample shall be placed in the evaporating dish and mixed with distilled water. Distilled water shall be added in small amounts and the sample thoroughly mixed after each addition of water. When the wetted soil forms into balls under manipulation, the sample shall be smoothed with a light stroke of the spatula and a drop of water placed on the smoothed surface. If the drop of water disappears in 30 sec. a

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

small increment of water (a few drops) shall be mixed with the sample, and the procedure repeated until the drop of water does not disappear in 30 sec. but spreads over the smoothed surface leaving a shiny appearance. A small portion of the soil on which the last drop of water was placed shall then be removed and placed between two watch glasses or other suitable containers. The weight of the container and wet soil shall be determined and recorded. The sample shall then be oven-dried to constant weight at 110 C., and weighed. This weight shall be recorded and the difference in weight shall be recorded as the weight of water.

Calculation

5. The field moisture equivalent shall be calculated as follows:

$$\text{Field moisture equivalent} = \frac{\text{wt. of water}}{\text{wt. of oven-dried soil}} \times 100$$

Standard Method of Test for

SHRINKAGE FACTORS OF SOILS[1]

A.S.T.M. Designation: D 427 - 39

ADOPTED, 1939.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 427; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for obtaining the data from which the following subgrade soil constants may be calculated:

Shrinkage limit,
Shrinkage ratio,
Volumetric change,
Lineal shrinkage, and
Specific gravity (approximate).

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Evaporating Dish.*—A porcelain evaporating dish about $4\frac{1}{2}$ in. in diameter.

(*b*) *Spatula.*—A spatula or pill knife having a blade about 3 in. in length and about $\frac{3}{4}$ in. in width.

(*c*) *Shrinkage Dish.*—A circular porcelain or monel metal milk dish having a flat bottom and being about $1\frac{3}{4}$ in. in diameter and about $\frac{1}{2}$ in. in height.

(*d*) *Straightedge.*—A steel straightedge about 12 in. in length.

(*e*) *Glass Cup.*—A glass cup about 2 in. in diameter and about 1 in. in height, the top rim of which is ground smooth and level.

(*f*) *Glass Plate.*—A glass plate with three metal prongs for immersing the soil pat in mercury, as shown in Fig. 1.

(*g*) *Graduate.*—A glass graduate having a capacity of 25 ml. and graduated to 0.2 ml.

(*h*) *Balance.*—A balance sensitive to 0.1 g.

(*i*) *Mercury.*—Sufficient mercury to fill the glass cup to overflowing.

Sample

3. A sample weighing about 30 g. shall be taken from the thoroughly mixed portion of the material passing the No. 40 (420-micron) sieve which has been obtained in accordance with the Standard Method of Preparing Soil Samples for Mechanical Analysis and Determination of Subgrade Soil Constants (A.S.T.M. Designation: D 421) of the American Society for Testing Materials.[3]

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1935 to 1939, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Procedure

4. (*a*) The sample shall be placed in the evaporating dish and thoroughly mixed with distilled water in amount sufficient to fill the soil voids completely and to make the soil pasty enough to be readily worked into the shrinkage dish without the inclusion of air bubbles. The amount of water required to furnish friable soils with the desired consistency is equal to or slightly greater than the liquid limit, and the amount necessary to furnish plastic soils with the desired consistency

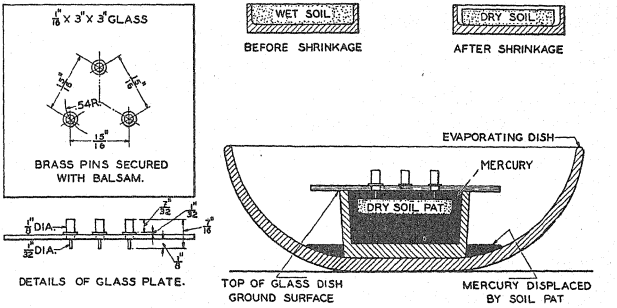

FIG. 1.—Apparatus for Determining the Volumetric Change of Subgrade Soils.

dish tapped until the soil is thoroughly compacted and all included air has been brought to the surface. More soil shall be added and the tapping shall be continued until the dish is completely filled and excess soil stands out about its edge. The excess soil shall then be struck off with a straightedge, and all soil adhering to the outside of the dish shall be wiped off.

(*c*) The dish when filled and struck off level shall be weighed immediately and the weight recorded as the weight of dish and wet soil. The soil pat shall be allowed to dry in air until the color of the pat turns from dark to light. It shall then be oven-dried to constant weight at 110 C. and weighed, the weight being recorded as the weight of dish and dry soil. The weight of the empty dish shall be determined and recorded. The capacity of the dish in cubic centimeters, which is also the volume of the wet soil pat, shall be determined by filling the dish to overflowing with mercury, removing the excess by pressing a glass plate firmly over the top of the dish, and measuring by means of a glass graduate

may exceed the liquid limit by as much as 10 per cent.

(*b*) The inside of the shrinkage dish shall be coated with a thin layer of vaseline or some other heavy grease to prevent the adhesion of the soil to the dish. An amount of the wetted soil equal to about one-third the volume of the dish shall be placed in the center of the dish, and the soil caused to flow to the edges by tapping the dish on a firm surface cushioned by several layers of blotting paper or similar material. An amount of soil shall be added approximately equal to the first portion, and the

the volume of mercury held in the dish. This volume shall be recorded as the volume of the wet soil pat, V.

(*d*) The volume of the dry soil pat shall be determined by removing the pat from the shrinkage dish and immersing it in the glass cup full of mercury in the following manner: The glass cup shall be filled to overflowing with mercury and the excess mercury shall be removed by pressing the glass plate with the three prongs (Fig. 1) firmly over the top of the cup. Any mercury which may be adhering to the outside of the cup shall be carefully wiped off. The cup, filled with mercury, shall be placed in the evaporating dish, and the soil pat shall be placed on the surface of the mercury. It shall then be carefully forced under the mercury by means of the glass plate with the three prongs (Fig. 1) and the plate shall be pressed firmly over the top of the cup. It is essential that no air be trapped under the soil pat. The volume of the mercury so displaced shall be measured in the glass graduate and recorded as the volume of the dry soil pat, V_o.

Calculation of Moisture Content

5. The moisture content of the soil at the time it was placed in the dish expressed as a percentage of the dry weight of the soil shall be calculated as follows:

$$M = \frac{W - W_0}{W_0} \times 100$$

where:

M = moisture content of the soil when placed in the dish,
W = weight of wet soil pat obtained by subtracting the weight of the shrinkage dish from the weight of the dish and wet pat, and
W_o = weight of dry soil pat obtained by subtracting the weight of the shrinkage dish from the weight of the dish and dry pat.

Shrinkage Limit

6. (*a*) The shrinkage limit of a soil is that moisture content, expressed as a percentage of the weight of the oven-dried soil, at which a reduction in moisture content will not cause a decrease in the volume of the soil mass, but at which an increase in moisture content will cause an increase in the volume of the soil mass.

(*b*) The shrinkage limit, S, shall be calculated from the data obtained in the volumetric shrinkage determination by the following formula:

$$S = M - \left(\frac{V - V_0}{W_0} \times 100 \right)$$

where:

S = shrinkage limit
M = moisture content of wet soil, in percentage of the weight of oven-dried soil,
V = volume of wet soil pat,
V_o = volume of dry soil pat, and
W_o = weight of oven-dried soil pat.

(*c*) *Optional Method.*—When both the true specific gravity, G, and the shrinkage ratio, R, are known, the shrinkage limit may be calculated as follows:

$$S = \left(\frac{1}{R} - \frac{1}{G} \right) \times 100$$

Shrinkage Ratio

7. (*a*) The shrinkage ratio of a soil is the ratio between a given volume change, expressed as a percentage of the dry volume, and the corresponding change in moisture content above the shrinkage limit, expressed as a percentage of the weight of the oven-dried

soil. It equals the apparent specific gravity of the dried soil pat.

(*b*) The shrinkage ratio, *R*, shall be calculated from the data obtained in the volumetric shrinkage determination by the following formula:

$$R = \frac{W_0}{V_0}$$

Volumetric Change

8. (*a*) The volumetric change of a soil for a given moisture content is the volume change, expressed as a percentage of the dry volume, of the soil mass when the moisture content is reduced from the stipulated percentage to the shrinkage limit. This stipulated moisture content is usually taken as the field moisture equivalent.

(*b*) The volumetric change shall be calculated from the data obtained in the volumetric shrinkage determination by the following formula:

$$\text{Volumetric change} = (M_1 - S)R$$

where M_1 = given moisture content.

If, as is customary, the volumetric change from the field moisture equivalent is desired, the formula assumes the following form:

$$\text{Volumetric change, } C_f = \text{volumetric change from field moisture equivalent}$$

$$\text{Volumetric change, } C_f = (F - S)R$$

where F = field moisture equivalent.

Lineal Shrinkage

9. (*a*) The lineal shrinkage of a soil for a given moisture content is the decrease in one dimension, expressed as a percentage of the original dimension, of the soil mass when the moisture content is reduced from an amount equal to the field moisture equivalent to the shrinkage limit.

(*b*) The lineal shrinkage shall be obtained either by means of the following formula or by means of the curve

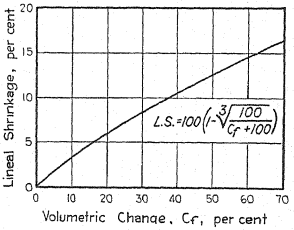

FIG. 2.—Curve for Determining Lineal Shrinkage.

shown in Fig. 2, which represents this relation:

$$\text{Lineal shrinkage} = 100\left(1 - \sqrt[3]{\frac{100}{C_f + 100}}\right)$$

Specific Gravity

10. (*a*) The specific gravity of a soil is the weight of the oven-dried soil divided by the true volume of the soil particles.

(*b*) The specific gravity may be calculated from the data obtained in the volumetric shrinkage test by the following formula:

$$\text{Sp. gr.} = \frac{1}{\frac{1}{R} - \frac{S}{100}}$$

Standard Method of Test for

MOISTURE-DENSITY RELATIONS OF SOIL-CEMENT MIXTURES[1]

A.S.T.M. Designation: D 558 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 558; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the relationship between the moisture content of soil-cement mixtures and resulting densities (oven-dry weight per cubic foot) when the soil-cement mixture is compacted in the laboratory, before cement hydration, as specified herein.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Mold.*—A cylindrical metal mold having a capacity of $\frac{1}{30}$ cu. ft. with an internal diameter of 4.0 in. and a height of approximately 4.6 in., which has a detachable collar assembly approximately $2\frac{1}{2}$ in. in height, to permit preparing compacted specimens of soil-cement mixtures 4.0 in. in diameter and approximately 4.6 in. in height which have a volume of $\frac{1}{30}$ cu. ft. The mold and collar shall be fastened to a detachable base. (See Fig. 1.)

(*b*) *Rammer.*—A metal rammer having a 2-in. diameter circular face and weighing 5.5 lb. The rammer shall be equipped with a suitable arrangement to control the specified drop.

(*c*) *Sleeve.*—Closed cylindrical sleeve slightly less than 4.0 in. in diameter or similar device for removing compacted specimens from the mold.

(*d*) *Balances.*—A balance or scale of 25-lb. capacity sensitive to 0.01 lb.; and a 100-g. capacity balance sensitive to 0.1 g.

(*e*) *Drying Oven.*—A thermostatically controlled drying oven capable of maintaining temperatures of about 110 C. (230 F.) for drying moisture samples.

Procedure

3. (*a*) The air-dry soil first shall be pulverized to pass a No. 4 (4760-micron) sieve so as to separate the soil particles without reducing the particle size.

(*b*) The required cement shall be added to the pulverized soil. The test shall be performed only on that portion of the soil-cement mixture which will

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1944.

pass a No. 4 (4760-micron) sieve. A quantity of water sufficient to produce slight cohesion shall then be thoroughly mixed with the soil-cement sample to permit ready compaction. The thoroughly mixed soil-cement sample shall be immediately compacted in the mold in three equal layers, to give a total compacted depth of about 5 in.; each layer being compacted by 25 blows of the rammer dropping free from a height of 12 in. above the elevation of the soil when a sleeve-type rammer is used or 12

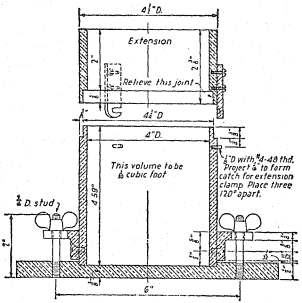

FIG. 1.—Cylindrical Mold for Moisture-Density Test.

in. above the approximate elevation of each finally compacted layer when a stationary mounted type rammer is used. During compaction, the mold shall rest on a uniform, rigid foundation weighing 200 lb. or its equivalent. The blows shall be uniformly distributed over the surface of the layer being compacted. After compacting, the collar shall be removed and the top carefully trimmed to the exact height of the mold with a steel straightedge to produce a specimen approximately 4.6 in. in height and having a volume of $\frac{1}{30}$ cu. ft.

(*c*) The weight of the compacted soil-cement mixture shall be determined, the material removed from the cylinder, sliced vertically in the center and a 100-g. sample taken from the center, weighed immediately, dried in an oven at 110 C. (230 F.) for at least 12 hr. or to constant weight. This procedure establishes the moisture-density relation of the initial soil-cement mixture.

(*d*) The soil-cement mixture shall be again finely pulverized, so as to separate the soil particles without reducing the particle size, to pass a No. 4 (4760-micron) sieve and a small increment of moisture carefully added and thoroughly mixed to insure uniform distribution. Then the moistened and pulverized material shall be compacted in the mold in three layers as described in Paragraph (*b*), weighed, and a moisture determination made to establish the moisture-density relation for a slightly moistened soil-cement mixture. The soil-cement mixture again shall be finely pulverized, so as to separate the soil particles without reducing the particle size, to pass a No. 4 sieve and additional increments of water added and the same procedure followed of mixing, compacting in the mold, weighing, and making moisture determinations until the moisture content of the soil-cement mixture reaches a condition where it is difficult to pulverize the moistened materials, or it has a moisture content near the liquid limit. This procedure will establish the moisture-density relations of a soil-cement mixture for the moisture contents practicable to handle in the field.

Calculation

4. The moisture content and oven-dry weight of the mixture as compacted shall

be calculated by means of the following formulas:

$$\text{Moisture, per cent} = \frac{\text{wt. of wet soil-cement} - \text{wt. of oven-dried soil-cement}}{\text{wt. of oven-dried soil-cement}} \times 100$$

$$\text{Dry weight (per cu. ft. of soil-cement as compacted)} = \frac{\text{wet wt. in lb. per cu. ft.}}{\text{percentage of moisture plus 100}} \times 100$$

Moisture-Density Relationship

5. (*a*) The calculations in Section 4 are made to determine the moisture content and corresponding compacted oven-dry weight (density) of the compacted soil-cement for each test made on the mixture. The oven-dry weights per cubic foot (density) of the soil shall be plotted as ordinates and the corresponding moisture contents as abscissas.

(*b*) *Optimum Moisture Content.*—When the moisture-density relations have been determined for a soil-cement mixture and the results plotted as indicated in Paragraph (*a*), it will be found that by connecting the plotted points with a smooth line a curve is produced which is, generally, parabolic in form. The moisture content producing the peak of the curve shall be termed the "optimum moisture content" of the soil-cement mixture under the above compaction.

(*c*) *Maximum Density.*—The oven-dry weight per cubic foot of moist soil-cement mixture at "optimum moisture content" shall be termed "maximum density" under the above compaction.

(*d*) When the curve resulting from connecting plotted points does not produce a parabolic-type curve with a definite peak, the "optimum moisture" and "maximum density" for such mixtures shall be determined from the results of additional tests conducted in conformance with the Standard Method of Wetting-and-Drying Test of Compacted Soil-Cement Mixtures (A.S.T.M. Designation: D 559)[3] and the Standard Method of Freezing-and-Thawing Test of Compacted Soil-Cement Mixtures (A.S.T.M. Designation: D 560)[3] on compacted soil-cement specimens. These specimens shall be molded with moisture contents approximately equal to the plastic limit of the soil and 1, 2, and 3 per cent above and below this governing moisture content. The densities of these specimens shall be those obtained with the prescribed moisture contents in the moisture-density test for the mixture. The cement content of these specimens shall be such that the soil-cement losses on the specimen giving the best results in these tests shall not exceed 10 per cent of the dry weight of the specimen. The moisture content and density corresponding to the specimen giving the best results shall be used as the "optimum moisture content" and "maximum density" of soil-cement mixtures which do not produce a parabolic-type curve.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Method of

WETTING-AND-DRYING TEST OF COMPACTED SOIL-CEMENT MIXTURES[1]

A.S.T.M. Designation: D 559 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 559; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the soil-cement losses, moisture changes, and volume changes (swell and shrinkage) produced by repeated wetting and drying of compacted specimens of soil-cement mixtures of known composition and of known uniform density and moisture content.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Mold.*—A cylindrical metal mold having a capacity of $\frac{1}{30}$ cu. ft. with an internal diameter of 4.0 in. and a height of approximately 4.6 in., which has a detachable collar assembly approximately $2\frac{1}{2}$ in. in height, to permit preparing compacted specimens of soil-cement mixtures 4.0 in. in diameter and approximately 4.6 in. in height which have a volume of $\frac{1}{30}$ cu.ft. The mold and collar shall be fastened to a detachable base. (See Fig. 1.)

(*b*) *Rammer.*—A metal rammer having a 2-in. diameter circular face and weighing 5.5 lb. The rammer shall be equipped with a suitable arrangement to control the specified drop.

(*c*) *Sleeve.*—Closed cylindrical sleeve slightly less than 4.0 in. in diameter or similar device for removing compacted specimens from the mold.

(*d*) *Balances.*—A balance or scale of 25-lb. capacity sensitive to 0.01 lb.; and a 100-g. capacity balance sensitive to 0.1 g.

(*e*) *Drying Ovens.*—A thermostatically controlled drying oven capable of maintaining temperatures of about 110 C. (230 F.) for drying moisture samples.

A thermostatically controlled drying oven capable of maintaining temperatures of about 71 C. (160 F.) for drying compacted soil-cement specimens.

(*f*) *Moist Room.*—A moist room capable of maintaining a temperature of 21 ± 1.7 C. (70 ± 3 F.) and a relative humidity of not less than 90 per cent for seven-day storage of compacted specimens.

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1944.

(*g*) *Water Bath.*—Suitable tank for submerging compacted specimens in water at about 21 C. (70 F.).

(*h*) *Wire Scratch Brush.*—A wire scratch brush made of 2-in. by $\frac{1}{16}$-in. flat No. 26 gage wire bristles assembled in 50 groups of 10 bristles each and mounted to form five longitudinal rows and ten transverse rows of bristles on a $7\frac{1}{2}$-in. by $2\frac{1}{2}$-in. hardwood block.

Preparation of Material for Molding Specimens

3. This test shall be performed on soil-cement mixtures compacted in the mold, before cement hydration, to maximum density at optimum moisture content and in the same manner of compaction as specified in the Standard Method of Test for Moisture - Density Relations of Soil-Cement Mixtures (A.S.T.M. Designation: D 558) of the American Society for Testing Materials.[3] Representative roadway soil shall be used except as modified in the following Paragraph (*b*).

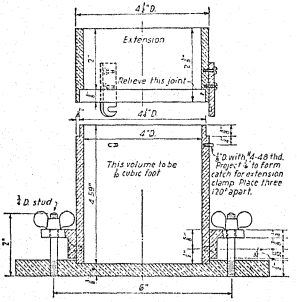

FIG. 1.—Cylindrical Mold for Molding Specimens.

(*a*) *For Soil-Cement Mixtures Containing No Material Retained on the No. 4 Sieve.*—A sufficient quantity of each soil-cement mixture to be investigated shall be prepared at optimum moisture content to provide two compacted specimens approximately 4.6 in. in height and 4.0 in. in diameter.

(*b*) *For Soil-Cement Mixtures Containing Material Retained on the No. 4 Sieve.*—When the soil-cement mixtures contain material retained on the No. 4 (4760-micron) sieve, the following procedures shall be followed which vary from that described in Paragraph (*a*): Since the specimens are 4 in. in diameter, it is necessary to prescribe the maximum size material to be used in the specimen and this size shall be set at $\frac{3}{4}$ in. Compensation shall be made for any material larger than $\frac{3}{4}$ in. by replacing it with an equal dry weight of No. 4 sieve to $\frac{3}{4}$-in. material of the same gradation as that contained in the original soil sample. A sufficient quantity of minus No. 4 sieve soil-cement material shall be prepared at the optimum moisture content to provide two compacted specimens 4.6 in. in height and 4.0 in. in diameter after the requisite amount of saturated, surface-moist, plus No. 4 sieve material, as defined above, has been added to the damp, minus No. 4 material.

Molding Specimens

4. (*a*) The prepared material shall be compacted in the mold in the same manner as that specified in the Standard Method of Test for Moisture - Density Relations of Soil-Cement Mixtures (A.S.T.M. Designation: D 558) of the American Society for Testing Materials,[3] with the further provision that before placing and compacting the next layer, smooth compaction planes produced

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

during compaction of each layer shall be scarified to form grooves, at right angles to each other, approximately $\frac{1}{2}$ in. in width and $\frac{1}{8}$ in. in depth and approximately $\frac{1}{4}$ in. apart. During compaction, a representative soil-cement mixture moisture sample shall be taken from the batch, weighed, dried in an oven at 110 C. (230 F.) for at least 12 hr. or to constant weight. The compacted specimens shall be removed from the mold, weighed, and the density determined; the volume shall be determined by (*1*) averaging the diameters measured to the nearest 0.02 in. (0.05 cm.) at right angles to each other at the center and the quarter points of the specimen and averaging the heights measured to the nearest 0.02 in. (0.05 cm.) at the quarter points on the circumference of the specimen, or (*2*) by immersion and displacement methods in a nonabsorbent liquid such as mercury.

(*b*) One specimen shall be identified on a metal tag (or other suitable device) as No. 1, together with other needed identification marks and shall be used to obtain data on moisture and volume changes during the test. The other specimen shall be identified as No. 2, together with other needed identification marks and shall be used to obtain data on soil-cement losses during this test.

(*c*) After the required data have been obtained, the specimens shall be placed on suitable carriers in the moist room and protected from free water for a period of seven days. The No. 1 specimens shall be weighed and measured daily to give data for calculating the moisture content and volume of the specimens each day.

Procedure

5. (*a*) At the end of the storage in the moist room, the specimens shall be submerged in tap water at room temperature for a period of 5 hr. and removed. The No. 1 specimen (volume and moisture change specimen) shall be weighed and measured.

(*b*) Both specimens shall be placed in an oven at about 71 C. (160 F.) for 42 hr. and removed. Then, both specimens shall be weighed and No. 1 specimen measured. Specimen No. 2 (soil-cement loss specimen) shall then be given two firm strokes on all areas with a wire scratch brush to remove all material loosened during wetting and drying. The specimen shall again be weighed after brushing. The moisture content of the material brushed from the specimen shall be determined directly, but if this is not possible, it may be assumed to be equal to the moisture content of the No. 1 specimen. The oven-dry (110 C., 230 F.) weight of material brushed from the specimen shall be calculated.

(*c*) The procedures described in Paragraphs (*a*) and (*b*) constitute one cycle (48 hr.) of wetting and drying. The specimens shall then be again submerged in water and the procedure continued. The data collected will permit calculations of volume and moisture changes of specimen No. 1 and the soil-cement losses of specimen No. 2.

(*d*) The wetting and drying of the No. 1 specimens shall be continued for 12 cycles or discontinued prior to 12 cycles should the measurements become inaccurate due to distortion or soil-cement loss of the specimens. The wetting and drying of the No. 2 specimens shall be continued for 12 cycles, if possible.

Calculation

6. The volume and moisture changes and the soil-cement losses of the specimens shall be calculated as follows:

(*a*) The difference between the volume of specimen No. 1 at the time of

molding and subsequent volumes shall be calculated as a percentage of the original volume.

(*b*) The moisture content of specimen No. 1 at the time of molding and subsequent moisture contents shall be calculated as a percentage of the original oven-dry weight of the specimen.

(*c*) The soil-cement loss of specimen No. 2 shall be calculated as a percentage of the original oven-dry weight of the specimen.

Standard Method of

FREEZING-AND-THAWING TEST OF COMPACTED SOIL-CEMENT MIXTURES[1]

A.S.T.M. Designation: D 560 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 560; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test is intended for determining the soil-cement losses, moisture changes, and volume changes (swell and shrinkage) produced by repeated freezing and thawing of compacted specimens of soil-cement mixtures of known composition and of known uniform density and moisture content.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Mold.*—A cylindrical metal mold having a capacity of $\frac{1}{30}$ cu.ft. with an internal diameter of 4.0 in. and a height of approximately 4.6 in., which has a detachable collar assembly approximately $2\frac{1}{2}$ in. in height, to permit preparing compacted specimens of soil-cement mixtures 4.0 in. in diameter and approximately 4.6 in. in height which have a volume of $\frac{1}{30}$ cu. ft. The mold and collar shall be fastened to a detachable base. (See Fig. 1.)

(*b*) *Rammer.*—A metal rammer having a 2-in. diameter circular face and weighing 5.5 lb. The rammer shall be equipped with a suitable arrangement to control the specified drop.

(*c*) *Sleeve.*—Closed cylindrical sleeve slightly less than 4.0 in. in diameter or similar device for removing compacted specimens from the mold.

(*d*) *Balances.*—A balance or scale of 25-lb. capacity sensitive to 0.01 lb.; and a 100-g. capacity balance sensitive to 0.1 g.

(*e*) *Drying Oven.*—A thermostatically controlled drying oven capable of maintaining temperatures of about 110 C. (230 F.) for drying moisture samples.

(*f*) *Freezing Cabinet.*—A freezing cabinet capable of maintaining temperatures of minus 23 C. (minus 10 F.) or lower.

(*g*) *Moist Room.*—A moist room capable of maintaining a temperature of 21 ± 1.7 C. (70 ± 3 F.) and a relative humidity of not less than 90 per cent for seven-day storage of compacted specimens and for thawing frozen specimens.

[1] Under the standardization procedure of the Society, this method is under the joint jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-18 on Soils for Engineering Purposes.

[2] Prior to adoption as standard, this method was published as tentative from 1940 to 1944.

(*h*) *Wire Scratch Brush.*—A wire scratch brush made of 2-in. by $\frac{1}{16}$-in. flat No. 26 gage wire bristles assembled in 50 groups of 10 bristles each and mounted to form five longitudinal rows and ten transverse rows of bristles on a $7\frac{1}{2}$-in. by $2\frac{1}{2}$-in. hardwood block.

Preparation of Material for Molding Specimens

3. This test shall be performed on soil-cement mixtures compacted in the mold, before cement hydration, to maximum density at optimum moisture content and in the same manner of compaction as specified in the Standard Method of Test for Moisture-Density Relations of Soil-Cement Mixtures (A.S.T.M. Designation: D 558) of the American Society for Testing Materials.[3] Representative roadway soil shall be used except as modified in the following Paragraph (*b*).

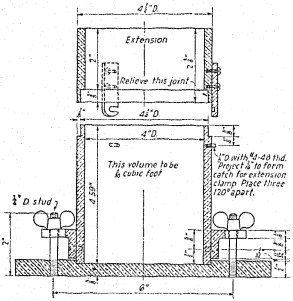

FIG. 1.—Cylindrical Mold for Molding Specimens.

(*a*) *For Soil-Cement Mixtures Containing No Material Retained on the No. 4 Sieve.*—A sufficient quantity of each soil-cement mixture to be investigated shall be prepared at optimum moisture content to provide two compacted specimens approximately 4.6 in. in height and 4.0 in. in diameter.

(*b*) *For Soil-Cement Mixtures Containing Material Retained on the No. 4 Sieve.*—When the soil-cement mixtures contain material retained on the No. 4 (4760-micron) sieve, the following procedures shall be followed which vary from that described in Paragraph (*a*): Since the specimens are 4 in. in diameter, it is necessary to prescribe the maximum size material to be used in the specimens and this size shall be set at $\frac{3}{4}$ in. Compensation shall be made for any material larger than $\frac{3}{4}$ in. by replacing it with an equal dry weight of No. 4 sieve to $\frac{3}{4}$-in. material of the same gradation as that contained in the original soil sample. A sufficient quantity of minus No. 4 sieve soil-cement material shall be prepared at optimum moisture content to provide two compacted specimens 4.6 in. in height and 4.0 in. in diameter after the requisite amount of saturated surface-moist, plus No. 4 sieve material, as defined above, has been added to the damp, minus No. 4 sieve material.

Molding Specimens

4. (*a*) The prepared material shall be compacted in the mold in the same manner as that specified in the Standard Method of Test for Moisture - Density Relations of Soil-Cement Mixtures (A.S.T.M. Designation: D 558) of the American Society for Testing Materials,[3] with the further provision that before placing and compacting the next layer, smooth compaction planes produced during compaction of each layer shall be scarified to form grooves, at right angles to each other, approximately $\frac{1}{8}$ in. in width and $\frac{1}{8}$ in. in depth and approximately $\frac{1}{4}$ in. apart. During compaction, a repre-

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

sentative soil-cement mixture moisture sample shall be taken from the batch, weighed, dried in an oven at 110 C. (230 F.) for at least 12 hr. or to constant weight. The compacted specimens shall be removed from the mold, weighed, and density determined; the volume shall be determined by (*1*) averaging the diameters measured to the nearest 0.02 in. (0.05 cm.) at right angles to each other at the center and the quarter points of the specimen and averaging the heights measured to the nearest 0.02 in. (0.05 cm.) at the quarter points on the circumference of the specimen, or (*2*) by immersion and displacement methods in a nonabsorbent liquid such as mercury.

(*b*) One specimen shall be identified on a metal tag (or other suitable device) as No. 1, together with other needed identification marks and shall be used to obtain data on moisture and volume changes during the test. The other specimen shall be identified as No. 2, together with other needed identification marks and shall be used to obtain data on soil-cement losses during this test.

(*c*) After the required data have been obtained, the specimens shall be placed on suitable carriers in the moist room and protected from free water for a period of seven days. The No. 1 specimens shall be weighed and measured daily to give data for calculating the moisture content and volume of the specimens each day.

Procedure

5. (*a*) At the end of the storage in the moist room, water-saturated felt pads, blotters or similar absorptive material shall be placed between the specimens and the carriers, and the assembly placed in a refrigerator having a constant temperature not warmer than minus 23 C. (minus 10 F.) for 22 hr. and removed. The No. 1 specimen (volume and moisture change specimen) shall be weighed and measured and both specimens placed in the moist room. Free water shall be made available to the absorbent pads under the specimens to permit absorption of water by the specimens by capillarity.

(*b*) After 22 hr. in the moist room, both specimens shall be weighed and the No. 1 specimen measured. Specimen No. 2 (soil-cement loss specimen) shall then be given two firm strokes on all areas with a wire scratch brush to remove all material loosened during freezing and thawing. The specimen shall be again weighed after brushing. The moisture content of the material brushed from the specimen shall be determined directly, but if this is not possible, it may be assumed to be equal to the moisture content of the No. 1 specimen. The oven-dry (110 C., 230 F.) weight of material brushed from the specimen shall be calculated.

(*c*) The procedures described in Paragraphs (*a*) and (*b*) constitute one cycle (48 hr.) of freezing and thawing. The specimens shall then be replaced in the refrigerator and the procedure continued. The data collected will permit calculations of volume and moisture changes of specimen No. 1 and the soil-cement losses of specimen No. 2.

(*d*) The freezing and thawing of the No. 1 specimens shall be continued for 12 cycles or discontinued prior to 12 cycles should the measurements become inaccurate due to distortion or soil-cement loss of the specimen. The freezing and thawing of the No. 2 specimens shall be continued for 12 cycles, if possible.

Calculation

6. The volume and moisture changes and the soil-cement losses of the specimens shall be calculated as follows:

(*a*) The difference between the volume of specimen No. 1 at time of molding and subsequent volumes shall be calculated as a percentage of the original volume.

(*b*) The moisture content of specimen No. 1 at the time of molding and subsequent moisture contents shall be calculated as a percentage of the original oven-dry weight of the specimen.

(*c*) The soil-cement loss of specimen No. 2 shall be calculated as a percentage of the original oven-dry weight of the specimen.

Standard Specifications for

ASPHALT FOR USE IN CONSTRUCTING BUILT-UP ROOF COVERINGS[1]

A.S.T.M. Designation: D 312 – 44

ADOPTED, 1941; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 312; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphalt intended for use as hot-cement and mopping coat in the construction of built-up roof coverings for roofs surfaced in various manners, laid either over boards or concrete on various inclines.

Primer

2. The material used as a primer when this asphalt is used over concrete and gypsum roof slabs shall be asphalt primer conforming to the Standard Specifications for Primer for Use with Asphalt in Dampproofing and Waterproofing (A.S.T.M. Designation: D 41).[3]

Membrane Materials

3. The felts for use in constructing built-up roof coverings with this asphalt shall be of the type covered by any of the following specifications:

(*a*) Standard Specifications for Asphalt-Saturated Roofing Felt for Use in Waterproofing and in Constructing Built-Up Roofs (A.S.T.M. Designation: D 226),[3]

(*b*) Tentative Specifications for Asphalt-Saturated Asbestos Felts for Use in Waterproofing and in Constructing Built-Up Roofs (A.S.T.M. Designation: D 250),[3] and

(*c*) Tentative Specifications for Asphalt-Saturated and Coated Asbestos Felts for Use in Constructing Built-Up Roofs (A.S.T.M. Designation: D 655).[3]

Types

4. The asphalts covered by these specifications are as follows:

(*a*) Relatively susceptible asphalts with good adhesive and "self-healing" properties for use in slag or gravel surfaced roofing on inclines up to 3 in. per ft.,

(*b*) Somewhat less susceptible asphalts for roofing laid on inclines up to 3 in. per ft. which are not surfaced with slag or gravel, and

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1929 to 1941, being revised in 1935, 1937, and 1939.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*c*) Relatively nonsusceptible asphalts for use on inclines between 3 and 6 in. per ft.

Properties

5. The asphalt shall be homogeneous and free from water. It shall conform to the requirements prescribed in Table I.

TABLE I.—REQUIREMENTS FOR ASPHALT FOR CONSTRUCTING BUILT-UP ROOF COVERINGS.

	Type of Roofing					
	Mineral Surfaced Flat		Unsurfaced Flat		Unsurfaced Steep	
	Min.	Max.	Min.	Max.	Min.	Max.
For use on decks having inclines:						
Over boards, in. per ft.	....	3	....	3	3	6
Over concrete, in. per ft.:

Ash, per cent:						
Filled or native asphalt	7.5	35	7.5	35	7.5	35
Unfilled asphalt	....	1	....	1	....	
Coarse particles retained on No. 200 (74-micron) sieve as percentage of matter insoluble in carbon disulfide, per cent	....	12	....	12	....	12

Sampling and Methods of Testing

6. The asphalt shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140).[3]

(*b*) *Softening Point.*—Standard Method of Test for Softening Point of Bituminous Materials (Ring-and-Ball Method) (A.S.T.M. Designation: D 36).[3]

(*c*) *Flash Point.*—Standard Method of Test for Flash and Fire Points by Means of Open Cup (A.S.T.M. Designation: D 92).[3]

(*d*) *Penetration.*—Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5).[3]

(*e*) *Ductility.*—Standard Method of Test for Ductility of Bituminous Materials (A.S.T.M. Designation: D 113).[3]

(*f*) *Loss on Heating.*—Tentative Method of Test for Loss on Heating of Oil and Asphaltic Compounds (A.S.T.M. Designation: D 6).[3]

(*g*) *Soluble in Carbon Disulfide.*—Standard Method of Test for Determination of Bitumen (A.S.T.M. Designation: D 4).[3]

(*h*) *Bitumen Soluble in Carbon Tetrachloride.*—Standard Method of Test for Proportion of Bitumen Soluble in Carbon Tetrachloride (A.S.T.M. Designation: D 165).[3]

(*i*) *Ash.*—Standard Methods of Laboratory Sampling and Analysis of Coal and Coke (A.S.T.M. Designation: D 271).[4]

(*j*) *Coarse Particles.*—Standard Method of Test for Coarse Particles in Mixtures of Asphalt and Mineral Matter (A.S.T.M. Designation: D 313).[3]

[4] 1944 Book of A.S.T.M. Standards, Part III.

Standard Specifications for

COAL-TAR PITCH FOR ROOFING, DAMPPROOFING, AND WATERPROOFING[1]

A.S.T.M. Designation: D 450 - 41

ADOPTED, 1941.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation D 450; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover coal-tar pitch suitable for use as a mopping coat in the construction of built-up roofs surfaced with slag or gravel, as a mopping coat in dampproofing, or as a plying or mopping cement in the construction of a membrane system of waterproofing.

Primer

2. The material used as a primer shall be creosote conforming to the Standard Specifications for Creosote for Priming Coat with Coal-Tar Pitch in Dampproofing and Waterproofing (A.S.T.M. Designation: D 43) of the American Society for Testing Materials.[3]

Membrane Materials

3. (*a*) For the construction of built-up roofs, felts conforming to the Standard Specifications for Coal-Tar Saturated Roofing Felt for Use in Waterproofing and in Constructing Built-Up Roofs (A.S.T.M. Designation: D 227) of the American Society for Testing Materials[3] shall be used.

(*b*) For the construction of a membrane system of waterproofing, any or all of the following felts, fabrics, or burlap conforming to the specifications of the American Society for Testing Materials may be used alone or in various combinations:

Felt.—Standard Specifications for Coal-Tar Saturated Roofing Felt for Use in Waterproofing and in Constructing Built-Up Roofs (A.S.T.M. Designation: D 227).[3]

Cotton Fabrics.—Standard Specifications for Woven Cotton Fabrics Saturated with Bituminous Substances for Use in Waterproofing (A.S.T.M. Designation: D 173),[3] coal-tar saturant.

Types

4. The coal-tar pitches covered by these specifications are of two types, as follows:

Type A.—Coal-tar pitch for use as a

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1937 to 1941, being revised in 1938.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

mopping coat in the construction of built-up roofs surfaced with slag or gravel on inclines not exceeding 3 in. per ft. where nailing is employed, and not exceeding 1 in. per ft. where nailing is omitted.

Coal-tar pitch for use as a mopping coat in dampproofing or as a plying cement in the construction of a membrane system of waterproofing above ground level when not exposed to temperatures exceeding 125 F. (52 C.).

specifications shall be determined in accordance with the following methods of the American Society for Testing Materials:

(*a*) *Sampling.*—Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140).[3]

(*b*) *Water.*—Standard Method of Test for Water in Petroleum Products and Other Bituminous Materials (A.S.T.M. Designation: D 95).[3]

(*c*) *Specific Gravity.*—Standard Method

TABLE I.—REQUIREMENTS FOR COAL-TAR PITCH FOR ROOFING, DAMPPROOFING, AND WATERPROOFING.

	Min.	Max.
Water, per cent	....	0
Specific gravity, 25/25 C. (77/77 F.)	1.22	1.34
Softening point (cube-in-water method):		
Type A	140 F. (60 C.)	155 F. (68 C.)
Type B	120 F. (49 C.)	140 F. (60 C.)
Flash point (Cleveland open cup)	248 F. (120 C.)	....
Distillation test:		
Total distillate by weight 32 to 572 F. (0 to 300 C.), per cent	....	10
Residue by weight, per cent	90	....
Specific gravity, 100/60 F. (38/15.5 C.), of total distillate to 572 F. (300 C.)	1.03	....
Softening point (cube-in-water method) of residue from distillation to 572 F. (300 C.)	....	175 F. (79 C.)
Ductility at 25 C. (77 F.), (5 cm. per min), cm.	50	....
Total bitumen soluble in carbon disulfide, per cent	72	83
Ash, per cent	....	0.5

NOTE.—The usual range for softening point of roofing pitch shall be 140 to 150 F. In hot summer weather a softening point range of 145 to 155 F. will be permitted.

NOTE.—This type of coal-tar pitch is suitable for railroad bridges, tanks, retaining walls, culverts, dams, conduits, etc.

Type B.—Coal-tar pitch for use as a mopping coat in dampproofing or as a plying cement in the construction of a membrane system of waterproofing below ground level under uniformly moderate temperature conditions both during the process of installation and during service.

Properties

5. The coal-tar pitch shall be homogenous and shall conform to the requirements prescribed in Table I.

Methods of Sampling and Testing

6. The coal-tar pitch shall be sampled and the properties enumerated in these

of Test for Specific Gravity of Road Oils, Road Tars, Asphalt Cements, and Soft Tar Pitches (A.S.T.M. Designation: D 70).[3]

(*d*) *Softening Point.*—Standard Method of Test for Softening Point of Tar Products (Cube-in-Water Method) (A.S.T.M. Designation: D 61).[2]

(*e*) *Flash Point.*—Standard Method of Test for Flash and Fire Points by Means of Open Cup (A.S.T.M. Designation: D 92).[3]

(*f*) *Distillation.*—Standard Method of Test for Distillation of Tar Products Suitable for Road Treatment (A.S.T.M. Designation: D 20).[3]

[4] 1944 Book of A.S.T.M. Standards, Part III.

AMERICAN ASSOCIATION STATE
HIGHWAY OFFICIALS STANDARD
A.A.S.H.O. NO.: M 116-42

Standard Specifications for

PRIMER FOR USE WITH ASPHALT IN DAMPPROOFING AND WATERPROOFING[1]

A.S.T.M. Designation: D 41 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 41; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphaltic primer for use, when specified, with asphalt in dampproofing and waterproofing below or above ground level, for application to concrete and masonry surfaces.

Properties

2. (*a*) The primer shall be free from water and shall conform to the following requirements:

Furol viscosity at 25 C. (77 F.)...25 to 150 sec.
Distillation, per cent by volume:
Up to 225 C. (437 F.).....not less than 35
Up to 360 C. (680 F.).....not more than 65

(*b*) The residue obtained from the distillation up to 360 C. (680 F.) shall conform to the following requirements:

Penetration at 25 C. (77 F.), 100 g., 5 sec.....20 to 50
Matter soluble in carbon disulfide....not less than 99 per cent

Sampling

3. (*a*) From each shipment or fraction thereof representing primer of the same kind, a number of packages shall be selected at random equivalent to the cube root of the total number of packages in the lot. If the cube root as calculated proves to be a fractional number, it shall be expressed as the next higher whole number. For convenience, the following table is given, showing the number of samples to be selected for shipments of various sizes:

Packages in Shipment	Packages Selected
2 to 8	2
9 to 27	3
28 to 64	4
65 to 125	5
126 to 216	6
217 to 343	7
344 to 512	8
513 to 729	9
730 to 1000	10
1001 to 1331	11

(*b*) By means of a paddle, the contents of each package selected shall be thor-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1917 to 1925, being revised in 1922 and 1925. They were adopted in 1925, published as standard from 1925 to 1936, being revised in 1926, but were withdrawn and republished as tentative from 1936 to 1941, being revised in 1939.

oughly stirred so as to bring all portions thereof into uniform distribution. With an appropriate sampler, not less than 1 pt. of the primer shall be immediately drawn from the center of each package, and transferred to a clean receptacle of suitable size, which in turn shall be kept tightly covered, prior and immediately after the samples are being introduced. After all the pint samples have been added, the contents of the container shall be thoroughly agitated, whereupon 1 qt. of the mixture shall immediately be transferred to a clean quart can provided with a tightly fitting screw cap, which shall be immediately fastened in place. This sample shall be considered as representative of the shipment and shall be transmitted to the laboratory for examination, bearing a suitable tag or other means of identification.

Methods of Testing

4. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Furol Viscosity.* — Standard Method of Test for Viscosity by Means of the Saybolt Viscosimeter (A.S.T.M. Designation: D 88).[3]

(*b*) *Distillation.*—Standard Method of Test for Distillation of Cut-Back Asphaltic Products (A.S.T.M. Designation: D 402).[3]

(*c*) *Penetration.*—Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5).[3]

(*d*) *Bitumen Soluble in Carbon Disulfide.*—Standard Method of Test for Determination of Bitumen (A.S.T.M. Designation: D 4).[3]

---

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

CREOSOTE FOR PRIMING COAT WITH COAL-TAR PITCH IN DAMPPROOFING AND WATERPROOFING[1]

A.S.T.M. Designation: D 43 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 43; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover creosote primer for use, when specified, with coal-tar pitch in dampproofing and waterproofing below or above ground level, for application to concrete and masonry surfaces.

Properties[2a]

2. Creosote primer shall be a distillate of coal-gas tar or coke-oven tar and shall conform to the following requirements:

Water	not more than 1 per cent
Consistency at 5 C. (41 F.)	entirely fluid and crystal free[a]
Specific gravity, 38/15.5 C. (100/60 F.)	not less than 1.06
Matter insoluble in benzol	not more than 0.5 per cent
Distillation, based on water-free oil:	
Up to 210 C.	not more than 1 per cent
Up to 235 C.	not more than 10 per cent
Up to 355 C.	not less than 65 per cent
Coke residue	not more than 2 per cent

[a] The creosote shall be rated as crystal free if no crystals are formed when 100 ml. of the sample is maintained at a temperature of 5 C. (41 F.) for 3 hr., in a 125 ml. Erlenmeyer flask, with occasional stirring.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1917 to 1925, being revised in 1922. They were adopted in 1925, published as standard from 1925 to 1936, but were withdrawn and republished as tentative from 1936 to 1941, being revised in 1937.

[2a] Editorially revised in 1942.

Sampling

3. (*a*) From each shipment or fraction thereof representing creosote of the same kind, a number of packages shall be selected at random equivalent to the cube root of the total number of packages in the lot. If the cube root as calculated proves to be a fractional number, it shall be expressed as the next higher whole number. For convenience, the following table is given, showing the number of samples to be selected for shipments of various sizes:

Packages in Shipment	Number of Packages Selected
2 to 8	2
9 to 27	3
28 to 64	4
65 to 125	5
126 to 216	6
217 to 343	7
344 to 512	8
513 to 729	9
730 to 1000	10
1001 to 1331	11

(*b*) By means of a paddle, the contents of each package selected shall be thoroughly stirred so as to bring all portions thereof into uniform distribution. With

an appropriate sampler, not less than 1 pt. of the creosote shall be immediately drawn from the center of each package and transferred to a clean receptacle of suitable size, which in turn shall be kept tightly covered, prior and immediately after the samples are being introduced. After all the pint samples have been added, the contents of the container shall be thoroughly agitated, whereupon 1 qt. of the mixture shall immediately be transferred to a clean quart can provided with a tightly fitting screw cap, which shall be immediately fastened in place. This sample shall be considered as representative of the shipment and shall be transmitted to the laboratory for examination, bearing a suitable tag or other means of identification.

(*c*) Creosote primer in large shipments shall be sampled in accordance with the Standard Methods of Sampling and Testing Creosote (A.S.T.M. Designation: D 38) of the American Society for Testing Materials.[3]

Methods of Testing

4. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Water.*—Standard Method of Test for Water in Creosote (A.S.T.M. Designation: D 370).[3]

(*b*) *Specific Gravity.* — Standard Method of Test for Specific Gravity of Creosote (A.S.T.M. Designation D 368).[3]

(*c*) *Matter Insoluble in Benzol.*—Standard Methods of Test for Insoluble Matter in Creosote (A.S.T.M. Designation: D 367).[3]

(*d*) *Distillation.*—Standard Method of Test for Distillation of Creosote (A.S.T.M. Designation: D 246).[3]

(*e*) *Coke Residue.*—Standard Method of Test for Coke Residue of Creosote (A.S.T.M. Designation: D 168).[3]

(*f*) *Volume and Specific Gravity Correction.*—Standard Volume and Specific Gravity Correction Tables for Creosote and Coal Tar (A.S.T.M. Designation: D 347).[3]

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Method of Test for

STEAM DISTILLATION OF BITUMINOUS PROTECTIVE COATINGS[1]

A.S.T.M. Designation: D 255 - 28

ADOPTED, 1928.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 255; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This is a general method for the separation and recovery of the solvent and the base in bituminous mixtures. The bituminous mixture is distilled in a current of steam, the solvent condensed and separated from the water.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Steam Generator.*—A steam generator made of either metal or glass, with a capacity of from 2 to 4 liters, suitable for continued use in the production of steam. If of glass, it shall be fitted with two outlets with suitable connections for rubber tubing. In the case of a metal generator, a large opening for filling and a water gage shall be additional parts of the apparatus. The generator shall be supplied with suitable pinch cocks or valves so that steam may be blown off to the atmosphere until the test is ready.

(*b*) *Bath.*—A bath made of metal and having sufficient capacity to permit immersion of the distilling flask to a depth of not less than 10 cm.

(*c*) *Source of Heat.*—A gas burner, electric hot plate, or equivalent source of heat for the bath.

(*d*) *Distilling Flask.*—A 100-ml. distilling flask with a short ring neck and round-bottom. It shall be fitted with a three-hole rubber stopper, a steam delivery tube which will reach to within $\frac{1}{2}$ in. (12.7 mm.) of the bottom of the flask and project from the top to a convenient distance for connection to the generator, a vapor outlet tube which extends from beneath the rubber stopper to a point sufficiently above the distilling flask to permit convenient connection to the condenser, and a thermometer. The steam tubing should be not less than 2 nor more than 4 mm. in internal diameter and the vapor outlet tube should be not less than 5 mm. in internal diameter.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1926 to 1928. Editorially revised and rearranged in 1939.

(*e*) *Condenser.*—A condenser made of No. 20 Stubbs gage seamless brass tubing $\frac{9}{16}$ in. (14.29 mm.) in outside diameter and 22 in. (55.88 cm.) in length. It shall be set at an angle of 75 deg. from the perpendicular and be surrounded with a cooling bath 15 in. (38.1 cm.) in length, approximately 4 in. (10.16 cm.) in width by 6 in. (15.24 cm.) in height. The lower end of the condenser tube shall be cut off at an acute angle, and curved downward for a length of 3 in. (7.62 cm.) and slightly backward so as to insure contact with the wall of the graduate at a point 1 to $1\frac{1}{4}$ in. (2.54 to 3.18 cm.) below the top of the graduate when it is in position to receive the distillate.

(*f*) *Separatory Funnel.*—A separatory funnel as shown in Fig. 1, having a capacity of not less than 500 ml.

(*g*) *Thermometer.*—An A.S.T.M. Low Distillation Thermometer, total immersion, graduated in either Centigrade or Fahrenheit degrees as specified, having a range of 0 to 300 C. or 30 to 580 F. and conforming to the requirements for this thermometer as prescribed in the Standard Specifications for A.S.T.M. Thermometers (A.S.T.M. Designation: E 1) of the American Society for Testing Materials.[3]

(*h*) *Accessories.*—Accessories consisting of suitable ring stands for supporting the steam generator, distilling flask, bath for distilling flask, and separatory funnel.

Procedure

3. The apparatus shall be assembled as shown in Fig. 1. The steam generator shall be filled with water and heat applied. The bath shall be filled with a high-flash-point oil and raised to approximately 140 C. (284 F.). A 500-ml. sample shall be weighed into the round-bottom flask. The steam generator shall be connected to the steam delivery tube, the end of which shall be within $\frac{1}{2}$ in. of the bottom of the distilling flask. The outlet from the distilling flask shall be connected to the condenser and the separatory funnel placed in position at the outlet of the condenser to receive the distillate. The end of the bulb of the thermometer in the steam distilling flask shall be placed within $\frac{1}{2}$ in. (12.7 mm.) of the bottom of the distilling flask. When the temperature of the

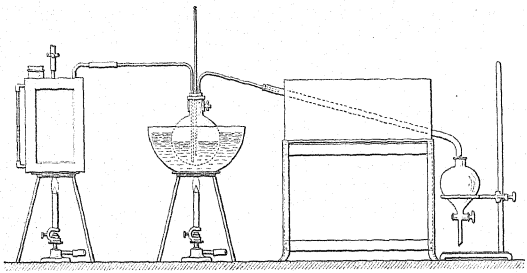

FIG. 1.—Assembly of Apparatus.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

sample in the distilling flask reaches 130 C. the outlet of the steam generator shall be closed, thus forcing the steam to pass through the sample. The flow of steam shall be adjusted so that the distillate is collected at the rate of approximately 6 to 10 ml. per min. The distillation shall be stopped when 100 ml. of the distillate contains not more than 0.5 ml. of solvent as determined by measuring the amount of oil in 100 ml. of distillate. When the distillation is finished, the water shall be separated from the distillate and the distillate measured and retained for further tests if required by the specifications. In some cases, the distillate does not separate readily from the water; this separation can be facilitated by the addition of sodium chloride which will result in a sufficient difference in gravity to produce a clear separation of the two layers.

Report

4. The results shall be reported as a percentage by weight or by volume as required by the specifications, based on the weight of the sample taken.

Standard Methods of

TESTING FILMS DEPOSITED FROM BITUMINOUS EMULSIONS[1]

A.S.T.M. Designation: D 466 – 42

ADOPTED, 1942.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 466; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

RESISTANCE TO FLOW UNDER HEAT (SLIDE TEST)

Scope

1. The slide test is applicable to bituminous emulsions or reinforced emulsions intended to be applied at the rate of not less than 3 gal. per 100 sq. ft. and on substantially vertical surfaces.

Apparatus

2. The apparatus shall consist of the following:

(*a*) *Brass Mask.*—A brass mask approximately $\frac{7}{64}$ in. in thickness with a rectangular opening 4 by 4 in.

(*b*) *Tiles.*—Unglazed ceramic tiles[3] white, nonvitreous, dust pressed body with an absorption range of 15 to 18 per cent (determined in accordance with the Standard Methods of Sampling and Testing Structural Clay Tile (A.S.T.M. Designation: C 112) of the American Society for Testing Materials[4]) approximately 6 by 6 in. by $\frac{3}{8}$ to $\frac{1}{2}$ in. in thickness, or of sufficient size to accommodate the opening of the mask.

Procedure

3. (*a*) *Preparation of Tile.*—The tile shall be immersed in distilled water for at least 10 min. and the excess water removed immediately before application of the emulsion.

(*b*) *Preparation of Film.*—The sample of emulsion shall be thoroughly stirred. The brass mask shall then be applied to the smooth face of the tile and the emulsion spread over the area of the tile within the mask opening. The excess emulsion shall be doctored off with a flat scraper so that the film after drying shall be not less than 0.04 in. (1 mm.) in thickness.

(*c*) *Drying.*—The coated tile shall then be dried to constant weight in an atmosphere of low relative humidity at room temperature and weighed every 24 hr. A film shall be considered dry when the loss in two successive 24-hr. weighings is not greater than 0.1 g.

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these methods were published as tentative from 1937 to 1942, being revised in 1938 and 1942.

[3] Suitable unglazed tile can be obtained from the Robertson Art Tile Co., Morrisville, Pa., and from Gladding-McBean and Co., Los Angeles, Calif.

[4] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

NOTE.—Drying may be hastened by placing the specimen in a current of air from an electric fan.

(*d*) *Testing.*—After drying and removing the brass mask, the coated tile shall be suspended vertically in the center of an air oven maintained at 176 ± 5 F. (80 ± 3 C.). The internal dimensions of the oven shall be not less than 12 by 12 by 12 in. An electrically heated oven is recommended. A thermometer shall be inserted in the oven to such depth that its bulb will be in line with the center of the specimen. The tile shall be maintained at the prescribed temperature for exactly 2 hr. Any sliding shall be determined by a reference line placed originally on the tile, coincident with the lower edge of the dried film.

RESISTANCE TO WATER ACTION

Scope

4. The purpose of this test is to determine the ability of the dried film to retain its adhesion and to resist re-emulsification after immersion in water.

Procedure

5. (*a*) *Preparation of Film.*—The film to be tested shall be prepared as described in Sections 2 and 3.

(*b*) *Testing.*—After drying, a ring approximately 2 in. in diameter and 1 in. in height shall be pressed into the surface of the coated tile. The ring shall be filled with tap water and the test specimen maintained at room temperature between 70 to 90 F. (21 to 32 C.). After 24 hr. the character of the bituminous film shall be noted by cutting and attempting to lift a portion of the submerged film with a knife or teasing needle. Adhesion or bond shall be determined by making intersecting cuts with the knife or needle and lifting the cut film at the point of intersection. Re-emulsification is indicated if the water becomes darkened by rubbing the submerged surface of the uncut film lightly with a rubber policeman.

STANDARD VOLUME CORRECTION TABLE FOR TAR AND COAL-TAR PITCH[1]

A.S.T.M. Designation: D 633 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 633; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

This table has been prepared by the National Bureau of Standards to meet a demand from the tar industry for a short and convenient table for reducing volumes of road tar and coal-tar pitch to the basis of 60 F., when extreme accuracy is not required. The table shows the volume occupied at 60 F. by a quantity of material occupying unit volume at the indicated temperature.

The groups and coefficients of expansion for the several subdivisions of the present table are as follows:

Group Number	Coefficient of Expansion, per Deg. Fahr. at 60 F.	Material
000	0.00026	Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing[a] Coal-Tar Pitch for Stone Block Filler[b]
00	0.00030	Tar,[c] Grades RT-5, RT-6, RT-7, RT-8, RT-9, RT-10, RT-11, RT-12, RT.C.B.-5, and RT.C.B.-6
0	0.00035	Tar,[c] Grades RT-1, RT-2, RT-3, and RT-4

[a] Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450) of the American Society for Testing Materials.[3]

[b] Standard Specifications for Coal-Tar Pitch for Stone Block Filler (A.S.T.M. Designation: D 112) of the American Society for Testing Materials.[3]

[c] Tentative Specifications for Tar (A.S.T.M. Designation: D 490) of the American Society for Testing Materials.[3]

NOTE: *Example.*—The values given in the table are in the form of multipliers; that is, the volume at the indicated temperature for each group, multiplied by the corresponding factor in the table, equals the volume at 60 F. For example, if the volume at 238 F. of coal-tar roofing pitch (Group 000) equals 7900 gal., then the volume at 60 F. equals 7900 × 0.9558 or 7551 gal.

[1] Under the standardization procedure of the Society, this standard is under the joint jurisdiction of the A.S.T.M. Committee D-4 on Road and Paving Materials and Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, this table was published as tentative from 1941 to 1944.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

ASPHALT MASTIC FOR USE IN WATERPROOFING[1]

ASPHALT CEMENT, MINERAL FILLER, MINERAL AGGREGATE

A.S.T.M. Designation: D 491 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 491; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover materials for asphalt mastic suitable for use in waterproofing, consisting of asphalt cement, mineral filler, and mineral aggregate.

(*b*) The asphalt mastic covered by these specifications is suitable for waterproofing the floors of buildings and bridges, for reservoirs, waterways, subways, and similar structures. It is not intended for use as a pavement for either foot or vehicular traffic.

Character of Mastic

2. (*a*) The asphalt mastic shall consist of a mixture of asphalt cement, mineral filler, and mineral aggregate which, at a temperature of approximately 400 F. (205 C.), shall be sufficiently plastic to be poured into place and compressed with a wooden trowel or by other suitable means into a compact, watertight sheet of the thickness desired.

(*b*) The raw materials for the asphalt mastic are expected to be mixed on the site of the work, in either suitable mechanically operated heaters and mixers, or by manual stirring in open pans or kettles; or the asphalt cement and mineral matter may be mixed elsewhere and brought to the site of the work in the form of cakes (weighing approximately 75 lb. each) and there combined by the method described for raw materials with mineral aggregate and asphalt cement as may be necessary to comply with the requirements of Section 4. The mixture so prepared shall be applied to the work, or preformed for application to the work, while it is sufficiently hot to be manipulated with hand tools or by other equivalent means.

Properties of Asphalt Cement

3. The asphalt cement used in the asphalt mastic shall conform to the following requirements:

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1938 to 1941, being revised in 1939.

These specifications comprise a consolidation of and replace the former Standard Specifications for Asphalt Mastic for Use in Waterproofing (D 169 - 25), Acid-Resisting Asphalt Mastic (D 223 - 30), and Tentative Specifications for Asphalt Mastic for Use in Waterproofing (Asphalt Cement, Mineral Filler, Mineral Aggregate) (D 491 - 38 T), which standards were accordingly discontinued in 1939.

	Minimum	Maximum
Softening point (ring-and-ball method)	130 F. (54 C.)	150 F. (65 C.)
Penetration at 77 F. (25 C.), 100 g., 5 sec.	20	40
Ductility at 77 F. (25 C.) (5 cm. per min.), cm.	15	..
Loss on heating at 325 F. (163 C., 50 g., 5 hr., per cent	..	2
Penetration of residue at 77 F. (25 C.), per cent of original	60	..
Solubility in carbon disulfide:		
Filled or native asphalt cement, per cent	60	..
Unfilled asphalt cement, per cent	99	..
Bitumen soluble in carbon tetrachloride, per cent	99	..
Ash:		
Filled or native asphalt cement, per cent	7.5	35
Unfilled asphalt cement, per cent	..	1

Properties of Asphalt Mastic

4. (*a*) The asphalt mastic shall conform to the following requirements by weight (or as prescribed by the purchaser within these limitations) as determined by laboratory analysis:

	Minimum	Maximum
Bituminous matter soluble in pure benzol, per cent	10	12
Mineral filler insoluble in benzol, passing a No. 200 (74-micron) sieve, per cent	10	25
Mineral aggregate:		
Passing a No. 40 (420-micron) and retained on a No. 200 (74-micron) sieve, per cent	10	30
Passing a No. 10 (2000-micron) and retained on a No. 40 (420-micron) sieve, per cent	10	35
Passing a No. 4 (4760-micron) and retained on a No. 10 (2000-micron) sieve, per cent	5	25
Passing a ½-in. and retained on a No. 4 (4760-micron) sieve, per cent	5	25

(*b*) The portion of asphalt mastic which is soluble in pure benzol, after extraction and recovery, shall conform to the following requirements:

	Minimum	Maximum
Softening point (ring-and-ball method)	122 F. (50 C.)	158 F. (70 C.)
Penetration at 77 F. (25 C.), 100 g., 5 sec.	15	40
Ductility at 77 F. (25 C.) (5 cm. per min.), cm	15	..

(*c*) That portion of asphalt mastic, when designated as acid resisting, which is insoluble in benzol shall conform to the following requirement:

Matter soluble in diluted HCl....not more than 5 per cent

Methods of Testing

5. The properties enumerated in these specifications shall be determined in accordance with the following methods of test of the American Society for Testing Materials:

(*a*) *Asphalt Mastic.*—Standard Methods of Testing Bituminous Mastics, Grouts, and Like Mixtures (A.S.T.M. Designation: D 147).[3]

(*b*) *Softening Point.*—Standard Method of Test for Softening Point of Bituminous Materials (Ring-and-Ball Method) (A.S.T.M. Designation: D 36).[3]

(*c*) *Penetration.*—Standard Method of Test for Penetration of Bituminous Materials (A.S.T.M. Designation: D 5).[3]

(*d*) *Ductility.*—Standard Method of Test for Ductility of Bituminous Materials (A.S.T.M. Designation: D 113).[3]

(*e*) *Loss on Heating.*—Tentative Method of Test for Loss on Heating of Oil and Asphaltic Compounds (A.S.T.M. Designation: D 6).[3]

(*f*) *Sieve Analysis.*—Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136).[3]

(*g*) *Recovery and Preparation of Matter Soluble in Benzol.*—Until an A.S.T.M. method is available, recovery and preparation for test of the bituminous matter soluble in pure benzol shall be made according to the "Method and Apparatus for the Recovery of Asphalt," as described in the paper by Gene Abson.[4]

Standard Specifications for

BITUMINOUS GROUT FOR USE IN WATERPROOFING ABOVE GROUND LEVEL[1]

A.S.T.M. Designation: D 170 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 170; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover the materials for bituminous grout suitable for use in waterproofing above ground level, either as a protective covering of membrane systems of waterproofing, or for bedding brick or filling the joints or flooding the surface of a brick protective covering.

(*b*) The grade of bituminous grout covered by these specifications is suitable for waterproofing railroad bridges, culverts, subways, etc.

Properties

2. The bituminous grout shall consist of a mixture of substantially 45 parts by weight of bituminous binder and 55 parts by weight of mineral aggregate as coarse as sand, which mixture becomes sufficiently fluid when heated to approximately 205 C. (400 F.), to flow without mechanical manipulation, and which on cooling congeals to a compact mass.

Bituminous Binder

3. The bituminous binder shall consist of either asphalt or coal-tar pitch as follows:

(*a*) *Asphalt.*—The asphalt shall conform to the requirements for type B asphalt as prescribed in the Tentative Specifications for Asphalt for Dampproofing and Waterproofing (A.S.T.M. Designation: D 449) of the American Society for Testing Materials.[3]

(*b*) *Coal-Tar Pitch.*—The coal-tar pitch shall conform to the requirements for type A pitch as prescribed in the Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450) of the American Society for Testing Materials.[3]

Mineral Aggregate

4. The mineral aggregate shall con-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1923 to 1925, being revised in 1924. They were adopted in 1925, published as standard from 1925 to 1939, but withdrawn and republished as tentative from 1939 to 1941.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

sist of siliceous sand all of which passes a No. 20 (840-micron) sieve, and not more than 5 per cent of which passes a No. 200 (74-micron) sieve.

Methods of Testing

5. The properties enumerated in Sections 2 and 4 shall be determined in accordance with the Standard Methods of Testing Bituminous Mastics, Grouts, and Like Mixtures (A.S.T.M. Designation: D 147) of the American Society for Testing Materials.[3]

Standard Specifications for

BITUMINOUS GROUT FOR USE IN WATERPROOFING BELOW GROUND LEVEL[1]

A.S.T.M. Designation: D 171 - 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 171; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover the materials for bituminous grout suitable for use in waterproofing below ground level, either as a protective covering of membrane systems of waterproofing, or for bedding brick or filling the joints or flooding the surface of a brick protective covering.

(*b*) The grade of bituminous grout covered by these specifications is suitable for waterproofing tunnels, subways, etc.

Properties

2. The bituminous grout shall consist of a mixture of substantially 45 parts by weight of bituminous binder and 55 parts by weight of mineral aggregate as coarse as sand, which mixture becomes sufficiently fluid when heated to approximately 149 C. (300 F.), to flow without mechanical manipulation, and which on cooling congeals to a compact mass.

Bituminous Binder

3. The bituminous binder shall consist of either asphalt or coal-tar pitch as follows:

(*a*) *Asphalt.*—The asphalt shall conform to the requirements for type A asphalt as prescribed in the Tentative Specifications for Asphalt for Dampproofing and Waterproofing (A.S.T.M. Designation: D 449) of the American Society for Testing Materials.[3]

(*b*) *Coal-Tar Pitch.*—The coal-tar pitch shall conform to the requirements for type B pitch as prescribed in the Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450) of the American Society for Testing Materials.[3]

Mineral Aggregate

4. The mineral aggregate shall con-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1923 to 1925, being revised in 1924. They were adopted in 1925, published as standard from 1925 to 1939, but withdrawn and republished as tentative from 1939 to 1941.

sist of siliceous sand all of which passes a No. 20 (840-micron) sieve, and not more than 5 per cent of which passes a No. 200 (74-micron) sieve.

Methods of Testing

5. The properties enumerated in Sections 2 and 4 shall be determined in accordance with the Standard Methods of Testing Bituminous Mastics, Grouts, and Like Mixtures (A.S.T.M. Designation: D 147) of the American Society for Testing Materials.[3]

Standard Specifications for

ASPHALT-SATURATED ROOFING FELT FOR USE IN WATERPROOFING AND IN CONSTRUCTING BUILT-UP ROOFS[1]

A.S.T.M. Designation: D 226 – 44

ADOPTED, 1942; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 226; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphalt-saturated felts, either 36 or 32 in. in width, composed of roofing felt saturated, but not coated, with asphalt for use in the membrane system of waterproofing and in the construction of built-up roofs.

Types

2. Asphalt-saturated felts covered by these specifications are of two types: namely,

15-lb. type
30-lb. type

Mopping Materials

3. (*a*) For the construction of built-up roofs, mopping asphalts conforming to the Standard Specifications for Asphalt for Use in Constructing Built-Up Roof Coverings (A.S.T.M. Designation: D 312)[3] shall be used.

(*b*) For the construction of a membrane system of waterproofing, types A, B, or C mopping asphalt conforming to the Tentative Specifications for Asphalt for Dampproofing and Waterproofing (A.S.T.M. Designation: D 449)[3] shall be used depending upon service conditions as described in Section 4 of Specifications D 449.

Manufacture

4. In the process of manufacture, a single thickness of dry roofing felt shall be saturated with an asphaltic saturant.

Character of Felt

5. The felt shall be a roofing felt produced by "felting" vegetable or animal fibers or mixtures thereof. The surface of the felt shall be uniformly smooth.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1925 to 1927, being revised in 1926 and 1927. They were adopted in 1927, published as standard from 1927 to 1938, but withdrawn, revised, and republished as tentative in 1938, being revised in 1941 and 1942.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Upon splitting or tearing on the bias, the felt shall appear reasonably free from lumps of underbeaten stock (that is, stock that has not been beaten or shredded into fiber in the process of manufacture) and particles of foreign substances (that is, fragments of stone, metal, leather, rubber, etc.).

Character of Saturant

6. The bitumen of the saturant shall be composed of asphaltic materials.

Character of Saturated Felt

7. The felt shall be thoroughly and uniformly saturated, and shall show no unsaturated spots at any point upon cutting 2-in. strips at random across the entire sheet and splitting them open for their full length.

Surface Finish

8. The surface of the felt shall not be coated or covered with talc or other substance that would tend to interfere with the adhesion between the felt and the plying cement.

Physical Properties

9. The fabricated product shall conform to the following requirements:

	15-lb. Type	30-lb. Type
Width of roll	either 36 or 32 in. as may be specified, ±¼ in.	
Area of roll, min., sq. ft.	432	216
Minimum weight of saturated felt per 100 sq. ft. (exclusive of wrapping and packing material), lb.	14	28
Loss on heating at 105° C. (221 F.) for 5 hr., max., per cent		4
Pliability at 77 F. (25 C.): The 10 strips tested shall not crack when bent 90 deg. at a uniform speed over a rounded corner of	½ in. rad.	¾ in. rad.
Average breaking strength at 77 F. (25° C.):		
With fiber grain, min., lb.	30	40
Across fiber grain, min., lb.	15	20
Saturant in moisture-free felt, min., per cent by weight	140	150

Desaturated Felt

10. The desaturated moisture-free felt shall conform to the following requirements:

	15-lb. Type	30-lb. Type
Weight per 100 sq. ft., min., lb	5.2	10.0
Ash, max., per cent	10	10

Freedom from Defects

11. The finished material shall be free of visible external defects, such as holes, ragged or untrue edges, breaks, cracks, tears, protuberances, and indentations.

Pliability and Stickiness

12. The rolls shall not crack nor be so sticky as to cause tearing or material damage upon being unrolled at atmospheric temperatures above 50 F. (10 C.).

Packing

13. The rolls of saturated felt need not be wound on cores, but they shall be securely wrapped in a substantial grade of paper of the same width as the fabric. The wrapper shall completely encircle the roll and shall be pasted at the overlap in a manner that will prevent it shifting from position. The ends of the roll need not be covered. As an alternative, the rolls of saturated felt may either be tied with strings or simply pasted at the ends, as may be agreed upon by the purchaser and the seller. No roll shall contain more than two pieces, and there shall not be more than 3 per cent of rolls containing two pieces in any shipment.

Marking

14. Each roll shall be plainly marked with the manufacturer's name and

brand or as agreed upon by the purchaser and the seller, and shall bear a notation showing the type of saturant.

Sampling and Testing

15. The material shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the Tentative Methods of Testing Felted and Woven Fabrics Saturated with Bituminous Substances for Use in Waterproofing and Roofing (A.S.T.M. Designation: D 146).[3]

Inspection

16. Inspection of material shall be made as mutually agreed upon by the purchaser and the seller as part of the purchase contract.

Basis of Rejection

17. Failure to conform to any one of the requirements prescribed in these specifications shall constitute grounds for rejection. In case of rejection, the seller shall have the right to reinspect the rejected shipment and resubmit the lot after removal of those packages not conforming to the specified requirements.

Standard Specifications for

COAL-TAR SATURATED ROOFING FELT FOR USE IN WATERPROOFING AND IN CONSTRUCTING BUILT-UP ROOFS[1]

A.S.T.M. Designation: D 227 – 44

ADOPTED, 1927; REVISED, 1941, 1942, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 227; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover coal-tar saturated felt, either 36 or 32 in. in width, composed of roofing felt saturated, but not coated, with refined coal tar, for use in the membrane system of waterproofing and in the construction of built-up roofs.

Mopping Materials

2. (*a*) For the construction of built-up roofs on inclines not exceeding 3 in. per ft. where nailing is employed and not exceeding 1 in. per ft. where nailing is omitted, type A coal-tar pitch conforming to the Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450)[3] shall be used.

(*b*) For the construction of steep built-up roofs with inclines of 1 to 6 in. per horizontal foot where nailing is employed, the Tentative Specifications for Coal-Tar Pitch for Steep Built-Up Roofs (A.S.T.M. Designation: D 654)[3] may be used.

(*c*) For the construction of a membrane system of waterproofing, types A or B coal-tar pitch conforming to the Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450)[3] shall be used depending upon the conditions of service as described in Section 4 of Specifications D 450.

Manufacture

3. In the process of manufacture, a single thickness of dry roofing felt shall be saturated with a coal-tar saturant.

Character of Felt

4. The felt shall be a roofing felt produced by "felting" vegetable and animal fibers or mixtures thereof. The surface

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1925 to 1927, being revised in 1926 and 1927.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

of the felt shall be uniformly smooth. Upon splitting or tearing on the bias, the felt shall appear reasonably free from lumps of underbeaten stock (that is, stock that has not been beaten or shredded into fiber in the process of manufacture) and particles of foreign substances (that is, fragments of stone, metal, leather, rubber, etc.).

Character of Saturant

5. The saturant shall be composed of coal tar from which the highly volatile constituents have been removed.

Character of Saturated Felt

6. The felt shall be thoroughly and uniformly saturated and shall show no unsaturated spots at any point upon cutting 2-in. strips at random across the entire sheet and splitting them open for their full length.

Surface Finish

7. The surface of the felt shall not be coated or covered with talc or other substance that would tend to interfere with the adhesion between the felt and the plying cement.

Physical Properties

8. The fabricated product shall conform to the following requirements:

Width of roll	either 36 or 32 in., as may be specified, ± ¼ in.
Area of roll	432 sq. ft., min.
Weight of material per 100 sq. ft. exclusive of packing and wrapping	14 lb., min.
Moisture	2.5 per cent of the net weight, max.
Average breaking strength at 77 F. (25 C.):	
With fiber grain	30 lb., min.[a]
Across fiber grain	15 lb., min.[a]
Pliability at 77 F. (25 C.)	the 10 strips tested shall not crack when bent 90 deg. at a uniform speed over a rounded corner of ½-in. radius
Saturant in moisture-free felt	140 per cent by weight, min.

[a] If samples fail to conform to the requirements for breaking strength immediately after sampling, a retest shall be made upon test specimens which have been suspended in free air at laboratory temperature for 72 hr. Material shall be accepted or rejected upon the basis of this retest.

Desaturated Felt

9. The desaturated moisture-free felt shall conform to the following requirements:

Weight per 100 sq. ft., min., lb	5.2
Ash, max., per cent	10

Freedom from Defects

10. The finished material shall be free of visible external defects, such as holes, ragged or untrue edges, breaks, cracks, tears, protuberances, and indentations.

Pliability and Stickiness

11. The rolls shall not crack, nor be so sticky as to cause tearing or material damage upon being unrolled at atmospheric temperatures above 50 F. (10 C.).

Packing

12. The rolls of saturated felt need not be wound on cores, but they shall be securely wrapped in a substantial grade of paper of the same width as the fabric. The wrapper shall completely encircle the roll and shall be pasted at the overlap in a manner that will prevent it shifting from position. The ends of the roll need not be covered. As an alternative, the rolls of saturated felt may either be tied with strings or simply pasted at the ends, as may be agreed upon by the purchaser and the seller. No roll shall contain more than two pieces, and there shall not be more than 3 per cent of rolls containing two pieces in any shipment.

Marking

13. Each roll shall be plainly marked with the manufacturer's name and brand or as agreed by the purchaser and the seller, and shall bear a notation showing the type of saturant.

Sampling and Testing

14. The material shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the Tentative Methods of Testing Felted and Woven Fabrics Saturated with Bituminous Substances for Use in Waterproofing and Roofing (A.S.T.M. Designation: D 146).[3]

Inspection

15. Inspection of material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

Basis of Rejection

16. Failure to conform to any one of the requirements prescribed in these specifications shall constitute grounds for rejection. In case of rejection, the seller shall have the right to reinspect the rejected shipment and resubmit the lot after removal of those packages not conforming to the specified requirements.

Standard Specifications for WOVEN COTTON FABRICS SATURATED WITH BITUMINOUS SUBSTANCES FOR USE IN WATERPROOFING[1]

A.S.T.M. Designation: D 173 – 44

ADOPTED, 1942; REVISED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 173; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover bituminized cotton fabric, composed of woven cotton cloth waterproofed with either asphalt or coal-tar pitch, as specified by the purchaser, for use in the membrane system of waterproofing.

Mopping Materials

2. (*a*) For the construction of a membrane system of waterproofing with cotton fabric saturated with asphalt, types A, B, or C asphalt conforming to the Tentative Specifications for Asphalt for Dampproofing and Waterproofing (A.S.T.M. Designation: D 449)[3] shall be used depending upon the conditions of service as described in Section 4 of Specifications D 449.

(*b*) For the construction of a membrane system of waterproofing with woven cotton fabric saturated with coal-tar, coal-tar pitch conforming to the Standard Specifications for Coal-Tar Pitch for Roofing, Dampproofing, and Waterproofing (A.S.T.M. Designation: D 450)[3] shall be used.

Manufacture

3. In the process of manufacture, the dry cotton fabric shall be thoroughly and uniformly waterproofed with either an asphaltic or coal-tar pitch saturant, at a temperature and speed that will not injure the fabric. This shall be accomplished either by passing the fabric through the saturant or by spraying with saturant and then calendering it in the presence of heat, whereupon it shall be cooled and wound into rolls.

Character of Saturated Fabric

4. The meshes of the fabric shall not be completely closed or sealed by the process of saturation, but there shall be sufficient porosity maintained to allow

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard these specifications were published as tentative from 1923 to 1925, being revised in 1925. They were adopted in 1925, published as standard from 1925 to 1938, being revised in 1927, but withdrawn, revised and republished as tentative in 1938, being revised in 1939 and 1940.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

successive moppings of the plying cement to seep through.

Surface Finish

5. (*a*) The surface of the fabric shall not be coated or covered with talc or other substance that would tend to interfere with the adhesion between the fabric and the plying cement. The use of silica or wood flour will be permitted.

(*b*) The surface shall be uniformly smooth and free from irregularities, folds, or knots.

Selvage

8. If selvage is used, it shall measure not more than $\frac{1}{4}$ in.

Freedom from Defects

9. The finished material shall be free of visible external defects such as ragged or untrue edges, breaks, rents, or cracks.

Pliability and Stickiness

10. The roll shall be capable of being unrolled easily at atmospheric temperatures above 50 F. (10 C.) without sticking together in such a manner as to injure the fabric.

TABLE I.—PHYSICAL REQUIREMENTS FOR SATURATED COTTON FABRICS FOR WATERPROOFING.

	Min.	Max.
Width of roll	30 in.	38 in.
Gross weight per roll	35 lb.	80 lb.
Weight of wrapping material and mandrel per roll	.....	2.5 lb.
Average net weight per square yard	10 oz.	.....
Detached comminuted surfacing per 100 sq. ft.	.....	1 lb.
Moisture content based on net weight	.....	4 per cent
Average strength at 70 F. (21.1 C.) measured lengthwise of the roll (that is, in the direction of the warp)	50 lb.[a]	.....
Average strength at 70 F. (21.1 C.) measured crosswise of the roll (that is, in the direction of the filling)	50 lb.[a]	.....
Average loss on heating (exclusive of moisture) of asphalt-saturated fabrics	.....	4 per cent
Saturant in fabricated material	1.6 times the weight of the moisture-free fabric in the same area	.....
Pliability at 32 F. (0 C.)	No cracking of the fabricated bituminized fabric shall take place on bending over a ½-in. mandrel through an arc of 180 deg. in one direction and then through 360 deg. over the same mandrel in the opposite direction	

[a] The committee recognizes the advisability of including a requirement relative to the percentage elongation before rupture, but in the absence of any reliable method of test, such requirement cannot be stated at the present time.

Physical Properties

6. The fabricated product shall conform to the requirements prescribed in Table I.

Desaturated Fabric

7. The desaturated woven cotton fabric shall conform to the following requirements:

Average dry weight per square yard, min	3½ oz.
Ash (based on dry weight of fabric), max	2 per cent.
Composition of fabric	not less than 100 per cent[a] of cotton fibers
Thread count per inch:	
Warp	26 to 32
Filling	24 to 32

[a] This shall not exclude the presence of the customary sizing materials in amounts not exceeding 8 per cent by weight of the moisture-free cotton.

Packing

11. The rolls of treated cotton fabric shall be wound on mandrels or rigid hollow fiber cylinders not less than 2 in. in diameter or 2 in. square, extending not more than 4 in. beyond the ends of the rolls. They shall be securely tied or wrapped in a manner that will prevent unrolling in transit.

Sampling and Testing

12. The material shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the Tentative Methods

of Testing Felted and Woven Fabrics Saturated with Bituminous Substances for Use in Waterproofing and Roofing (A.S.T.M. Designation: D 146).[3]

Inspection

13. Inspection of material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

Basis of Rejection

14. Failure to conform to any one of the requirements prescribed in these specifications shall constitute grounds for rejection. In case of rejection, the seller shall have the right to reinspect the rejected shipment and resubmit the lot after removal of those packages not conforming to the specified requirements.

Standard Specifications for

WIDE SELVAGE ASPHALT ROOFING SURFACED WITH COARSE MINERAL GRANULES[1]

A.S.T.M. Designation: D 371 - 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 371; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover asphalt roofing in sheet form, either 36 or 32 in. in width, composed of asphalt-saturated roofing felt coated on approximately one half of the width of the weather side with asphalt, and surfaced on the coated portion with mineral granules. This roofing is used as a cap sheet in the construction of built-up roofs.

Manufacture

2. In the process of manufacture, a single thickness of dry roofing felt shall be impregnated with a hot asphaltic saturant, then coated on the weather side for approximately one half the width of the sheet with an asphaltic coating (compounded with a fine mineral filler substantially insoluble in water), and surfaced by embedding mineral granules in the hot asphaltic coating. The coated and surfaced portion shall be 17 in. in width on 36-in. roofing and 15 in. in width on 32-in. roofing.

Character of Felt

3. The felt shall be a roofing felt produced by "felting" vegetable or animal fibers or mixtures thereof. The surface of the felt shall be uniformly smooth. Upon splitting or tearing on the bias, the felt shall appear reasonably free from lumps of underbeaten stock and particles of foreign substances (that is, fragments of stone, metal, leather, rubber, etc.).

Character of Saturant and Coatings

4. The bitumen of the saturant and coatings shall be composed of asphaltic materials.

Character of Saturated Felt

5. The felt shall be thoroughly and uniformly saturated, and shall show no unsaturated spots at any point upon

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1933 to 1944, being revised in 1937, 1941, and 1944.

cutting 2-in. strips at random across the entire sheet and splitting them open for their full length.

Surface Finish

6. (*a*) The surface of the weather side shall be uniform in finish and texture. The mineral granules on the surfaced portion shall be uniformly distributed in a smooth layer and shall be firmly embedded in the asphalt coating.

(*b*) The line between the surfaced and unsurfaced portion shall be straight and shall run parallel longitudinally to the edge of the sheet. The surfaced portion shall be 17 ± ½ in. on 36-in. roofing and 15 ± ½ in. on 32-in. roofing.

(*c*) The reverse side of the sheet may or may not be coated. If coated, it may be surfaced with a small amount of mineral matter to prevent sticking in the roll.

Physical Properties

7. The fabricated product shall conform to the requirements prescribed in Table I.

Freedom from Defects

8. The finished material shall be free of visible external defects, such as holes, ragged or untrue edges, breaks, cracks, tears, protuberances, and indentations.

Pliability and Stickiness

9. The finished product shall not crack nor be so sticky as to cause tearing or material damage upon being unrolled at atmospheric temperatures above 50 F. (10 C.).

Packing

10. (*a*) Cap sheets shall be put up in rolls, containing sufficient material to cover not less than 50 sq. ft. No roll shall contain more than two pieces nor shall there be more than 3 per cent of rolls containing two pieces in any shipment. The rolls shall be tightly wound, and shall be securely wrapped in a substantial grade of paper completely

TABLE I.—PHYSICAL REQUIREMENTS FOR ASPHALT CAP SHEET.

Width	The roofing shall be put up in rolls and shall be either 36 or 32 in. in width, as may be specified, within a permissible variation of ±¼ in.			
Area	The average area of the rolls examined shall contain sufficient roofing to cover 50 sq. ft. of roof surface: for roofing 32 in. in width, 107.3 sq. ft. ± 5 per cent, and for roofing 36 in. in width, 106.8 sq. ft. ± 5 per cent.			
Pliability at 77 F. (25 C.)[a]	At least 8 strips out of 10 from the granule-surfaced portion shall not crack when bent 90 deg. at a uniform speed over a rounded corner of ¾-in. radius.			
Behavior on heating to 176 F. (80 C.) for 2 hr.[a]	Not more than 1.5 per cent volatile matter loss. The granular surfacing shall not slide more than ¼ in. when suspended vertically.			
	45-lb. Grade		55-lb. Grade	
	Max., lb.	Min., lb.	Max., lb.	Min., lb.
Weight per roll, net average	....	42	. . .	52
Weight of dry felt per 108 sq. ft.	....	7.1	. . .	10.8
Weight of saturant (soluble in CS_2) per 108 sq. ft.[b]	....	10.0	....	17.5
Weight of weather side mineral filled coating per 108 sq. ft.[a]	35.0	16.0	35.0	16.0
Weight of weather side mineral matter passing No. 6 (3360-micron) and retained on No. 100 (149-micron) sieve per 108 sq. ft.[a]	....	20.0	....	20.0
Percentage by weight of mineral matter passing No. 100 (149-micron) sieve on the basis of the sum of the bitumen in the coatings and the mineral matter passing No. 100 (149-micron) sieve	50.0 per cent	15.0 per cent	50.0 per cent	15.0 per cent
Weight of any 108 sq. ft. roll of roofing in shipment	....	40.0	....	50.0

[a] Granule-surfaced portion.

[b] The weight of saturant per 108 sq. ft. shall be not less than 1.4 times the weight of the dry felt on the 45-lb. grade and 1.6 times the weight of the dry felt on the 55-lb. grade.

encircling the roll and pasted at the overlap in such a manner as to prevent shifting from position.

(*b*) Special packing shall be as agreed upon by the purchaser and the seller.

Marking

11. Each roll shall be plainly marked with the manufacturer's name and brand.

Sampling and Testing

12. The material shall be sampled and the properties enumerated in these specifications shall be determined in accordance with the Tentative Methods of Testing Asphalt Roll Roofing, Cap Sheets, and Shingles (A.S.T.M. Designation: D 228) of the American Society of Testing Materials.[3]

Inspection

13. Inspection of material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

Basis of Rejection

14. Failure to conform to any one of the requirements prescribed in these specifications shall constitute grounds for rejection. In case of rejection, the seller shall have the right to reinspect the rejected shipment and resubmit the lot after removal of those packages not conforming to the specified requirements.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Standard Specifications for

ASPHALT SIDING SURFACED WITH COARSE MINERAL GRANULES[1]

A.S.T.M. Designation: D 699 – 44

ADOPTED, 1944.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 699; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. (*a*) These specifications cover asphalt siding in strip or individual form surfaced with colored mineral granules, composed of roofing felt saturated and coated on both sides with asphalt and surfaced on the weather side with granulated slate or equivalent mineral material (of solid or mixed colors as may be agreed upon by the purchaser and the seller), and on the reverse side with a surfacing material.

(*b*) Siding shingles supplied under these specifications are intended to be used with a "headlap" (Note) of not less than 1 in.

NOTE.—The headlap is the shortest vertical distance between the top of cutout or bottom edge of a course of siding and the most proximate underlying area of sidewall not covered by preceding courses of siding.

Manufacture

2. In the process of manufacture, a single thickness of dry roofing felt shall be impregnated with a hot asphaltic saturant, then coated on both sides with a hot asphaltic coating compounded with a fine mineral filler substantially insoluble in water, and finally surfaced on the weather side with mineral granules embedded in the hot asphaltic coating. The reverse side shall be covered with a suitable material to prevent sticking in the package.

Character of Felt

3. The surface of the felt shall be uniformly smooth. Upon splitting or tearing on the bias, the felt shall appear reasonably free from lumps of underbeaten stock and particles of foreign substances (that is, fragments of stone, metal, leather, rubber, etc.)

Character of Saturant and Coatings

4. The bitumen of the saturant and coatings shall be composed of asphaltic materials.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1942 to 1944, being revised in 1944.

Character of Saturated Felt

5. The felt shall be completely and uniformly saturated, and shall show no unsaturated spots at any point upon cutting 2-in. strips at random across the entire piece and splitting them open for their full length.

Surface Finish

6. (*a*) The surface of the weather side shall be uniform in finish and may be embossed to simulate a grained texture. The mineral granules shall cover the entire surface and shall be firmly embedded in the asphalt coating.

(*b*) The reverse side shall have a coating of asphalt and shall be surfaced with suitable material to prevent sticking.

Physical Properties

7. The fabricated product shall conform to the requirements prescribed in Table I.

Freedom from Defects

8. The finished material shall be free of visible external defects, such as holes, ragged or untrue edges, rents, cracks, indentations, and lumps of coating.

Stickiness

9. The siding shall not stick together in the packages so as to cause damage upon being unpacked at atmospheric temperatures above 50 F. (10 C.).

Packing

10. The siding shall be packed in cardboard cartons or between wood or cardboard ends and tied securely so as to make a substantial package weighing not more than 135 lb., gross.

Marking

11. Each package shall be plainly marked with the name and brand of the manufacturer, as well as the style, type, and color of the finished product. Direction sheets for application shall be included in at least every fifth package.

Sampling and Testing

12. The material shall be sampled and the properties enumerated in these specifications shall be determined in ac-

TABLE I.—PHYSICAL REQUIREMENTS OF ASPHALT SIDING.

Shape	The form and size of the shingles shall be as agreed upon between the purchaser and the seller.		
Area	Sufficient material per "square" shall be furnished to adequately waterproof 100 sq. ft. of sidewall area.		
Behavior on heating to 176 F. (80 C.) for 2 hr	Not more than 1.5 per cent volatile matter loss. The granular surfacing shall not slide more than 1/8 in. when suspended vertically.		
	Regular Weight, lb.		
	Max.	Min.	
Weight, net average per 100 sq. ft.[a]	...	75	
Weight of dry felt per 100 sq. ft.	...	10.0	
Weight of saturant per 100 sq. ft.[b]	...	17.5	
Weight of weatherside mineral filled coating per 100 sq. ft.	...	10	
Weight of mineral matter per 100 sq. ft. passing No. 6 (3360-micron) and retained on No. 100 (149-micron) sieve	...	18.5	
Percentage by weight of mineral matter passing No. 100 (149-micron) sieve on the basis of the sum of the bitumen in the coatings and the mineral matter passing No. 100 (149-micron) sieve	50	15	
Weight of siding per 100 sq. ft. (individual package)	...	72	

[a] Weight, net average per 100 sq. ft. $= \frac{\text{net wt. of packages inspected}}{\text{sq. ft. area per siding piece} \times \text{no. of pieces}} \times 100$.

[b] The weight of saturant per 100 sq. ft. shall be not less than 1.75 times the weight of the dry felt.

cordance with the Tentative Methods of Testing Asphalt Roll Roofing, Cap Sheets, and Shingles (A.S.T.M. Designation: D 228) of the American Society for Testing Materials.[3]

Inspection

13. Inspection of material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

Basis of Rejection

14. Failure to conform to any one of the requirements prescribed in these specifications shall constitute grounds for rejection. In case of rejection, the seller shall have the right to reinspect the rejected shipment and resubmit the lot after removal of those packages not conforming to the specified requirements.

Standard Methods of

TESTING BITUMINOUS MASTICS, GROUTS, AND LIKE MIXTURES[1]

A.S.T.M. Designation: D 147 – 41

ADOPTED, 1941.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 147; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These methods cover the procedures for testing bituminous mastics, grouts, and like mixtures, which may be classified and defined as follows:

Bituminous Grout.—A mixture of bituminous material as a binder and sandy mineral matter as an aggregate, which when heated to a suitable temperature becomes sufficiently fluid to flow into place without mechanical manipulation, and which on cooling congeals to a compact mass.

Asphalt Mastic.—A mixture containing (1) asphaltic material as a binder and graded mineral matter as an aggregate, or (2) pulverized native rock asphalt (to which asphaltic material may have been added); either of which when heated to a suitable temperature may be poured into place but which requires trowelling to form it into a compact mass.

Asphalt Mastic Cake.—A mixture containing asphaltic material as a binder and an aggregate consisting chiefly of calcareous or siliceous dust cast into the form of blocks or "cakes" and adapted for use in preparing asphalt mastic.

Preparation of Samples

2. (*a*) Bituminous grouts shall be heated in an oven or on a hot plate in a pan or other suitable container at the lowest possible temperature to prevent overheating and volatilization, and, when sufficiently fluid, shall be thoroughly stirred to insure a uniform sample, whereupon 10 to 30 g. shall be taken for analysis.

(*b*) Asphalt mastics or mastic cake shall be warmed on a hot plate or in a hot oven until soft enough to be broken up or stirred so that a representative sample for analysis may be taken. The amount taken for analysis will depend upon the amount of coarse gravel or stone in the mixture. The larger the

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to their present adoption as standard, these methods were published as tentative from 1922 to 1927, being revised in 1923, 1924, 1925, and 1927. They were adopted in 1927, published as standard from 1927 to 1939, but withdrawn, revised, and republished as tentative from 1939 to 1941.

Emergency Alternate Provisions EA – D 147 applying to this standard appear in the pink section of this book.

gravel or stone, the larger will be the sample required for accuracy. The size of samples to be taken shall be as follows: Where all particles pass a No. 10 (2000-micron) sieve, 10 to 30 g.; where 25 per cent of the aggregate is retained on a No. 10 sieve, 50 g.; where 50 per cent of the aggregate is retained on a No. 10 sieve, 100 g.; and where 75 per cent of the aggregate is retained on a No. 10 sieve, 200 g.

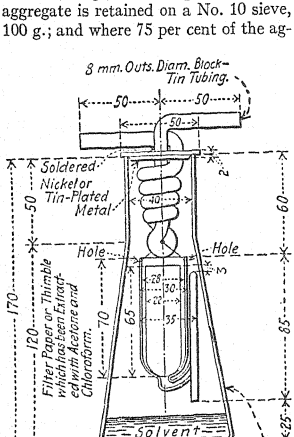

FIG. 1.—Extraction Apparatus for Analysis of 10 to 30-g. Samples.

NOTE.—Where the properties of the extracted bituminous matter are to be determined, 500 g. shall be taken and extracted with pure benzol as described in Sections 3 (*b*) and 5 and examined as specified in Section 6.

Apparatus

3. (*a*) *For Analysis of 10 to 30-g. Samples.*—In cases where a 10 to 30-g. sample is sufficient, the analysis shall be carried out by means of the glass extractor, shown in Fig. 1.

(*b*) *For Analysis of 50 to 500-g. Samples.*—The apparatus for analysis of samples containing coarser aggregate shall be the large extractor, shown in Fig. 2, consisting of a large brass cylinder, through the bottom of which projects a 16-candlepower, incandescent carbon filament bulb or other type of electric heater of correct capacity to supply heat to the extraction apparatus proper, held in the upper portion of the cylinder. This apparatus shall consist of a cylindrical brass vessel for holding the solvent, a cylindrical wire basket made of 80-mesh wire cloth suspended in the cylinder, and an inverted conical condenser which serves as a top.

Procedure for Analysis of 10 to 30-g. Samples[3]

4. (*a*) An ordinary Whatman or S. and S. filter thimble shall be dried and weighed. The weighed sample shall be placed in the thimble and 40 to 50 ml. of CS_2[4] poured over the sample. The thimble containing the sample shall be suspended under the condenser by a fine wire bail as shown in Fig. 1. The flask shall be cautiously heated by a steam-bath or electric heater just enough to vaporize the solvent. Cold water shall be circulated through the condenser. The heat evaporates the carbon disulfide in the flask. This condenses upon the condenser and drops back upon the sample through which it filters, thus dissolving out the bitumen which collects in the bottom of the flask. The extraction should be discontinued when the

[3] This method for analysis of larger samples is especially adapted for asphalt mastics, grouts, and mastic cake. If the binder is coal-tar pitch, the "free carbon" constituent of the binder will remain with the mineral aggregate. The committee has under consideration a possible separate method for analysis of coal-tar mastics.

[4] Carbon tetrachloride, benzol, or chloroform may be used instead of carbon disulfide, with the only difference that in the case of noninflammable solvents, the solvent will have to be evaporated from the solution of bitumen to determine the ash for correction instead of burning off directly. When the solvent is expelled, the bitumen can be ignited for ash.

CS_2 drops colorless from the filter. The time of extraction will depend upon the nature of the bitumen and mineral aggregate in the sample and upon the degree of heat applied, the coldness of the water in the condenser, and other factors. In some cases extraction may be complete in 1 hr., in others 4 or 5 hr. may be necessary. When the solvent comes through clear, the filter shall be removed and washed with a fine jet of CS_2 from a washing bottle to wash out any bitumen that may be retained at the top of the paper and to break up any channels that may have been formed by the CS_2 passing through. If the washings show any color, the thimble shall be put back and extraction continued until the solvent again becomes colorless. It shall then be removed, dried carefully, at a low temperature at first to prevent ignition of the absorbed CS_2, and finally to constant weight at 100 C. (212 F.), cooled, and weighed. The solution in the flask shall be rinsed into a weighed porcelain or silica evaporating dish or crucible and the solvent burned off under a hood. The residue shall be ignited over a flame or in a muffle and the ash weighed and the weight added to that of the mineral matter in the filter paper. This is to correct for the fine mineral matter which will be carried through the paper by the solvent. Should there be a considerable amount of ash recovered in this way, and if it is found that the mineral matter is calcium or other carbonate, it shall be recarbonated by repeated treatment with ammonium carbonate solution and finally ignited at a dull red heat. Ordinarily, however, the mineral matter going through the paper will be so small in amount that the difference caused by ignition may be neglected. The corrected loss in weight on the original sample represents the percentage of bitumen.

(*b*) The sieve analysis of the mineral aggregate shall be made in accordance with the Standard Method of Test for Sieve Analysis of Fine and Coarse Aggregates (A.S.T.M. Designation: C 136) of the American Society for Testing Materials.[5] The extracted residue shall be transferred from the thimble to the No. 200 (74-micron) sieve, the paper being gently rubbed to free adhering particles. The aggregate on the sieve shall be gently rubbed with the fingers to break up lumps and to free any particles of fine dust that might adhere to larger sand particles. The sieve shall be shaken over a piece of paper from side to side with the right hand, striking it sharply against the palm of the left hand until no appreciable amount of dust comes through the sieve on to the paper. The paper shall be cleared from time to time by raising one side with the left hand and rolling off the siftings, so that it can be seen when the sifting is complete. The material remaining on the No. 200 sieve shall be weighed and the amount of material which has passed through the No. 200 sieve shall be determined by difference. This operation shall be repeated upon the coarser sieves in order and the amount passing each sieve and retained on the next finer recorded as percentage of the original sample.

Procedure for Analysis of 50 to 500-g. Samples

5. (*a*) A large filter paper, 12 or 13 in. in diameter, shall be fitted inside the wire basket of the extractor, shown in Fig. 2, by folding once more than in ordinary filtering, or by wrapping it over a form which fits inside the basket (a cylindrical bottle of proper size makes a good form) and placing it inside the basket. The basket with contained filter paper shall be dried and weighed.

[5] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

The sample shall be weighed and packed in the filter paper in the basket. Care should be taken not to pack all coarse particles in one place and the fine particles in another but to have them mixed together in uniform proportions. The sample shall be covered with a disk of felt or wad of absorbent cotton to insure even distribution of the dropping solvent, thus preventing it from forming a channel through the sample. The basket shall be suspended in the extractor and 150 to 200 ml. of CS_2[4] poured over the felt or cotton. The condenser shall be placed over the top and water circulated through it. Current shall be started through the electric lamp underneath the extractor and the extraction carried on exactly as in the smaller glass extractor, but on a larger scale. The time for extraction will vary from 3 to 12 hr. or more, depending upon the nature of the sample. To determine when extraction is complete, the condenser shall be raised and the basket lifted out to observe if drippings are clear. One or two drops caught upon white filter paper should leave but a light stain.

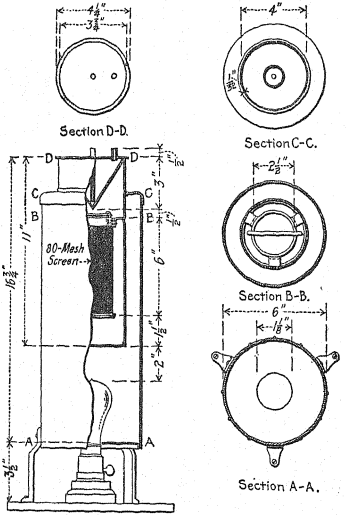

FIG. 2.—Extraction Apparatus for Analysis of 50 to 500-g. Samples.

(*b*) The drying and weighing of the basket, burning off of the solution for correction, and the sifting of the mineral aggregate shall be carried on exactly as in the case of the smaller sample as described in Section 4, except that in sifting mineral aggregates containing coarse stone, it is well to remove the stone by putting the mineral aggregate first through a No. 10 (2000-micron) sieve, as

the large stone would injure the No. 200 (74-micron) sieve.

(*c*) The stone removed by the No. 10 sieve may be sieved through ¼-in., ½-in., and coarser sieves in order, as described in the Standard Method C 136,[5] and the fine material passing the No. 10 sieve through No. 200 and coarser sieves in order, all amounts passing any one sieve and retained on the next finer one being reported as percentage of the original sample. Thus the ingredients of the mixture may be roughly separated by the use of the proper size sieves, and examined for physical and chemical characteristics.

NOTE.—The siftings passing the No. 200 (74-micron) sieve will consist largely of the dust or pulverized rock used in the mixture. The material between the No. 100 (149-micron) and the No. 10 (2000-micron) will consist largely of the sand used in the mixture, with any particles of fine crushed stone within these limits that existed in the original materials. Gravel or broken stone as a rule will be larger than No. 10 or No. 8 (2380-micron).

Recovery and Examination of Extracted Bitumen

6. Until standard methods are available, recovery and preparation for test of the bituminous matter soluble in pure benzol extracted from asphalt mastics and grouts shall be made according to the procedure described in the paper "Method and Apparatus for the Recovery of Asphalt."[6]

[6] Gene Abson, "Method and Apparatus for the Recovery of Asphalt," *Proceedings*, Am. Soc. Testing Mats. Vol. 33, Part II, p. 704 (1933).

Solubility of Aggregate in Hydrochloric Acid

7. When the mastic is to be used for acid-proof floors, tank linings, etc., pulverized silica and other materials insoluble in acid are used in preparing the mixture. The most important chemical property, therefore, is solubility or insolubility in mineral acids. This determination may be carried out in the following manner:

Dry to constant weight at 325 F. about 2.5 g. of the dust, or of the coarser material, or stone which has been previously pulverized in a mortar. The loss will represent any moisture that may have been retained in the material as well as any absorbed solvent that may not have been expelled while drying the sample after extraction. Place 1 g. of the dried sample in a 250-ml. beaker, cover with a watch glass and add 10 ml. of c. p. HCl (sp. gr. 1.19), dilute with 50 ml. of distilled water. Break up any lumps by means of a glass stirring rod. Note any effervescence which may occur. If considerable effervescing takes place, the sample may be said to be carbonate. If all the sample, or practically all, dissolves, the determination need not be carried further. If apparently insoluble, heat it carefully and boil for 15 min., and filter through a tared Gooch filter, and wash the insoluble residue with hot water. Ignite and weigh and report the loss as the percentage soluble in hydrochloric acid.

Standard Method of Test for

COARSE PARTICLES IN MIXTURES OF ASPHALT AND MINERAL MATTER[1]

A.S.T.M. Designation: D 313 – 41

ADOPTED, 1941.[2]

Reapproved in 1944 Without Change.

This Standard of the American Society for Testing Materials is issued under the fixed designation D 313; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method of test covers the procedure for determining the amount of particles of mineral or other insoluble matter in asphaltic mixtures that are retained upon a No. 200 (74-micron) sieve.

Sampling

2. The material shall be sampled in accordance with the Tentative Methods of Sampling Bituminous Materials (A.S.T.M. Designation: D 140) of the American Society for Testing Materials.[3]

Preparation of Sample

3. The sample as received shall be completely melted in an oven at the lowest possible temperature, stirred well to insure homogeneity, and samples for test taken immediately.

Apparatus

4. (*a*) The apparatus shall consist either of a 3-in. No. 200 (74-micron) sieve or, a crucible sieve, $1\frac{3}{4}$ in. in diameter at the top and $1\frac{1}{4}$ in. in diameter at the bottom containing a No. 200 (74-micron) sieve. The sieve shall conform to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials.[3]

(*b*) A 3-in. No. 200 (74-micron) sieve for comparison purposes shall be retained in the laboratory as a standard. Whenever a new sieve is secured, a practical test of its accuracy should be made by running on it, and on the standard sieve, a comparison test, using powdered mineral matter that has a considerable percentage of coarse particles. A reserve stock of such powdered mineral filler should be kept for this purpose.

Procedure

5. (*a*) The sieve shall be dried in an oven at 105 to 110 C., cooled, and then weighed on an analytical balance, the weight being recorded to the nearest 1 mg.

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, these specifications were published as tentative from 1929 to 1941, being revised in 1935 and 1937.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

(*b*) A sample of the asphalt sufficient to yield about 1 g. of mineral matter shall be weighed into a 400-ml. beaker. Then carbon disulfide, carbon tetrachloride, or benzol shall be added and the mixture warmed until the asphalt is entirely dissolved. The solution obtained shall be poured through the weighed sieve, and the residue in the beaker shall be washed onto the sieve, using the solvent employed.

(*c*) The sieve containing the residue shall be washed with a fine jet of the solvent from a wash bottle until free from asphalt and fine mineral matter, then dried, tapped lightly to remove any fine mineral matter held on the wires, and weighed. During the washing, the sieve shall be held so that the liquid will drain through readily.

Calculation

6. The percentage of coarse particles in the mineral matter shall be calculated from the weight of the sample taken, the percentage of matter insoluble in carbon disulfide, and the weight of the residue retained on the sieve.

Standard Method of Test for

SIEVE ANALYSIS OF GRANULAR MINERAL SURFACING FOR ASPHALT ROOFING AND SHINGLES[1]

A.S.T.M. Designation: D 451 - 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 451; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method is intended for the sieve analysis of granular mineral surfacing material, such as crushed slate, stone, etc., used on the weather surface of prepared asphalt roofing and shingles.

Apparatus

2. (*a*) *Sieves.*—A set of consecutive sieves of the series listed in Table I, conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[3] shall be used. The group of sieves selected shall include those appropriate to the grading of the granular mineral to be subjected to sieve analysis. Sieves of either the coarser or finer openings, on which less than 0.05 per cent of the weight of the sample of the particular material would be found after sieving, need not be included in the set. The wire cloth for these sieves shall be woven (not twilled) from brass, bronze, or other suitable wire, and shall be mounted without distortion in circular frames, 8 in. (20.32 cm.) in diameter and about 2 in. (5 cm.) between the top of the frame and the cloth.

(*b*) *Sieve Shaker.*—A mechanically operated sieve shaker, which imparts to the set of sieves a rotary motion and tapping action of uniform speed, shall be used. The number of taps per minute shall be between 140 and 160. The sieve shaker shall be fitted with a hard maple plug to receive the impact of the tapping device. The entire apparatus shall be rigidly mounted by bolting to a solid foundation, preferably of concrete.

(*c*) *Sample Splitter.*—A riffle sampler with $\frac{3}{8}$ or $\frac{1}{2}$-in. divisions, for reducing the gross sample to the quantity required for the sieve analysis, shall be used.

Unit for Sampling

3. Each carload of mineral granules shall be considered the unit for sampling,

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1937 to 1940.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

except that where a carload includes more than one kind of granular surfacing, the entire quantity of each kind in the car shall be considered the unit for each kind, respectively.

Collection of Gross Sample

4. (*a*) In collecting the gross sample from a carload of mineral granules shipped in bulk, eight equal increments of not less than 2 lb. each shall be taken from the material at the exposed surface of the car. A conical excavation about 1 ft. in depth shall be made at each sampling point and the sample taken from the bottom of the excavation. The eight sampling points shall be located as shown in Fig. 1.

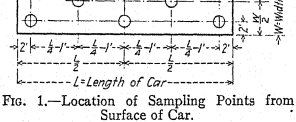

FIG. 1.—Location of Sampling Points from Surface of Car.

(*b*) In collecting the gross sample from a carload of mineral granules shipped in bags, a number of bags shall be selected at random, equivalent to the cube root of the total number of bags in the car. The gross sample shall consist of equal increments of not less than 2 lb. from each of the bags taken for sampling.

(*c*) Where the mineral granules are being loaded or unloaded by conveyor or chute the gross sample shall preferably be collected by taking equal increments from the stream at regular time intervals, with such frequency that the total weight of the gross sample will be not less than 16 lb. Increments shall be taken from the full width and thickness of the stream, preferably, if practicable, by inserting a suitable container into the stream.

TABLE I.—NOMINAL DIMENSIONS, PERMISSIBLE VARIATIONS, AND LIMITS FOR WOVEN WIRE CLOTH OF STANDARD SIEVES.

Size or Sieve Designation	Sieve Opening		Permissible Variation in Average Opening, per cent	Permissible Variation in Maximum Opening, per cent	Wire Diameter	
	mm.	in. (approx. equivalents)			mm.	in. (approx. equivalents)
3360 micron (No. 6).....	3.36	0.132	±3	+10	0.87 to 1.32	0.034 to 0.052
2380 micron (No. 8).....	2.38	0.0937	±3	+10	0.74 to 1.10	0.0291 to 0.0433
1680 micron (No. 12).....	1.68	0.0661	±3	+10	0.62 to 0.90	0.0244 to 0.0354
1190 micron (No. 16).....	1.19	0.0469	±3	+10	0.50 to 0.70	0.0197 to 0.0276
840 micron (No. 20).....	0.84	0.0331	±5	+15[a]	0.38 to 0.55	0.0150 to 0.0217
590 micron (No. 30).....	0.59	0.0232	±5	+15[a]	0.29 to 0.42	0.0114 to 0.0165
420 micron (No. 40).....	0.42	0.0165	±5	+25[a]	0.23 to 0.33	0.0091 to 0.0130
297 micron (No. 50).....	0.297	0.0117	±5	+25[a]	0.170 to 0.253	0.0067 to 0.0100
210 micron (No. 70).....	0.210	0.0083	±5	+25[a]	0.130 to 0.187	0.0051 to 0.0074
149 micron (No. 100).....	0.149	0.0059	±6	+40[a]	0.096 to 0.125	0.0038 to 0.0049

[a] Not more than 5 per cent of the openings shall exceed the nominal opening by more than one half of the permissible variation in maximum opening.

Reduction of Gross Sample

5. The gross sample shall be reduced by riffling or hand-quartering to not less than 500 g. (1.1 lb.).

Size of Test Sample

6. The entire sample obtained from reduction of the gross sample, shall be weighed with an accuracy of not less than 0.1 g., and taken for the sieve analysis.

Sieve Analysis

7. (*a*) The group of sieves selected from the series listed in Table I shall be assembled in consecutive order as to size of openings, with the sieve having the largest openings at the top and the

one with the smallest openings at the bottom, the assembly being completed by a solid collecting pan below the bottom sieve. The test sample, previously weighed (Section 6), shall be placed on the top sieve and this sieve closed with a solid cover. The sieve assembly shall then be securely fastened in a suitable mechanical sieve shaking device (Section 2 (*b*)).

(*b*) The sample shall be passed through the sieves of the series selected, by subjecting it to the action of the sieve shaker for a period of 15 min. Since granular mineral surfacing materials usually have been subjected to grading by screens in the process of manufacture and hence separate rapidly into their sieve fractions, an end point determination is not considered necessary.

(*c*) The portion of the sample retained on each of the sieves and on the pan shall be carefully removed and weighed with an accuracy of not less than 0.1 g.

Report

8. The results of the sieve analysis shall be reported to the nearest 0.1 per cent (omitting the results on those sieves on which less than 0.05 per cent of the total weight of the test sample was collected), as follows:

Retained on Sieve	Passing Sieve	Per Cent
3360-micron (No. 6)		.....
2380-micron (No. 8)	3360-micron (No. 6)	.....
1680-micron (No. 12)	2380-micron (No. 8)	.....
1190-micron (No. 16)	1680-micron (No. 12)	.....
840-micron (No. 20)	1190-micron (No. 16)	.....
590-micron (No. 30)	840-micron (No. 20)	.....
420-micron (No. 40)	590-micron (No. 30)	.....
297-micron (No. 50)	420-micron (No. 40)	.....
210-micron (No. 70)	297-micron (No. 50)	.....
149-micron (No. 100)	210-micron (No. 70)	.....
	149-micron (No. 100)	.....
Total		.....

The sum of the sieve weight percentage fractions, reported as above tabulated, shall be not less than 99.5 per cent, that is, the total loss and error in the sieve analysis shall not exceed 0.5 per cent.

Reproducibility of Results

9. Duplicate determinations by the same operator, using the same sieves, shall check within 1 per cent of the total weight of the sample, for the portion of the sample retained on each sieve and on the pan.

Standard Method of Test for

SIEVE ANALYSIS OF NONGRANULAR MINERAL SURFACING FOR ASPHALT ROOFING AND SHINGLES[1]

A.S.T.M. Designation: D 452 – 40

ADOPTED, 1940.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 452; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. This method is intended for the sieve analysis of nongranular mineral surfacing material, such as mica, talc and other powdered or flaky mineral particles, used on the weather surfaces of prepared asphalt roofing and on the non-weather-exposed surface of asphalt shingles.

Apparatus

2. (*a*) *Sieves.*—A set of consecutive sieves of the series listed in Table I, conforming to the Standard Specifications for Sieves for Testing Purposes (A.S.T.M. Designation: E 11) of the American Society for Testing Materials,[3] shall be used. The group of sieves selected shall include those appropriate to the grading of the nongranular mineral to be subjected to sieve analysis. Sieves of either the coarser or finer openings, on which less than 0.05 per cent of the weight of the sample of the particular material would be found after sieving, need not be included in the set (Note). The wire cloth for these sieves shall be woven (not twilled) from brass, bronze, or other suitable wire, and shall be mounted without distortion in circular frames, 8 in. (20.32 cm.) in diameter and about 2 in. (5 cm.) between the top of the frame and the cloth.

NOTE.—For relatively coarse or flaky materials, such as coarse mica, sieves from 1190 to 210-micron (Nos. 16 to 70) inclusive, will usually be found suitable; for finer surfacing materials, such as fine mica or talc flour, sieves from 590 to 74-micron (Nos. 30 to 200) inclusive, will usually give a satisfactory sieve analysis.

(*b*) *Sieve Shaker.*—A mechanically operated sieve shaker, which imparts to the set of sieves a rotary motion and tapping action of uniform speed, shall be used. The number of taps per minute shall be between 140 and 160. The sieve shaker shall be fitted with a hard maple plug to receive the impact of the tapping device. The entire apparatus shall be rigidly mounted by bolting to

[1] Under the standardization procedure of the Society, this method is under the jurisdiction of the A.S.T.M. Committee D-8 on Bituminous Waterproofing and Roofing Materials.

[2] Prior to adoption as standard, this method was published as tentative from 1937 to 1940.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

a solid foundation, preferably of concrete.

(*c*) *Sample Splitter.*—A riffle sampler with $\frac{3}{8}$ or $\frac{1}{2}$-in. divisions, for reducing the gross sample to the quantity required for the sieve analysis, shall be used.

Unit for Sampling

3. Each carload of nongranular mineral surfacing shall be considered the unit for sampling.

Collection of Gross Sample

4. (*a*) In collecting the gross sample from a carload of nongranular mineral surfacing shipped in bags, a number of bags shall be selected at random equivalent to the cube root of the total number of bags in the car. The gross sample shall consist of equal increments of not less than 0.5 lb. from each of the bags taken for sampling.

(*b*) In collecting the gross sample from a carload of nongranular mineral surfacing material shipped in bulk, at least eight equal increments of not less than 0.5 lb. each shall be taken from well distributed points in the mass, using a sampling tube not less than 1 in. in diameter. A conical excavation about 1 ft. in depth shall be made at each sampling point and the sampling tube inserted into the mass at the bottom of the excavation.

Reduction of Gross Sample

5. The gross sample shall be reduced by riffling or hand-quartering to not less than 100 g. (0.22 lb.).

Size of Test Sample

6. The entire sample obtained from reduction of the gross sample, shall be dried at least 2 hr. in an oven at 220 F., weighed with an accuracy of not less than 0.1 g., and taken for the sieve analysis.

TABLE I.—NOMINAL DIMENSIONS, PERMISSIBLE VARIATIONS, AND LIMITS FOR WOVEN WIRE CLOTH OF STANDARD SIEVES.

Size or Sieve Designation	Sieve Opening		Permissible Variation in Average Opening, per cent	Permissible Variation in Maximum Opening, per cent	Wire Diameter	
	mm.	in. (approx. equivalents)			mm.	in. (approx equivalents)
1680 micron (No. 12).....	1.68	0.0661	±3	+10	0.62 to 0.90	0.0244 to 0.0354
1190 micron (No. 16).....	1.19	0.0469	±3	+10	0.50 to 0.70	0.0197 to 0.0276
840 micron (No. 20).....	0.84	0.0331	±5	+15[a]	0.38 to 0.55	0.0150 to 0.0217
590 micron (No. 30).....	0.59	0.0232	±5	+15[a]	0.29 to 0.42	0.0114 to 0.0165
420 micron (No. 40).....	0 42	0.0165	±5	+25[a]	0.23 to 0.33	0.0091 to 0.0130
297 micron (No. 50).....	0.297	0.0117	±5	+25[a]	0.170 to 0.253	0.0067 to 0.0100
210 micron (No. 70).....	0.210	0.0083	±5	+25[a]	0.130 to 0.187	0.0051 to 0.0074
149 micron (No. 100).....	0.149	0.0059	±6	+40[a]	0.096 to 0.125	0.0038 to 0.0049
74 micron (No. 200).....	0.074	0.0029	±7	+60[a]	0.045 to 0.061	0.0018 to 0.0024

[a] Not more than 5 per cent of the openings shall exceed the nominal opening by more than one half of the permissible variation in maximum opening.

Sieve Analysis

7. (*a*) The group of sieves selected from the series listed in Table I shall be assembled in consecutive order as to size of openings, with the sieve having the largest openings at the top and the one with the smallest openings at the bottom, the assembly being completed by a solid collecting pan below the bottom sieve. The test sample, previously weighed (Section 6), shall be placed on the top sieve and this sieve closed with a solid cover. The sieve assembly shall then be securely fastened in a suitable mechanical sieve shaking device (Section 2 (*b*)).

(*b*) The sample shall be passed through the sieves of the series selected, by subjecting it to the action of the sieve shaker for a period of 20 min. At the end of this period the collecting pan, containing the portion of the material passing the finest sieve of the group selected, shall be removed from the sieve assembly and the contents weighed with an accuracy of not less than 0.1 g. The collecting pan shall then be re-assembled with the sieves, as before, and the shaking continued for an additional 10 min. At the end of this additional shaking period the collecting pan shall be removed and the contents weighed. If the additional material passing the finest sieve during this second shaking period does not exceed 0.5 per cent of the total weight of the sample, the sieve analysis shall be considered complete. If it does exceed 0.5 per cent, the collecting pan and sieves shall be re-assembled and shaken for successive additional 10-min. periods, weighing the material collected in the pan after each period of shaking, until the amount passing the finest sieve in a 10-min. shaking period is less than 0.5 per cent of the weight of the sample.

(*c*) The portion of the sample retained on each of the sieves and on the pan shall be carefully removed and weighed with an accuracy of not less than 0.1 g.

Report

8. The results of the sieve analysis shall be reported to the nearest 0.1 per cent (omitting the results on those sieves on which less than 0.05 per cent of the total weight of the test sample was collected), as follows:

Retained on Sieve	Passing Sieve	Per Cent
1680-micron (No. 12)	.....	.....
1190-micron (No. 16)	1680-micron (No. 12)	.....
840-micron (No. 20)	1190-micron (No. 16)	.....
590-micron (No. 30)	840-micron (No. 20)	.....
420-micron (No. 40)	590-micron (No. 30)	.....
297-micron (No. 50)	420-micron (No. 40)	.....
210-micron (No. 70)	297-micron (No. 50)	.....
149-micron (No. 100)	210-micron (No. 70)	.....
74-micron (No. 200)	149-micron (No. 100)	.....
	74-micron (No. 200)	.....
Total	.....	.....

The sum of the sieve weight percentage fractions, reported as above tabulated, shall be not less than 98.5 per cent, that is, the total loss and error in the sieve analysis shall not exceed 1.5 per cent.

Reproducibility of Results

9. Duplicate determinations by the same operator, using the same sieves, shall check within 1 per cent of the total weight of the sample, for the portion of the sample retained on each sieve and on the pan.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: 06-1939

Standard Specifications for
ROUND TIMBER PILES[1]

A.S.T.M. Designation: D 25 - 37

ADOPTED, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 25; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover round timber piles to be used untreated, or treated by standard preservatives.

NOTE.—Where sawed timber is used as piling, such as heavy sheet piles, appropriate specifications should be selected from the Standard Specifications for Structural Wood Joist and Plank, Beams and Stringers, and Posts and Timbers (A.S.T.M. Designation: D 245) of the American Society for Testing Materials.[3]

Kinds of Wood

2. (*a*) The purchaser shall specify the kind or kinds of wood he desires, and shall designate the kinds he desires for preservative treatment.

NOTE.—Commonly used species are cedars, chestnut, cypress, Douglas fir, larch, oaks, pines, spruces, and tamarack.

(*b*) Piles of different kinds of wood shall be delivered in separate lots.

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-7 on Timber.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1915 to 1920. They were adopted in 1920, published as standard from 1920 to 1930, but withdrawn and republished as tentative from 1930 to 1937, being revised in 1934 and 1935.

[3] Appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

Use Classification

3. Timber piles are classified in these specifications under three general divisions according to the use intended, as follows:

(*a*) *Class A.*—Piles suitable for use in heavy railway bridges and trestles. The minimum diameter of butt assumes the use of load-bearing timber caps 14 in. in width.

(*b*) *Class B.*—Piles suitable for use in docks, wharves, highway work, and general construction. The minimum diameter of butt assumes the use of load-bearing timber caps 12 in. in width. When timber caps are not used, as in the case of piles under masonry foundations, the sizes given for Class C piles are recommended.

(*c*) *Class C.*—Piles suitable for use in foundations which will always be completely submerged, for coffer-dams, falsework, and sundry temporary work.

Class A and Class B Piles

General Quality

4. Except as hereinafter provided, Class A and Class B piles shall be free

from any defects which may impair their strength or durability as piling, such as decay, red heart, splits in piles to be treated, or splits longer than the measured butt diameter of piles not to be treated, twist of grain exceeding one-half of the circumference in any 20 ft. of length, unsound knots, numerous knots or holes, or shake more than one-third of the diameter of the pile. Piles which have been scored for turpentine shall be accepted, provided such scar does not exceed 36 in., and provided the scoring is of recent date showing the scar to be entirely sound and free from insect damage.

Knots

5. Sound knots will be permitted in Class A and Class B piles, provided they are not in clusters. The diameter of a sound knot shall not be greater than one-third of the minimum diameter of the pile at the section where it occurs, and shall not exceed 4 in. for piles 50 ft. and under in length. For piles over 50 ft. in length, knots between the section at mid-length and the butt shall conform to the limitation prescribed for piling under 50 ft. Between mid-length and the tip, single knots up to 5 in. in diameter will be permitted, provided they do not exceed one-half the minimum diameter of the pile at the section where they occur. The diameter of a knot shall be measured at right angles to the length of the pile.

General Requirements

6. (*a*) *Sound Timber.*—Class A and Class B piles shall be cut from sound, live trees, except that fire-killed, blight-killed, or wind-felled timber may be used if not attacked by decay or insects. Piles shall be cut above the ground swell.

(*b*) *Tip.*—The tip shall be sound.

(*c*) *Butt End.*—The butt end shall be sound except in cedar piles, which may have a pipe or stump rot hole not more than 1½ in. in diameter.

(*d*) *Taper.*—Piles shall have a gradual taper from the point of butt measurement to the tip.

(*e*) *Surface Finish.*—All knots and limbs shall be trimmed or smoothly cut flush with the surface of the pile. The butt and tip shall be sawed square with the axis of the pile, or the tip may be tapered to a point not less than 4 in. in diameter if directed by the engineer in charge.

Sapwood

7. (*a*) *Piles for Use Untreated.*—Piles for use without preservative treatment shall have as little sapwood as possible, and when used in exposed work, the diameter of the heartwood shall not be less than eight-tenths of the actual diameter of the pile at the butt.

(*b*) *Piles for Treatment.*—Piles for use with preservative treatment shall have no sapwood restrictions, but preferably shall contain as much sapwood as possible. In southern pine the sapwood thickness shall not be less than 1½ in. and in Douglas fir and larch not less than 1 in. on the butt end.

Peeled Piles

8. (*a*) Piles shall be peeled of bark, including the inner skin, soon after cutting so that the piles are smooth and clean. Care shall be taken to remove as little sapwood as possible while peeling the bark. The sapwood shall not be injured by unnecessary axe cuts. These piles shall be designated as piles for treatment.

(*b*) No pile shall be considered as thoroughly peeled unless all of the rough bark and at least 80 per cent of the inner bark which remains on the pile shall have been removed. In no case shall any piece of inner bark be over ¾ in. in width or over 8 in. in length, and

there shall be 1 in. of clean wood surface between any two strips of inner bark.

Diameter

9. (*a*) It is recommended that the diameters of piles measured under the bark shall conform to the requirements shown in Table I, subject to a permissible

TABLE I.—DIAMETERS OF THREE CLASSES OF PILES.

Length, ft.	Class A and Class B Piles (These differ in size only.)						Class C Piles[a] (These differ from Classes A and B in size and quality.)		
	Class A			Class B					
	Diameter 3 ft. from Butt, in.		Diameter of Tip, in.	Diameter 3 ft. from Butt, in.		Diameter of Tip, in.	Diameter 3 ft. from Butt, in.		Diameter of Tip, in.
	Minimum	Maximum	Minimum	Minimum	Maximum	Minimum	Minimum	Maximum	Minimum
DOUGLAS FIR AND SOUTHERN PINE PILES[b]									
Under 40.....	14	18	10	12	20	8	12	20	8
40 to 50, incl..	14	18	9	12	20	7	12	20	6
51 to 70, incl..	14	18	8	13	20	7	12	20	6
71 to 90, incl..	14	20	7	13	20	6	12	20	6
Over 90.....	14	20	6	13	20	5	12	20	5
BLACK OAK, CHESTNUT, CYPRESS, PIN OAK, POST OR BURR OAK, RED OAK, WHITE OAK, OR WILLOW OAK PILES									
Under 30.....	14	18	10	12	18	8	12	20	8
30 to 40, incl..	14	18	9	13	20	8	12	20	8
Over 40.....	14	18	8	13	20	7	12	20	6
CEDAR PILES									
Under 30.....	14	22	10	12	22	8	12	22	8
30 to 40, incl..	14	22	9	13	22	8	12	22	8
Over 40.....	14	22	8	13	22	7	12	22	7

[a] In Class C piles, a minimum diameter (at cut-off) of 10 in. may be specified for lengths of 30 ft. and under.
[b] Where larch, lodgepole or Norway pine, spruce, or tamarack piles are specified, their dimensions shall correspond to the requirements shown for Douglas fir and southern pine.

variation of minus $\frac{1}{2}$ in. in any diameter in not more than 25 per cent of the piles of that diameter.

(*b*) The diameter of a pile in cases where the tree is not exactly round shall be determined either by measuring the circumference and dividing the number of inches by 3.14, or by taking the average of the maximum and minimum diameters at the location specified.

Length

10. All piles shall be furnished cut to any of the following lengths, as specified: 16 to 40 ft. in multiples of 2 ft., and over 40 ft. in multiples of 5 ft. A variation of 6 in. in length shall be allowable, but the average length in any shipment shall be equal to, or greater than, the specified lengths. The length of each pile shall be legibly marked on the butt end with white or black paint.

Straightness

11. Piles shall be free from short or reversed bends, and free from crooks greater than one-half of the diameter of the pile at the middle of the bend. In short bends, the distance from the center of the pile to a line stretched from the center of the pile above the bend to the center of the pile below the bend shall not exceed 4 per cent of the length of the bend, or $2\frac{1}{2}$ in. A line drawn from the center of the butt end to the center of the tip shall lie within the body of the pile.

Class C Piles

General Quality

12. Class C piles shall be of sound, live timber that will stand driving, and need not be peeled if they are to be used without preservative treatment. They shall be free from decay and other imperfections such as bad knots and shakes which will materially affect their strength. Piles which have been scored for turpentine shall be accepted, provided such scar does not exceed 36 in., and provided the scoring is of recent date showing the scar to be entirely sound and free from insect damage.

General Requirements

13. (*a*) *Tip.*—The tip shall be sound.

(*b*) *Taper.*—Piles shall have a gradual taper from the point of butt measurement to the tip.

(*c*) *Surface Finish.*—All knots and limbs shall be trimmed or smoothly cut flush with the surface of the pile. The butt and tip shall be sawed square with the axis of the pile, or the tip may be tapered to a point not less than 4 in. in diameter if directed by the engineer in charge.

Sapwood

14. Sapwood requirements shall be identical with those for Class A and Class B piles as specified in Section 7.

Peeled Piles

15. The requirements for peeled piles shall be identical with those for Class A and Class B piles as specified in Section 8.

Diameter

16. The methods of measurement of diameter and the permissible variations in diameter shall be identical with those for Class A and Class B piles as specified in Section 9. The recommended sizes are given in Table I.

Length

17. The requirements for length shall be identical with those for Class A and Class B piles as specified in Section 10.

Straightness

18. The requirements relating to straightness shall be identical with those for Class A and Class B piles as specified in Section 11.

Standard Specifications for

WOODEN PAVING BLOCKS FOR EXPOSED PAVEMENTS[1]

A.S.T.M. Designation: D 52 – 20

ADOPTED, 1920.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 52; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

Scope

1. These specifications cover wooden paving blocks for pavements exposed to alternate wet and dry conditions, as distinguished from pavements which are used under cover and protected from atmospheric influences.

Kind of Timber

2. The wood, which shall be treated, shall be southern pine, Douglas fir, tamarack, Norway pine, hemlock, or black gum. Only one kind of wood shall be used in any one contract. The blocks shall be sound; shall be well manufactured, square-butted, and square-edged; and shall be free from unsound, loose, or hollow knots, knot holes, worm holes, and other defects such as shakes, checks, etc. that would be detrimental to the blocks.

Quality of Timber

3. (*a*) *Number of Annual Rings.*—The number of annual rings in the 1 in. which begins 2 in. from the pith of the block shall not be less than six, measured radially; provided, however, that blocks containing between five and six rings in this inch shall be accepted if they contain 33⅓ per cent or more summerwood. In case the block does not contain the pith, the 1 in. to be used shall begin 1 in. away from the ring which is nearest to the heart of the block.

(*b*) *Heartwood.*—The blocks in each charge shall contain an average of at least 70 per cent of heartwood. No one block shall be accepted that contains less than 50 per cent of heartwood.

Size of Blocks

4. The blocks shall be from 5 to 10 in. in length, but should preferably average two times the depth; they shall be .... in. in depth.[3] They may be from 3 to 4 in. in width, but in any one city square all of them shall be of uniform width. Permissible variations from the specified dimensions shall not

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-7 on Timber.

[2] Prior to adoption as standard, these specifications were published as tentative from 1918 to 1920, being revised in 1920. Editorially revised and rearranged in 1939.

[3] It is recommended that blocks 4 in. in depth be used for streets with very heavy traffic, and blocks 3½ in. in depth for streets with moderate traffic. For streets with light traffic, blocks 3 in. in depth may be used, but where 3-in. blocks are used no block shall be longer than 8 in.

exceed $\frac{1}{16}$ in. in depth and $\frac{1}{8}$ in. in width, except that in all cases the width shall be greater or less than the depth by at least $\frac{1}{4}$ in.

Preservative

5. The preservative used shall be coal tar paving oil or distillate oil, as specified by the purchaser.

Preservative Treatment

6. (*a*) The timber may be either air-seasoned or green, but should preferably be treated within three months from the time it is sawed. Green timber and seasoned timber shall not be treated together in the same charge. The blocks shall be treated in an airtight cylinder with the preservative specified by the purchaser. In all cases, whether thoroughly air-seasoned or green, they shall be first subjected to live steam at a temperature between 220 and 240 F.[4] for not less than 2 nor more than 4 hr. at the discretion of the treating plant operator, after which they shall be subjected to a vacuum of not less than 22 in. maintained for at least 1 hr. While the vacuum is still on, the preservative oil, heated to a temperature of between 180 and 220 F., shall be run in until the cylinder is completely filled, care being taken that no air is admitted. Pressure shall then be gradually applied not to exceed 50 psi. at the end of the first hour nor 100 psi. at the end of the second hour, and then maintained at not less than 100 psi. nor more than 150 psi. until the wood has absorbed the required amount of oil.[5]

(*b*) After this a supplemental vacuum, in which the maximum intensity reached is at least 20 in. and the time the vacuum is applied not less than 30 min., shall be applied. If desired, this vacuum may be followed by a short steaming period.

Penetration of Preservative

7. In any charge, blocks shall contain at least 16 lb. of water-free oil per cubic foot of wood at the completion of the treatment. The blocks after treatment shall show satisfactory penetration of the preservative, and in all cases the oil shall be diffused throughout the sapwood. To determine this, at least 25 blocks shall be selected from various parts of each charge and sawed in half perpendicular to the fibers through the center, and if more than one of these blocks show untreated sapwood, the charge shall be re-treated. After re-treating, the charge shall be again subjected to a similar inspection.

Handling Blocks After Treatment

8. Blocks shall preferably be laid in the street as soon as possible after being treated. If they cannot be laid immediately, provision shall be made to prevent them from drying out by stacking in close piles and covering them, and, if possible, by sprinkling them thoroughly at intervals. In any case, when they are not laid as soon as they are received at the site of the work, they shall be well sprinkled under the direction of the purchaser about two days before being laid. It is important to have the wood sufficiently wet to be swelled to its maximum size before it is laid.

Inspection at Plant

9. All material prescribed in these specifications and processes used in the manufacture of the blocks therefrom shall be subject to inspection, acceptance, or rejection at the plant of the manufacturer, which shall be equipped with all the necessary gages, appliances,

[4] In no case shall a steam pressure of 20 psi. be exceeded.

[5] This treatment is recommended for southern pine only. It is probably also suited to Norway pine, hemlock, black gum, and tamarack, but not to Douglas fir. Further recommendations on the treatment of these species are reserved for the future.

and facilities to enable the inspector to satisfy himself that the requirements of the specifications are being fulfilled.

Inspection at Site of Work

10. The purchaser shall have the further right to inspect the blocks after delivery at the site of the work, for the purpose of rejecting any blocks that do not conform to these specifications; except that the inspections at the plant shall be final with respect to the kind of wood, number of rings per inch, oil, and treatment.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: O7-1939

Standard Specifications for

STRUCTURAL WOOD JOIST AND PLANK, BEAMS AND STRINGERS, AND POSTS AND TIMBERS[1]

A.S.T.M. Designation: D 245 – 37

ADOPTED, 1937.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 245; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

These specifications were prepared jointly by the American Railway Engineering Association and the American Society for Testing Materials

GENERAL REQUIREMENTS

Applying to All Stress-Grades and Items

Manufacture

1. All material shall be well manufactured.

Quality of Wood

2. No piece of exceptionally light weight shall be permitted.

Decay

3. Only pieces consisting of sound wood free from any form of decay shall be acceptable, unless otherwise specified.

Slope of Grain

4. Slope of grain shall be measured over a distance sufficiently great to determine the general slope disregarding slight local deviations. Within the middle half of length of piece, slope of grain shall not be steeper than specified.

Holes

5. Knot holes and holes from causes other than knots shall be measured and limited as provided for knots.

Cluster Knots

6. Cluster knots and knots in groups shall not be permitted.

Knots in Joist and Plank

7. (*a*) *Knots on Narrow Faces.*—Size of knot on a narrow face shall be taken as the width between lines enclosing the knot and parallel to the edges of the piece. The only knots measured on narrow faces, except spike knots which cross the corners of side-

[1] Under the standardization procedure of the Society, these specifications are under the jurisdiction of the A.S.T.M. Committee D-7 on Timber.

[2] Prior to their present adoption as standard, these specifications were published as tentative from 1926 to 1927, being revised in 1927. They were adopted in 1927, revised in 1929, 1930, and 1933, but withdrawn and republished as tentative from 1936 to 1937. Editorially revised and rearranged in 1939.

cut pieces, shall be those that do not show on wide faces.

(*b*) *Knots on Wide Faces.*—Size of knot on a wide face shall be the average of its largest and smallest diameters. A spike knot which crosses a corner of a side-cut piece and contains the intersection of the adjacent faces, or which extends entirely across a face of a piece, shall be measured only on its end or ends, between lines parallel to the edges of the piece.

(*c*) *Permissible Increase in Knot Sizes.*—Size of knots on narrow faces and at edges of wide faces may increase proportionately from the size permitted in the middle third of the length to twice that size at ends of the piece. Size of knots on wide faces may increase proportionately from the size permitted at the edge to the size permitted along the center line.

(*d*) *Sum of Knots.*—Sum of sizes of all knots within the middle half of the length of any face, measured as specified in Paragraph (*a*) or (*b*) for the face under consideration, shall not exceed four and one-half times the size of the largest knot allowed on that face.

Knots in Beams and Stringers

8. (*a*) *Knots on Narrow Faces.*—Size of knot on a narrow face shall be taken as the width between the lines enclosing the knot and parallel to the edges of the piece except that when a knot on a narrow face extends into the adjacent one-fourth of the width of a wide face its least dimension shall be taken as its size.

(*b*) *Knots on Wide Faces.*—Size of knot on a wide face shall be its smallest diameter. Knots at the edges of wide faces shall be limited to the same sizes as on narrow faces but are measured as specified in this paragraph.

(*c*) *Permissible Increase in Knot Size.*—Size of knots on narrow faces and at the edges of wide faces may increase proportionately from the size permitted in the middle third of the length to twice that size at the ends of the piece, except that no knot shall exceed the size permitted along the center line of a wide face. Size of knots on wide faces may increase proportionately from the size permitted at the edge to the size permitted along the center line.

(*d*) *Sum of Knots.*—Sum of sizes of all knots within the middle half of the length of any face, measured as specified in Paragraph (*a*) or (*b*) for the face under consideration, shall not exceed four times the size of the largest knot allowed on that face.

Knots in Posts and Timbers

9. (*a*) *Knots on Either Face.*—Size of a knot on either face shall be half the sum of its largest and smallest diameters. A spike knot which crosses a corner of a side-cut piece and contains the intersection of the adjacent faces, or which extends entirely across a face of a piece, shall be measured only on its end or ends, between lines parallel to the edges of the piece.

(*b*) *Sum of Knots.*—Sum of sizes of all knots in any 6 in. of the length of piece, measured as specified in Paragraph (*a*), shall not be permitted to exceed twice the maximum permissible size of knot. Two knots of the maximum permissible size shall not be permitted in the same 6 in. of length on any face.

Shakes, Checks, Splits in Joist and Plank and Beams and Stringers

10. (*a*) Shakes, checks, and splits, when permitted in the grade specified later in these specifications, shall be measured at the ends of the piece. Only those within the middle half of the height shall be considered. (The height equals the width of the wide face.) Size of shake is the distance between the lines enclosing the shake and parallel to the wide faces of the piece. Per-

missible size is determined by the width of the narrow face of the piece.

(*b*) Checks and splits shall be measured and limited in the same way as shakes. The following limitations apply to both ends but only within the middle half of the height of the piece and within three times the height from the end. (The height equals the width of the wide face.) Size of checks within this portion of the piece shall be taken as their estimated area, along the horizontal section showing maximum area, divided by three times the height of the piece (Note). When checks on two parallel faces are opposite or approximately so, the sum of their sizes shall be taken. The sum of sizes of shakes, checks, and/or splits shall not exceed the permissible size of shake.

(*c*) Checks extending entirely across the end within the middle half of the height shall not extend into the piece at the center of width of end a distance greater than the size of the allowable shake.

Shakes, Checks, Splits in Posts and Timbers

11. (*a*) Shakes, checks, and splits, when permitted in the grade specified later in these specifications, shall be measured at the ends of the piece. Size of a shake is the distance between the lines enclosing the shake and parallel to a pair of opposite faces.

(*b*) Checks and splits shall be measured and limited in the same way as shakes. Size of checks within three times the width of the piece from either end shall be taken as their estimated area, along the longitudinal section showing maximum area, divided by three times the width of the piece (Note). Sum of sizes of shakes, checks, and/or splits shall not exceed the permissible size of shake.

(*c*) Checks extending entirely across the end shall not extend into the piece at the center of width of end, a distance greater than the size of allowable shake.

NOTE.—A practical method of inspection in the field to determine the size of checks and splits under the above specification is as follows:

The size of checks within the specified portion of the piece shall be taken as the sum of seven depth measurements, one on the end and three on each side, divided by three. Each measurement shall represent the greatest depth of *any* check within the center half of the height; the measurement on the end shall be taken at the center of the width, and the three measurements on each side shall be taken at distances of one, two, and three times the height of the piece from the end in joist, plank, beams and stringers, and the width of the piece from the end in posts and timbers. Each measurement shall be determined by the penetration into the piece of a probe $\frac{1}{64}$ in. in thickness and $\frac{1}{2}$ in. in width.

OPTIONAL AND ADDITIONAL REQUIREMENTS

Applying to Stress-Grades when Heartwood or Wane, and When Density and Close Grain Are Required

Heartwood Requirements

12. (*a*) When heartwood material is desired it shall be specified in terms of the amount or percentage of heartwood on the girth, or on each face, side, or edge, measured at the point where the greatest amount of sapwood occurs.

(*b*) For all timber to be pressure treated there shall be no heartwood requirement and the amount of sapwood shall not be limited.

Wane

13. When wane is not desired, the specifications should state "Square Edge."

Density (when required) of Dense Douglas Fir

14. (*a*) Dense Douglas Fir shall average on either one end or the other of each piece not less than six annual rings

per inch, and, in addition, one-third or more summerwood (the darker, harder portion of the annual ring) measured over 3 in. on a line at right angles to the annual rings, located as described below. The contrast in color between summerwood and springwood shall be distinct.

(*b*) Coarse-grained material excluded by this rule shall be accepted as dense if averaging one-half or more summerwood.

(*c*) In boxed-heart pieces the line shall run from the pith to the corner farthest from the pith, except that when the line is not representative it shall be shifted sufficiently to present a fair average, but the distance from the pith to the beginning of the 3-in. portion of the line shall not be changed. When the least dimension is 6 in. or less, the 3-in. portion of the line shall begin at a distance of 1 in. from the pith. When the least dimension is more than 6 in., the 3-in. portion of the line shall begin at a distance from the pith equal to one-fourth the least dimension of the piece.

(*d*) In side-cut pieces (pith not present) the center of the 3-in. portion of the line shall be at the center of the end of the piece; if a 3-in. portion of the line cannot be obtained, the measurement shall be made over as much of a 3-in. portion as is available.

(*e*) In case of disagreement, two radial lines shall be chosen and the summerwood and number of rings shall be taken as the average on these lines.

Density (when required) of Dense Longleaf or Shortleaf Yellow Pine

15. (*a*) Dense longleaf or shortleaf yellow pine shall average on either one end or the other of each piece not less than six annual rings per inch, and, in addition, one-third or more summerwood (the darker, harder portion of the annual ring), measured over the third, fourth, and fifth inches of a radial line from the pith. The contrast in color between summerwood and springwood shall be sharp and the summerwood shall be dark in color, except in pieces having considerably above the minimum requirement for summerwood.

(*b*) Coarse-grained material excluded by this rule shall be accepted as dense if averaging one-half or more summerwood.

(*c*) The radial line shall be representative of the average growth of the cross-section. In case of disagreement, two radial lines shall be chosen, and the number of rings per inch and percentage of summerwood shall be taken as the average determined on these lines.

(*d*) In boxed-heart pieces the measurement shall be made over the third, fourth, and fifth inches from the pith along the radial line.

(*e*) In material containing the pith, but not a 5-in. radial line, which is less than 2 by 8 in. in section or less than 8 in. in width, that does not show over 16 sq. in. on the cross-section, the inspection shall apply to the second inch from the pith. In larger material that does not show a 5-in. radial line, the inspection shall apply to the three inches farthest from the pith.

(*f*) In cases where timbers do not contain the pith and it is impossible to locate it with any degree of accuracy, the same inspection shall be made over 3 in. on an approximate radial line beginning at the edge nearest the pith in timbers over 3 in. in thickness and on the second inch nearest the pith in timbers 3 in. or less in thickness.

Close Grain (when required) of Close-Grained Douglas Fir, or Redwood

16. (*a*) Close-grained Douglas fir shall average on either one end or the other of each piece not less than six nor more than twenty annual rings per inch; close-grained redwood shall average on

either one end or the other of each piece not less than ten nor more than thirty-five annual rings per inch. The rings shall be measured over 3 in. on a line at right angles to the annual rings, located as described below.

(*b*) In boxed-heart pieces the line shall run from the pith to the corner farthest from the pith except that when the line is not representative it shall be shifted sufficiently to present a fair average, but the distance from the pith to the beginning of the 3-in. portion of the line shall not be changed. When the least dimension is 6 in. or less, the 3-in. portion of the line shall begin at a distance of 1 in. from the pith. When the least dimension is more than 6 in., the 3-in. portion of the line shall begin at a distance from the pith equal to one-fourth the least dimension of the piece.

(*c*) In side-cut pieces (pith not present) the center of the 3-in. portion of the line shall be at the center of the end of the piece. If a 3-in. portion of the line cannot be obtained, the measurement shall be made over as much of a 3-in. portion as is available.

(*d*) In case of disagreement, two radial lines shall be chosen and the number of rings shall be taken as the average on these lines.

(*e*) Pieces of Douglas fir averaging five rings, or more than twenty, shall be accepted if they contain one-third or more summerwood.

STRESS-GRADES

I. Joist and Plank

= Extreme fiber stress in bending in pounds per square inch for continuously dry locations.

APPENDIX

The following three tables summarizing standard sizes, stress-grades, and working stresses for joist and plank, beams and stringers, and posts and timbers are appended for information. They offer a valuable key to different structural grades.

TABLE I.—STANDARD SIZES, STRESS-GRADES, AND WORKING STRESSES FOR STRUCTURAL JOIST AND PLANK.

Standard Sizes

Nominal thicknesses	2, 3, and 4 in.
Permissible minimum rough thicknesses in not to exceed 20 per cent of pieces in any one shipment:	
2 in.	$\frac{1}{8}$ in. off
3 and 4 in.	$\frac{3}{16}$ in. off
Dressed thicknesses, S1S or S2S	$\frac{3}{8}$ in. off
Nominal widths	4 in. and wider
Permissible minimum rough widths in not to exceed 20 per cent of pieces in any one shipment:	
4 and 6 in.	$\frac{3}{16}$ in. off
8 in. and wider	$\frac{1}{4}$ in. off
Dressed widths, S1E or S2E:	
4 and 6 in.	$\frac{1}{8}$ in. off
8 in. and wider	$\frac{1}{2}$ in. off

Standard Stress-Grades and Working Stresses

(Continuously Dry Locations)

GRADES AND SPECIES	FIBER STRESS IN BENDING OR TENSION, PSI.	MAXIMUM HORIZONTAL SHEAR, PSI.	COMPRESSION PERPENDICULAR TO GRAIN, PSI.	MODULUS OF ELASTICITY, PSI.
1800 lb. *f* Dense Douglas Fir (Coast and Inland)	1800	120	380	1 600 000
1800 lb. *f* Dense Longleaf or Dense Shortleaf Southern Pine	1800	120	380	1 600 000

TABLE II.—STANDARD SIZES, STRESS-GRADES, AND WORKING STRESSES FOR STRUCTURAL BEAMS AND STRINGERS.

Standard Sizes

Nominal thicknesses	5 in. and thicker
Permissible minimum rough thicknesses in not to exceed 20 per cent of pieces in any one shipment:	
5 and 6 in.	$\frac{3}{16}$ in. off
8 in. and wider	$\frac{1}{4}$ in. off
Dressed thicknesses, S1S or S2S	$\frac{1}{2}$ in. off
Nominal widths	8 in. and wider
Permissible minimum rough widths in not to exceed 20 per cent of pieces in any one shipment	$\frac{1}{4}$ in. off
Dressed widths, S1E or S2E	$\frac{1}{2}$ in. off

Standard Stress-Grades and Working Stresses

(Continuously Dry Locations)

GRADES AND SPECIES	FIBER STRESS IN BENDING OR TENSION, PSI.	MAXIMUM HORIZONTAL SHEAR, PSI.	COMPRESSION PERPENDICULAR TO GRAIN, PSI.	MODULUS OF ELASTICITY, PSI.
1800 lb. *f* Dense Douglas Fir (Coast and Inland)	1800	120	380	1 600 000
1800 lb. *f* Dense Longleaf or Dense Shortleaf Southern Pine	1800	120	380	1 600 000
1600 lb. *f* Close-Grained Douglas Fir (Coast)	1600	100	345	1 600 000
1600 lb. *f* Dense Longleaf or Dense Shortleaf Southern Pine	1600	120	380	1 600 000
1600 lb. *f* Close-Grained Redwood	1600	80	267	1 200 000
1400 lb. *f* Tidewater Red Cypress	1400	120	300	1 200 000
1400 lb. *f* Oak	1400	120	500	1 500 000
1400 lb. *f* Dense Longleaf Southern Pine	1400	100	380	1 600 000
1400 lb. *f* Close-Grained Redwood	1400	80	267	1 200 000
1200 lb. *f* Dense Shortleaf Southern Pine	1200	100	380	1 600 000
1200 lb. *f* Close-Grained Redwood	1200	70	267	1 200 000
1100 lb. *f* Port Orford Cedar	1100	80	250	1 200 000
1100 lb. *f* Tidewater Red Cypress	1100	100	300	1 200 000
1100 lb. *f* Oak	1100	100	500	1 500 000
1000 lb. *f* Western Red Cedar	1000	100	200	1 000 000

TABLE III.—STANDARD SIZES, STRESS-GRADES, AND WORKING STRESSES FOR STRUCTURAL POSTS AND TIMBERS.

Standard Sizes

Nominal thicknesses	5 in. and thicker
Permissible minimum rough thicknesses in not to exceed 20 per cent of pieces in any one shipment:	
5 and 6 in.	$\frac{3}{16}$ in. off
8 in. and wider	$\frac{1}{4}$ in. off
Dressed thicknesses, S1S or S2S	$\frac{1}{2}$ in. off
Nominal widths	5 in. and wider
Permissible minimum rough widths in not to exceed 20 per cent of pieces in any one shipment:	
5 and 6 in.	$\frac{3}{16}$ in. off
8 in. and wider	$\frac{1}{4}$ in. off
Dressed widths, S1E or S2E	$\frac{1}{2}$ in. off

Standard Stress-Grades and Working Stresses

(Continuously Dry Locations)

GRADES AND SPECIES	COMPRESSION PARALLEL TO GRAIN, SHORT COLUMNS, PSI.	
1300 lb. *c* Dense Douglas Fir (Coast and Inland)	1300	
1300 lb. *c* Dense Longleaf or Dense Shortleaf Southern Pine	1300	
1200 lb. *c* Tidewater Red Cypress	1200	
1200 lb. *c* Close-Grained Douglas Fir (Coast)	1200	
1200 lb. *c* Dense Longleaf or Dense Shortleaf Southern Pine	1200	
1200 lb. *c* Close-Grained Redwood	1200	
1100 lb. *c* Douglas Fir (Coast)	1100	For stresses in compression
1100 lb. *c* Oak	1100	perpendicular to grain and
1100 lb. *c* Close-Grained Redwood	1100	modulus of elasticity, see
1000 lb. *c* Port Orford Cedar	1000	values in Table II for
1000 lb. *c* Tidewater Red Cypress	1000	Beams and Stringers.
1000 lb. *c* Oak	1000	
1000 lb. *c* Dense Longleaf Southern Pine	1000	
1000 lb. *c* Close-Grained Redwood	1000	
900 lb. *c* Port Orford Cedar	900	
900 lb. *c* Dense Shortleaf Southern Pine	900	
800 lb. *c* Western Red Cedar	800	

The detailed reasoning basic to these grades will be found by a study of a report of the U. S. Forest Products Laboratory, U. S. Department of Agriculture *Miscellaneous Publication No. 185*, entitled "Guide to the Grading of Structural Timbers and the Determination of Working Stresses," February, 1934. Reference should also be made to the "Working Stresses" appearing in the Appendix to the Standard Specifications for Structural Wood Joist and Plank, Beams and Stringers, and Posts and Timbers (A.S.T.M. Designation: D 245 – 33) of the American Society for Testing Materials, 1933 Book of A.S.T.M. Standards, Part II, p. 384.

APPROVED AS
AMERICAN STANDARD
BY THE AMERICAN STANDARDS ASSOCIATION
ASA NO.: 04a-1927

Standard Methods of

TESTING SMALL CLEAR SPECIMENS OF TIMBER[1]

A.S.T.M. Designation: D 143 – 27

ADOPTED, 1927.[2]

This Standard of the American Society for Testing Materials is issued under the fixed designation D 143; the final number indicates the year of original adoption as standard or, in the case of revision, the year of last revision.

The everyday use of timber for multitudinous purposes makes manifest a continual need of data on its mechanical properties. The great variety of species, the variability of the material, the continually changing conditions of supply, the many factors affecting test results, all combine to make the technique of testing wood unique in its complexity.

In the preparation of this procedure for testing small clear specimens, consideration was given both to the desirability of adopting methods which would yield results comparable to those already available and to the possibility of embodying such improvements as experience has shown desirable. In view of the many thousands of tests made under a single comprehensive plan by the U. S. Forest Service, the Forestry Branch of the Department of the Interior, Canada, and other similar organizations, the procedure naturally conforms closely to the methods used by these institutions. This procedure is the outgrowth of a study of both American and European experience and methods. Its general adoption will tend toward a world-wide unification of results, permitting an interchange and correlation of data, and will establish the basis for a cumulative body of fundamental information on the timber species of the world.

These methods represent the entire procedure from selection of the trees to the manipulation of the test, thus controlling factors, such as the size and proportion of test specimens and rate of loading, which may influence results. No attempt has been made to cover methods of computation and analysis, as these questions may be considered independently at any time. Such sample data and computation sheets and cards have been incorporated, however, as were thought to be of assistance to the investigator in systematizing records.

---

[1] Under the standardization procedure of the Society, these methods are under the jurisdiction of the A.S.T.M. Committee D-7 on Timber.

[2] Prior to adoption as standard, these methods were published as tentative from 1922 to 1927, being revised in 1924.

Purpose of Tests

1. Tests on small clear specimens of wood are made to afford:

(*a*) Data for comparing the mechanical properties of various species.

(*b*) Data for the establishment of correct strength functions which, in conjunction with results of tests of timbers in structural sizes,[3] afford the basis for fixing allowable stresses.

(*c*) Data upon which to determine the influence on the mechanical properties of such factors as density, locality of growth, position in cross-section, height of timber in the tree, change of properties with seasoning, and change from sapwood to heartwood.

Kind of Tests

2. The principal mechanical tests are static bending, compression parallel to grain, impact bending, compression perpendicular to grain, hardness, shear parallel to grain,[4] tension perpendicular to grain, cleavage, and tension parallel to grain. These tests are made on both green and air-dry material as specified in these methods. In addition, such physical properties as specific gravity, radial shrinkage, tangential shrinkage, and shrinkage in volume are determined.

COLLECTION OF MATERIAL

Selection

Authentic Identification

3. The material shall be from trees selected in the forest by one qualified to identify the species.

Selection and Number of Trees

4. For each species to be tested from a given locality, at least five representative trees of merchantable size and of approximately average age shall be selected.

Selection and Number of Bolts

5. The material from five trees of each species from a given locality shall be selected as follows:

(*a*) From one tree, the entire merchantable bole, if not over 16 ft. in length;[5] if over 16 ft. in length, four 4-ft. sections or bolts, the first to be taken at the stump, the second and third at distances of one-eighth and three-eighths, respectively, of the merchantable length above the stump or as near thereto as possible; and the fourth at the top of the merchantable length.

(*b*) From two trees, the 8-ft. section next above the 8-ft. butt log.

(*c*) From two trees, the 4-ft. section next above the 12-ft. butt log.

Substitution of Flitches for Bolts

6. In cases where the logs or bolts are over 36 in. in diameter, a single flitch 6 in. in thickness, taken through the pith in a north and south direction and representing the full diameter of the log, may be substituted, in the same length, for the full log or bolt specified in Section 5.

Selection from Small Trees

7. When the trees are relatively small in diameter, material in addition to that provided for in Sections 5 and 6 shall be collected, whenever possible, to insure a sufficient number of tests to give a good average for the species.

Field Marking

Tree Designation

8. Each tree shall be given an arabic number, the numbering in any given

[3] See Standard Methods of Static Tests of Timbers in Structural Sizes (A.S.T.M. Designation: D 198), which appears in this publication, see Contents in Numeric Sequence of A.S.T.M. Designations at front of book.

[4] The test for shearing strength perpendicular to the grain (sometimes termed "vertical shear") is not included as one of the principal mechanical tests since in such a test the strength is limited by the shearing resistance parallel to the grain.

[5] This tree is intended to furnish test material for studying, among other things, the variation of properties with height in trees and provides for this purpose a 4-ft. section from different heights. Experience has shown that four sections or bolts, each 4 ft. in length, will usually be sufficient for studying the influence of height in tree on the mechanical properties.

shipment to be consecutive for trees of a given species.

Bolt Designation

9. Each 4 ft. of length of a tree or log shall be considered a "bolt." Bolts shall be designated by small letters, beginning with *a* for the 4-ft. section next above the stump. Bolt letters, given a shipment number or other designation.

Field Descriptions

Field Descriptions

13. (*a*) Complete field notes describing the material shall be fully and carefully made by the collector. These

TABLE I.—SHIPMENT DESCRIPTION FIELD NOTES.

Project No., *124* — Shipment No., *323*
Tree No., *10* — Species, *Lodgepole pine*
Locality cut: State, *Montana* — County, *Jefferson*
Township, *6 N., R. 7 W., M. P. M.* — Date cut, *Oct. 10, 1914*
Slope, *Moderate* — Absolute elevation, *6600 ft.* — Aspect, *southeasterly*
Undergrowth, *None* — Soil, *Deep, fresh-decomposed granite*
Height, *73.9 ft.* — Seedling or sprout, *Seedling* — Age, *140 yr.*
Crown, *Length 25 ft., width 12 ft.* — D.B.H. *11.1 in.*
Stem, *Sound, smooth, clear, length 20 ft.* — Date sawed, *Oct. 10, 1914*
How and when transported from woods, *By sleigh and wagon, Oct. 13 to 15, 1914*

LIST OF SPECIMENS SAWED.

Log Number	Bolts	Length, ft.	Diameter Inside Bark		Volume	Footage, b. m.	Weight, Oct. 15, lb.
			Butt, in.	Top, in.			
1	bcd	12.1	11	9.6	..	..	336
2	efg	12.1	9.6	8.9	..	..	289
3	hij	12.1	8.9	7.7	..	..	242
4	klm	12.1	7.7	6.1	..	..	176
5	nop	12.1	6.1	3.1	..	..	95

REMARKS: *Stump height, 1.0 ft. Butt off on account of frost crack 3.0 ft. Length of top above last section taken, 9.4 ft. Total age, 140 yr. Tree was dominant throughout life. Rate of growth, regular and good average for Site I. Lower slope type, although of more than average height for the age and diameter found on poorer sites.*

therefore, indicate position with respect to height in tree.

Manner of Marking

10. The tree number and bolt designation shall be plainly marked upon each log selected by the collector. Thus the 16-ft. butt log of Tree No. 2 would be designated *2abcd*. Steel dies are recommended for marking the butt end of the logs.

Indication of Cardinal Point

11. The north side of each log shall be indicated in some convenient manner.

Shipment Number

12. All material collected from a given locality and shipped at one time shall be notes shall, in general, supply data as outlined in Table I.

(*b*) Photographs of the standing trees selected shall be taken.

Preparation for Shipment

Preparation for Shipment

14. (*a*) The bark will be left on each log, and care shall be taken to keep the bark intact. The ends of the logs shall be carefully painted to retard or prevent end drying and end checking.

(*b*) Record shall be made of the shipment routing, bill of lading, kind of shipment, date of shipment, and condition of material when shipped.

(*c*) Record shall also be made of date of receipt of shipment at destination, its condition, and method of storage.

to artificial heat. In addition they should preferably be protected from the sun.

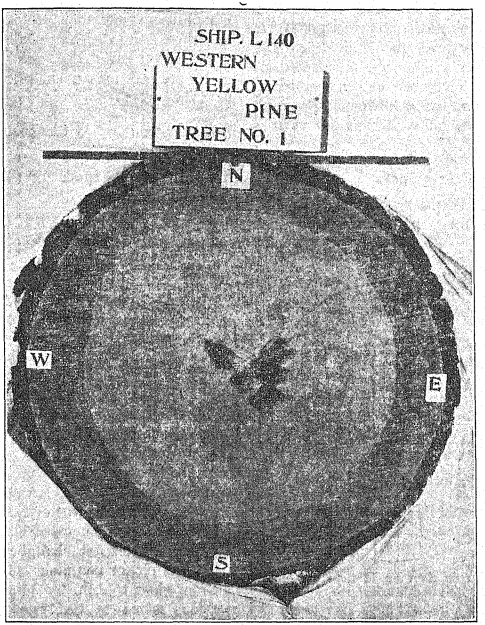

FIG. 1.—Section of Log Selected for Test Material.

DISPOSITION AT DESTINATION

Storage of Logs at Destination

Storage of Logs

15. Material shall not be kept in the bolt or log form long enough to permit damage by checks, decay, stains, or insect attack. The logs shall be piled on skids, free from contact with the soil, and shall not be stored where subjected

Photographing, Sawing and Final Marking

Photographing Ends of Bolts

16. The top end of each *d* or *c-d* bolt shall be photographed. It is suggested that a rule be so placed on the log as to indicate the scale of the photograph and that the cardinal points be indicated on the cross-section. Fig. 1 shows a photograph of this kind.

Sawing of Bolts

17. (*a*) All bolts shall be marked on the top end into 2½ by 2½-in. squares as shown in Fig. 2, and sawed into nominal 2½ by 2½-in. sticks. The letters *N*, *E*, *S*, and *W* indicate the cardinal points.

(*b*) When flitches are substituted for bolts (Section 6), the same general marking and numbering scheme of Paragraph (*a*) shall be followed in so far as it is applicable.

Marking of Test Sticks

18. All test sticks shall bear the shipment number, the tree number, stick

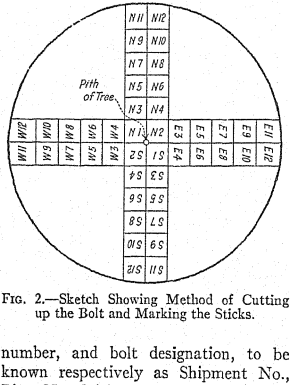

FIG. 2.—Sketch Showing Method of Cutting up the Bolt and Marking the Sticks.

number, and bolt designation, to be known respectively as Shipment No., Piece No., Stick No., and mark. Thus, 400-1-*N*4*d* represents Stick *N*4 of Bolt *d*, Tree 1, Shipment 400.

Matching for Air-dry Tests

Composition Bolts

19. In the tests made to determine the effect of air-drying on strength, the sticks from the *c* bolt shall be interchanged with those of the *d* bolt of the same tree to form two composition bolts, each composition bolt being complete and being made of equal portions of *c* and *d* bolts.[6] The sticks from one of these composition bolts shall be tested green and those from the other shall be tested after air-drying. The sticks tested either green or air-dry shall be regarded as if they were from the same bolt.

Schedule for Forming Composition Bolts
